This abstract shows that out of every 47 deaths not far from 21 were neither diagnosed nor classified. This is merely one of the incidents connected with the present imperfect state of the registration, and absolute want of knowledge is better than error in this case.

6. There is very little sanitary information in this year's report on the epidemic history of the year and its concomitants. We shall therefore confine our remarks mainly to any points requiring notice in the statistics of the chief diseases.

Cholera.—The following abstract gives the statistical history of this epidemic disease for the last 17 years :—

Years.	Deaths from Cholera.	Years.	Deaths from Cholera.
1866	200,961	1875	94,546
1867	38,205	1876	148,198
1868	8,063	1877	357,430
1869	21,034	1878	47,767
1870	55,867	1879	13,296
1871	17,656	1880	818
1872	13,247	1881	9,446
1873	840	1882	23,604
1874	313		

This table shows the end of a great epidemic in 1868; next, a four years' epidemic, ending in 1872, during the prevalence of which 107,804 people died of cholera. Next follow two quiescent years, and then a great epidemic lasting five years, and including the famine period, during which 660,632 deaths from cholera were registered. The following year, 1880, was one of quiescence, and the next two years, 1881–82, appear as if they formed the beginning of another epidemic.

7. The outbreak of 1882, with its 23,604 deaths, presents some points of interest. Cholera prevailed with great severity in the endemic area of Lower Bengal; but as this cholera showed no disposition to pass directly from the river deltas into the Central Provinces, so it passed over all the districts of the north-east of Madras, and did not appear in force in any of them until April. But in the meantime cholera had appeared in strength in Madras district and the regions of the presidency south of the latitude of the city in January, February, and March. The first two months of 1882 bore the weight of the epidemic in these regions, and it faded away towards the end of the year, with a slight tendency to increase after September. In the far north-eastern districts the maximum mortality was reached in June, and in the far south-western district of Malabar the highest death-rates took place in August and September.

This epidemic bore no mark of cholera invading Madras by way of the north-east. It appeared as if the disease had descended upon the attacked districts, as it apparently did on certain parts of Bombay. There was no continuity of surface attacked, and there were large areas of country which escaped, or nearly so. No deaths were reported from four districts. Out of 226 registration circles 145 were attacked, but the whole mortality of the year was furnished by 3,262 villages out of 47,325 in the presidency.

8. The next abstract shows the cholera deaths registered in each month of 1882:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	10,794	July	550
February	4,193	August	780
March	1,081	September	644
April	491	October	777
May	590	November	799
June	843	December	2,062

The cholera epidemic shown in the table did not, however, begin in January 1882. We must go back to the preceding year in order to arrive at the true history of the outbreak, which was as follows:—

During the first six months of 1881 there were 401 deaths from cholera in the presidency. The disease was not epidemic, and it ended in four deaths in July and one death in August. The true epidemic began with four deaths in September, followed by 297 in October, 1,323 in November, and 7,403 in December, and thence to the monthly deaths in 1882, shown in the table.

9. The comparative death-rates of town and country registration circles stood as follows:—There are 72 towns, with an aggregate population of 1,498,290, of which 45 registered 3,932 cholera deaths, equal to a death-rate of 2·6 per 1,000 taken over the whole town population. Twenty-seven towns escaped altogether, and in others the deaths were very few in number. In not a few towns, however, the outbreaks of cholera partook of a distinctly local character, and led to very high death-rates, such as 5, 7, or 9 per 1,000. One town in Malabar, Ponani, with a population of 17,453, had 161 deaths from cholera, a rate of 14 per 1,000. The highest cholera death-rate of the year was returned from Periyaculam, a town with 13,468 inhabitants, in Madura district, which lost 375 people from the epidemic, equal to a death-rate of 27·8 per 1,000. To show the local nature of these two severe outbreaks, it may be stated that the death-rate from cholera in Malabar district, within which the former town is situated, was 0·4 per 1,000, and the rate for Madura, within which was the latter, was 1·6 per 1,000.

In the rural circles, with a population of 27,388,812, there were 19,672 cholera deaths registered, or 0·7 per 1,000 of the population. As has been already stated, four districts escaped cholera altogether. In three others there were in all 18 deaths, so that the cholera epidemic of 1882 fell on the population of 15 districts out of 22, and of the attacked districts two yielded rates of 1 per 1,000, two of 1·1 per 1,000, one of 1·6, and one, Tanjore, of 4·3 per 1,000. This district has a population of 1,789,494, and lost 7,767 of them from cholera. Two of its towns had death-rates below the district average, but the other three exceeded it, and two of them more than doubled the district rate.

10. This class of facts points to the partial distribution of the epidemic, and to its much greater severity in certain circles of registration than in others. In other words, the distribution of cholera in affected regions was general, but its severity was local. And this involves the question of local predisposing causes during the prevalence of an epidemic, instances of which will be given in subsequent paragraphs.

11. *Small-pox.*—The following tabular statement gives the statistics of small-pox mortality in Madras Presidency for a period of 12 years:—

Years.	Deaths from Small-pox.	Deaths per 1,000 of Population.
1871	20,823	0·8
1872	39,074	1·2
1873	51,782	1·7
1874	48,343	1·5
1875	24,775	0·8
1876	23,469	0·8
1877	88,321	3·0
1878	56,360	1·9
1879	17,840	0·6
1880	14,529	0·5
1881	15,776	0·5
1882	20,159	0·6

This abstract shows a very general prevalence of small-pox in Madras Presidency, with periods of aggravation rather than of decline, and high death-rates in individual years, of which the famine years 1877–78 afford remarkable examples. Of the deaths in 1882 there were 4,713 under 1 year of age, 9,286 between 1 and 12 years, and 6,160 above 12 years. All the districts suffered in 1882, and small-pox deaths were registered in 212 circles out of 226. The number of attacked villages is not given, but 57 towns out of 72 suffered, some of them severely. The country circles yielded 17,907 deaths, or 0·6 per 1,000, while the towns registered 2,252 deaths, or 1·5 per 1,000. The highest district rate, 2·9 per 1,000, was returned from Ganjam, and all the 22 districts, with three exceptions, returned rates under 1 per 1,000. In the towns the rates were generally much higher than in the country circles, and one town, Coimbatore, yielded the very high rate of 10·7 per 1,000. This town has a municipal government. The births registered in Coimbatore in 1882 were 1,318. The successful vaccinations amounted to 1,644, of which 728 were under 1 year of age, or about half the births, and out of 378 small-pox deaths 119 were under 1 year of age.

12. The following five years' abstract shows the relation of vaccination work to births and to deaths from small-pox, but the births registered obviously do not include the numbers born:—

Years.	Registered Births.	Total Vaccinated.	Deaths from Small-pox.
1878	348,657	521,760	56,360
1879	477,762	469,744	17,840
1880	659,991	659,759	14,529
1881	731,866	601,222	15,776
1882	751,104	661,133	20,159
Total	2,969,380	2,913,618	124,664

According to these figures, the vaccination work has nearly averaged the registered births during five years, but the vaccinations appear to include re-vaccinations. The per-centages of successful operations have been for 1882, 92·8 for vaccinations, and 45·8 for re-vaccinations. The five years' average of successful operations has been 14·8 per 1,000 of the population, and the five years' average small-pox mortality has been 4·2 per 1,000. For the municipal towns the results from some cause or other have not been so favourable. Their vaccinations have averaged 38·5 per 1,000 of the population, and their small-pox deaths 2·5 per 1,000 for the same five years.

13. The vaccine establishment for 1882 was as follows:—

Inspector of vaccination and Deputy Sanitary Commissioner	1
Deputy Inspectors, 1st class	31
" " 2nd class	19
Vaccinators, 1st class	245
" 2nd class	375
Probationers	112
Peons	37

The total cost of vaccination service in 1882 was Rs. 1,65,456 15 10, and the cost of each successful case was As. 4 6.

14. The small-pox deaths registered in each month of 1882 gave the following results :—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	1,668	July	1,446
February	1,819	August	1,598
March	2,180	September	1,380
April	1,905	October	1,585
May	1,662	November	1,540
June	1,449	December	1,987

These deaths were returned month by month from every district, except South Canara, which had no deaths in January, February, and March, and Nellore, which escaped in July, August, and September. Practically, the year's epidemic covered the entire surface of the presidency, and the figures in this abstract show that the epidemic was by no means at an end in December, but would pass on to 1883.

In a preceding table we have given the annual small-pox mortality for a series of years, and if we leave out the exceptional years of famine and scarcity, 1877–78, it will be seen that of recent years there has been a decline in the death-rates from this epidemic disease, probably due in part to vaccination, but it is evident that considerable advance is required in this protective measure, as well as in the general sanitary improvement of towns and villages. The two measures ought to go hand in hand.

15. *Fever.*—The relative importance of different epidemic diseases in Madras to the public interests is well put by the Sanitary Commissioner in the following paragraph of the present report :—

"If we total up the number of deaths returned under the head of fever for the past 14 years we "get the appalling number of 3,269,522, whilst cholera, which creates much more fear and alarm, "gives us only 787,684, and small-pox 464,124," and to this estimate of the far greater importance of fever must be added this other fact, that every death from fever represents from 20 to 30 attacks, with their consequent diminution of working power in the sufferers.

16. If fever diagnosis and death registration were alike trustworthy we should be compelled to admit a large increase in the annual fever deaths of late years. The Sanitary Commissioner gives a table which shows that the lowest fever death-rate in 17 years was registered in 1866, the first year in the series. From this year, with 110,102 fever deaths, the deaths went on increasing, and in 1872 they had reached 214,148. Their numbers since then have been as follow :—

Years.	Fever Deaths.	Years.	Fever Deaths.
1873	222,842	1878	374,448
1874	226,220	1879	285,477
1875	252,042	1880	209,940
1876	230,092	1881	203,542
1877	469,241	1882	188,561

The years 1877–78 had exceptionally high fever-rates due to the famine, but allowing for this event the record is a sorrowful one enough, and affords an index to the kind of improvements needed in local drainage of village sites, better dwellings, better water, and improved tillage.

17. In 1882 the whole presidency suffered from fever prevalence, which is shown by the fact that all the 226 registration circles, with one solitary exception, returned fever deaths. The number of attacked villages is not available, but it may be safely stated that few escaped the disease. All the 72 towns returned fever deaths. Their average fever death-rate was 5·4 per 1,000, while the district rate averaged 6·5 per 1,000, which was also the general fever death-rate for the whole presidency. This was, however, lower than the previous five years' average, which was 9 per 1,000.

18. Fever mortality varied greatly in different districts. In Tanjore, for instance, it was only 1·7 per 1,000, with a previous five years' average of 2·5 per 1·000, while in Kurnool the fever death-rate was 13 per 1,000, with a previous five years' ratio of 22·1 per 1,000. The question suggests itself whether there be any local causes for these great differences in liability.

Take again the case of Nilgiri district. Why at such an elevation above sea-level should there have been a fever death-rate of 10·6 per 1·000 with a previous five years' ratio of 12·2 per 1,000? and why should the town of Ootacamund in this same district have yielded a fever death-rate in 1882 of 11·7 per 1,000? This town has a municipality, and yet its fever death-rate in 1882 would rank it among the most unhealthy towns of Madras. These and similar facts have been long known, but it is necessary to call attention to them from time to time as proving backwardness in sanitary work. On the other hand, we have an instance of Guntur, an improved municipal town in Kistna district, which returned a fever death-rate in 1882 of 2·8 per 1,000, while the district rate was 9·1 per 1,000, with a preceding five years' average of 8·8 per 1,000.

19. It is not easy to estimate the influence of rainfall on these local rates, because, generally speaking, this is determined by the presence of purely local conditions. We may, however, introduce the monthly fever mortality alongside the average monthly rainfall for the whole presidency to give a general idea of their relation to each other :—

Months.	Rainfall.	Fever Deaths.
	Inches.	
January	1·02	17,150
February	·04	15,008
March	·09	15,847
April	1·06	13,163
May	3·83	14,903
June	5·84	14,043
July	8·35	14,775
August	6·04	14,804
September	5·23	15,736
October	5·59	15,369
November	10·84	17,148
December	1·28	20,615
Total	37·33	98,447

The rainfall in this table represents the average of 233 places of observation, and the fever deaths of 225 circles of registration, both scattered over the whole presidency; nevertheless, as already stated, the fever death-rate varied greatly in different districts, leading to the conclusion that the effects of rain are very much under the influence of local conditions of soils, subsoils, and drainage facilities. A striking proof of this connexion between water-logging and drainage defects in localities is afforded by the case of the Kunathur fever, the local causes of which we described in a former memorandum. The matter was taken in hand by the collector of Chingleput, improvements were effected, and the Sanitary Commissioner describes the results in the present report. Referring to a previous report, in which he says will be found "Inspection notes on Kunathur and neighbouring villages, reported by "the collector of Chingleput to be desolated by an epidemic fever, with remedies suggested. It is "gratifying to be able to insert the following communication from the energetic collector, Mr. Price, "as the results of the measures carried out to remedy the state of things then existing:—'The long "'protracted outbreak of fever at Kunathur in the Saidapet taluk disappeared during the year, and "'the special medical staff employed was withdrawn.'" This was an instance of a most severe and fatal endemic fever of an aggravated type breaking out in a group of localities in an otherwise feverish country, where from local circumstances the subsoil surroundings and conditions had led to excessive damp or wet in the dwellings in addition to the usual insanitary state of Indian villages. The general rainfall had been about 46¼ inches, and the district fever death-rate 7·2 per 1,000, by no means an excessive rate for India, and yet for the aggravating causes stated the village deaths were those of a local pestilence.

The practical results of this experience have shown that, in dealing with epidemics in India, we must descend to details instead of contenting ourselves with general facts, and attack the evils in the villages and houses.

20. *Bowel complaints.*—Fatal diseases classed under this head were reported from 220 circles of registration out of 226 situated in all the districts, and from 58 towns out of 72. The death-rate for the towns averaged 2·0 per 1,000, and for the country circles 0·6 per 1,000. The monthly deaths from bowel complaints are shown in the following abstract :—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	1,972	July	1,729
February	1,601	August	2,033
March	1,392	September	1,886
April	1,288	October	1,740
May	1,448	November	1,688
June	1,378	December	1,673

The most remarkable fact shown by the present year's statistics of bowel complaints is their great fatality in Madras, with 381,926 inhabitants. Among this population the deaths assigned to this cause were 2,047 in number, equal to 5·3 per 1,000, against a previous five years' rate of 6·5 per 1,000. Most of the districts return rates under 1 per 1,000.

21. *Injuries.*—Deaths under this head included the following numbers :—

Suicides, males	718
,, females	896
Wounds and accidents	7,665
Snake-bite and wild beasts	2,302
Total	11,611

22. Deaths registered under "all other causes" numbered 206,807 out of a total registered mortality of 470,700, and of these absolutely no account can be obtained in the present state of the registration.

23. Section VIII. of the report contains the statistics of European and native troops, together with sanitary notes on the stations. We shall discuss part of the detail of this section on other papers, and shall limit our present remarks to the more important features of the year's returns.

After adding increases of strength, and deducting all losses, the strength of European troops on 1st January 1883 was 11,528. The actual average strength would lie between this number and the strength on 1st January 1882, which was 10,521. We shall, however, adopt the ratios given by the Sanitary Commissioner for 1882, which stood as follows:—

Admissions per 1,000		-	-	-	1,069·4
Daily sick	,,	-	-	-	59·3
Total deaths	,,	-	-	-	10·4

The invaliding of 1882 is not given, but from another report we learn that it amounted for all reasons to 24 per 1,000.

The admission-rate was the lowest recorded in 23 years. The daily sick was about the average of the 11 lowest years of the same period, and the death-rate was the lowest on record except that of 1880, which was 9·9 per 1,000, and quite exceptional.

24. There were 11,658 admissions during the year, and 113 deaths. The most fatal disease was enteric fever, from which, according to the report under review, there were 47 admissions and 23 deaths.

Cholera yielded 15 cases and 9 deaths, but 8 cases and 5 deaths took place among troops on the march, and of the remainder two fatal cases took place at Secunderabad, one fatal case at Bellary, and one fatal case at Madras (Rangoon?). Remittent and continued fevers yielded 580 cases and three deaths. Intermittent fever caused 1,301 admissions to hospital.

There was extensive prevalence of hepatitis during the year. No fewer than 400 cases were admitted, of which 19 proved fatal. The chief admission cause of the year was, however, venereal diseases, of which 3,172 cases came under treatment, or 287·8 per 1,000 of the strength. These are the figures given by Dr. Stephens in his statistics. But in the report itself the annual ratio is 257·3 per 1,000, which is the highest ratio on record, affording, as remarked by the Sanitary Commissioner, "humiliating evidence of the inefficacy of police superintendence to prevent the propagation of this "loathsome malady."

25. *European women and children.*—The average strength of women was 834. Including 241 admissions for childbirth, the total admissions were 1,098, or 1,316·5 per 1,000. The deaths were 10, or 11·9 per 1,000. A remarkable feature of the female statistics is the absence of cholera. There was only one non-fatal case of enteric fever. There were six admissions from remittent fever, of which one proved fatal. The entire febrile group yielded only 112 admissions, and this single death. The admission-rate from fevers was 134 per 1,000, or 50 per 1,000 under the soldiers' rate.

European children numbered 1,444. The admissions to hospital were 1,439, or 996·5 per 1,000, and there were 41 deaths, or 28·3 per 1,000. Of these deaths two were caused by cholera, one by continued fever, and 27 by diseases incident to young children, convulsions, diarrhœa, teething, &c.

26. *Native Army.*—The approximate strength of the native army was 28,160, of which 23,795 were accounted for in the medical returns, and it is to this number that the disease statistics refer.

The admission-rate in the native army in 1882 was 866 per 1,000, the daily sick 32·2 per 1,000, and the deaths in hospital 12·4 per 1,000. Out of hospital the deaths were 2·6 per 1,000, making the native death-rate 15 per 1,000.

The invaliding rate was 39 per 1,000. Both the admission and daily sick rates were under those of European troops, but this circumstance is partly accounted for by the fact that the venereal admissions were 22·6 per 1,000, or about one-twelfth part of the ratio among European troops. The chief admission cause in the native army was fever—8,459 admissions and 61 deaths. There were 113 cases of cholera, of which 65 died.

The ratios among European troops contrast very favourably with these, and go to show the results of good sanitary work at the stations. But it must be also borne in mind that the sepoy who feeds himself is never in as good a condition as the European soldier, who is fed by the State.

27. *Sanitary Reports, Military.*—These consist of abstracts of a few lines each of reports received from 32 stations of British and native troops. They are generally satisfactory, apparently, to the reporters, but for practical purposes they are quite without value.

We are told, for example, that the sanitary state of Bellary was fair, and that of Kamptee, like Bellary, presented "no insanitary conditions to which the disease (fever) could be attributed," while, on turning to the statistics, we find that the admission-rate at Bellary was 2,170·8 per 1,000 in 1881, and 1,324·5 in 1882, and at Kamptee it was 1,415 per 1,000 in 1881, and 1,255·7 in 1882. Other similar cases might be given, but, with such facts before us, we cannot but regret that so little progress has been made in estimating the removable disease causes at Madras stations. If the ratios are inevitable results of occupying the stations, of course the only alternative is removing British troops from them.

28. *Health of Jails.*—At the close of 1881 there were 9,657 prisoners remaining in Madras jails. During 1882 there were 16,297 admissions, together 25,954; of these there were—

Liberated	14,152
Transferred	2,708
Transferred beyond sea	198
Escaped	2
Died in hospital	374
Died out of hospital	5
Executed	49

The average strength in all the jails in 1882 was 8,803. The total admissions into hospital were 7,046, the average daily sick about 254, and the deaths 369.

29. The sanitary history of Madras jails presents some points of great interest, which may be noticed, although they have been referred to in previous memoranda. In the years 1863 to 1866 the admission-rates were above 1,300 per 1,000, and the death-rates from above 10 per cent. to above 12½ per cent. Active measures for improving the administrative and sanitary arrangements were introduced, and the admission and death rates gradually fell until in 1871 the admissions were 779·9 per 1,000, and the deaths 17·9 per 1,000. After this year the death-rate rose, and in 1876, the year preceding the famine, it was 42·4 per 1,000, on an admission-rate of 703·6 per 1,000. It appears that in 1876, when the scarcity was commencing, the admissions were of a more severe character, and when the famine actually arrived in 1877 it led to the result shown in the following abstract, which also shows that since that disastrous period the death-rates have been returning to their former level:—

Years.	Ratio per 1,000 Strength.	
	Admissions.	Deaths.
1877	971·3	175·4
1878	944·4	125·4
1879	890·5	55·8
1880	854·0	44·7
1881	742·5	41·4
1882	800·4	41·9

The death-rate, upwards of 4 per cent., is still much too high, and shows that much lost ground has still to be regained.

30. The jail death-rates in 1882 from the chief diseases, as contrasted with the rates for 1865 in the old time, and for the famine year 1877, have stood as follows:—

Years.	Ratio per 1,000 Strength.		
	Cholera.	Dysentery.	Diarrhœa.
1865	80·	12·8	22·7
1877	25·7	32·1	50·1
1882	3·2	5·7	9·8

Cholera is, of course, a very variable factor, and in one year, 1874, the jails escaped its attacks altogether. As usually happens, the death-rates in different jails varied considerably in 1882. In six jails there were no deaths. The lowest registered death-rate was 5·7 per 1,000 in Cuddalore jail In other jails the rates exceeded 5, 6, and 8 per cent., and the highest rate of the year, 16½ per cent., was returned from Trichinopoly central jail. Among the death causes in 1882 may be enumerated fevers, from which about one-third of the year's admissions took place, but out of 2,402 cases there were only six deaths, "bearing out the remark," says the Sanitary Commissioner, "made elsewhere, "that these fevers are very amenable to treatment if only the patients, as in jails, could be made to "submit to it."

From cholera there were 54 admissions and 29 deaths, of which 34 admissions and 23 deaths were furnished by one jail of former evil repute at Coimbatore.

31. This outbreak presented one peculiarity, namely, that the debtors, juveniles, and females who were all near each other in the jail escaped the disease, while the male prisoners alone suffered, and the medical officer, after minute inquiry, could not trace any connexion between this endemic outbreak and cholera anywhere else. His view of the facts is that the outbreak might possibly have arisen from the percolation of polluted water into the wells supplying the male prisoners. It appears to be a fact, any way, that the prisoners who suffered and those who escaped used water from different wells.*

It is possible, nevertheless, that the cases might all have been part of the current epidemic, for Coimbatore district yielded 1,436 deaths, and the town six deaths during the year, and it is no unusual thing for a prevailing epidemic to swoop down and carry off its victims in ways of which no account can be furnished.

* In cases such as this, the suspected water should always be analyzed and the analysis reported.

32. A somewhat similar outbreak occurred in Madras Penitentiary, and as the dates are given in this instance we can obtain a better connected account of the facts than in the Coimbatore case.

Between the 20th November 1881 and the 14th December 1881 99 male prisoners and two females, all transport prisoners, arrived at Madras Penitentiary from 14 jails in different districts of the presidency, that is to say, 101 prisoners were added to the prison population. These prisoners were all carefully inspected and found free from cholera. At the date of their arrival the prison contained 673 males and 32 female prisoners. This prison is situated on the banks of the Coum, and its subsoil water level is 18 inches below the surface, varying according to the level of the foul river, so that on one occasion the medical officer "saw the female hospital flooded to a considerable depth owing to the rising of the Coum." There are, besides, two large overcrowded graveyards in its immediate vicinity. Nevertheless, this prison has experienced remarkable immunity from cholera for years past. We have here the local causes apparently inactive until the prison population has been increased from 705 to 806, but, as occurs in all epidemic outbreaks, there must be something else present to cause the explosion, and this is the epidemic itself.

It so happens that in 1881–82 there was a very distinct cholera epidemic among the 321,926 inhabitants of Madras district, from which the following mortality resulted :—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
1881.		1882.	
October	2	January	153
November	40	February	175
December	81	March	74
		April	20
		May	4

It will be seen that the addition of 101 prisoners to those already in the jail took place during a local epidemic of cholera, from which 549 of the civil population died; and bearing these facts in mind, we shall be better able to understand the prison outbreak.

The local prisoners presented no suspicious case of disease at lock-up hour on 4th January 1882, but at 6 p.m. two prisoners were attacked with cholera, and between the 4th and 13th January there were in all 11 cases and 4 deaths.

Let us see now what occurred among the transports. At 4 p.m. on 3rd January (26 hours before the prison outbreak) 98 of them were embarked on board ship, and three were retained as being too old for deportation. There was no choleraic disease among them; they had a hot meal before starting. But "they got no food next day till 6 p.m." (that is, on the 4th), "when badly cooked rations were served out." On the 5th there were a few cases of diarrhœa, and one man died in the evening. On the 6th there were four choleraic attacks, and one man died on the morning of the 7th, just before entering the port of Vizagapatam. At that time there were six vomiting and purging cases, three of which were collapsed. The sick were landed and camped out, after which two fresh cases were admitted. The total admissions were seven men, of whom six died, and there was no spread of disease in the town.

This case is one of considerable importance, and the whole outbreak was confined to men who were exposed during an epidemic to distinct local and epidemic conditions at Madras. Part of the Madras prisoners were left there and part of the transports were removed by sea, and both groups were attacked with cholera nearly at the same time. The question suggests itself whether either group would have suffered if the transports had not been taken into jail. The rule during epidemics is always to reduce and disperse the population, whether of crowded localities, or of barracks, or of jails, but never to make additions to the populations as long as the epidemic is present.

33. *Municipalities.*—There are 47 municipal towns, besides Madras town, which is reported on separately. Their aggregate population, including Madras, was 1,729,818 at the census of 1881, showing an increase of 116,068 since the previous census of 1871. This census number was 1,613,750, which, in default of census details for 1881, is used in the town statistics.

The general birth-rate was 33·1 per 1,000, and the death-rate 28 per 1,000, both ratios showing improved registration. The death-rate was 3·2 per 1,000 under the previous five years' rate.

The following are the registered death causes in the municipal towns in 1882 :—

Diseases.	Total Deaths.	Deaths per 1,000.
Cholera	3,512	2·1
Small-pox	2,393	1·4
Fevers	9,947	6·1
Bowel complaints	5,076	3·1
Injuries	585	0·3
Other causes	23,784	14·7
Total deaths	45,296	28·0
Total births	53,450	33·1

The population within municipal limits exceeds the population of the towns, so that the total population under municipal administration in 1882 was somewhere about 2,324,000.

Exclusive of Madras town the estimated income for all the other municipalities was Rs. 15,96,920, or Rs. 1·5 per head of the population. The amount set apart for sanitary purposes in the official year 1882–83 was Rs. 495,536, or 31 per cent. of the income. The expenditure under special heads is only given for nine months ending 31st December 1882, and it stood as follows:—

	Rs.
Conservancy	247,781
Improving town sites	26,627
Improving water-supply	16,567
Markets	8,377
Latrines, dust bins, &c.	35,356
Total	354,708

In a previous section we have given the officers in the vaccination service, and we may here introduce a list of officials employed in the 47 municipal towns furnishing this account of expenditure.

Deducting Madras town, we may assume their population at about 1,330,000, and their staff in 1882 stood as follows:—

Inspectors	20
Supervisors	46
Overseers	22
Maistries	52
Peons	166
Sweepers	2,378
Tank watchers	52
Total sanitary staff	3,336

Their material was as follows:—

Carts	870
Dust bins	4,526
Public latrines	362

It cannot be denied that if the conservancy work done corresponded in a reasonable degree to the means provided for doing it, there must have been a large amount of useful current sanitary work carried out in 1882, and it is not unreasonable to conclude that part of the reduction in death-rate, which in 1882 was 3·2 per 1,000 under the previous five years' average, may have been due to this work.

A brief abstract is given of the year's work in each municipality, but there is little in these abstracts calling for remark. Nothing in the nature of permanent sanitary works appears to have been carried out during the year.

Cleansing has been more or less carried on, but it appears to have been chiefly outside work, while, as is well known, the want of conservancy is greatest in compounds and inside houses, including removal of cattle. There is no drainage properly so called; what drainage there is is mostly surface drainage of public thoroughfares, which is chiefly effected by cuts in the soil, without any adequate provision for keeping sewage and rainfall out of the subsoil. The large town of Bellary, with a population of some 50,000, has cesspools, its drainage is unsatisfactory, and its five year's death-rate had exceeded 3½ per cent.

Generally speaking, the water-supply from tanks, wells, and rivers is favourably reported on, and in some cases watchers are appointed to keep people from fouling the supplies.

Taking the year's facts as a whole, they lead to this conclusion, that the chief disease causes in these towns are connected with a polluted condition of the subsoil, due to absorption of liquid sewage. We have discussed the remedies required in our "Suggestions for the sanitary improvement of Indian stations and their vicinity," and to those we must refer for details.

The municipal towns vary in population. Some of them could be dealt with on the principles we have laid down for small municipalities, but for the larger towns water-supply and drainage schemes would, so far as we can judge, afford the only real safeguards from epidemics. In all of them the cardinal improvement required is constant cleansing and removal of all sewage impurities, so as to keep them out of the subsoil, either by hand labour or by engineering, water-supply, and drainage works. It must, however, be acknowledged that, taking the municipal reports as a whole, they show that good work is being done.

34 *Local Fund Circles.*—There are 30 of these circles, and they include a population of 28,812,226, which includes the total rural population of Madras Presidency, besides that of some small towns. The birth-rate is stated at 24·2 per 1,000, and death-rate at 15 per 1,000 probably not half the real death-rate.

The local fund circles contain 47,250 villages, of which only 640 have hitherto been brought under conservancy work. The total income of all the circles, one-third of the land cess, amounted for the year to Rs. 13,41,991, of which 27·9 per cent. was appropriated for sanitary purposes. The actual sanitary allotment was Rs. 3,74,689, and of this the amount expended was Rs. 2,11,192 (21,119*l.* for the sanitary improvement of the whole rural population). Nothing can show more clearly how languidly the work is carried on in these circles than the facts of expenditure. For example, the sum set apart for conservancy was 18,179*l.*, while the sum actually spent was 12,406*l.* Again, one of the most important works insisted on by the Madras Government, the improvement of village sites, had 3,094*l.* set apart for it, no great amount certainly, but the sum actually expended was no more than 1,043*l.* For improving the water-supply a sum of 12,394*l.* was sanctioned, but the amount spent on this cardinal improvement was 4,987*l.* The largest amount spent in proportion to the allotment was 2,287*l.* out of 2,704*l.* set apart for latrines, dust bins, drains, &c. The accounts are, however, only given for nine months, but the proportions of expenditure to allotment do not vary materially from those of the preceding entire year's period. This was an outlay of 28,947*l.* out of an allotment of 37,415*l.* for the official year 1881–82.

The general nature of sanitary work during the year can be learnt from the money spent under the different heads, and there is little in the circle reports calling for remark. We may, however, abstract the following statement of Mr. Price, one of the most zealous workers in India in the public health cause, as showing the great difficulties which have to be encountered at present. Referring to village sanitation he says, "There is no money to speak of, and there is no law by means of which to enforce "anything, but notwithstanding this, district officers are,—if the Sanitary Commissioner sees dirt, and "things that are opposed to all sanitary dicta, and this he always does,—called upon by their superiors "to take measures, &c., or to bring it before their impecunious local boards, or something of this "sort. Of course, officers, if they choose to take the trouble, can by their influence do a good deal, "and where cholera appears the people grow frightened and help them; but something more than "this is wanted, and no appreciable sanitary work can be done until there is a law to help officials to "enforce cleanliness, and one which will allow of funds being raised in villages of any size, in view "to their being kept clean."

It is the keeping clean of villages and the protection of water sources which constitute the real safeguards against epidemics, and not any amount of spasmodic activity, which may lead to positive mischief, by disturbing filth and filth heaps when cholera has appeared. Epidemics of all kinds are nothing more than the penalties of past and possibly forgotten neglects of public and private responsibilities.

35. *General remarks and personal proceedings.*—Under this section, Dr. Furnell gives a general account of the year's sanitary work in a number of districts which includes some points of interest. He states generally "that considerable progress has been made in sanitation in the various "municipalities and small towns under local fund boards. This is more marked in some districts "than in others, and depends much on the interest taken in such matters by presidents and vice-"presidents."

This remark shows distinctly that much may be done by official agency and influence, but the statement which follows refers to other agency. He says, "a public feeling in this matter outside "mere official circles has unquestionably arisen, and in my tours I met many intelligent native "gentlemen giving a considerable portion of their time and energies to municipal matters," and then follows this hopeful statement:—"In some districts, Madura and Bellary for example, sanitary "associations have been started by the inhabitants of towns not quite large enough to claim the "honour of a municipality, and by this agency improvements in drainage, scavenging, water "conservancy, and lighting are being carried out." Movements of this class will likely, in the end, lead to municipal government and sanitary law. In the meantime it may be suggested that similar committees in large villages might be of use.

In one district, Anantapur, the following procedure has been adopted with advantage. The Medical Sanitary Officer inspects part of the town and enters the result, with his recommendations, in a book which is passed on the same day to the executive officer, who at once sees to the carrying out of necessary improvements. Once a month the book is sent to the divisional officer, who enters his remarks and passes it to his President. In the meantime another book is in the same course of use, so that a constant system of inspection is carried out with the result that three towns under it "are the cleanest places I have yet inspected" says the Sanitary Commissioner.

36. In the course of the year Dr. Furnell visited Pondicherry with the view of examining the water supply of this French settlement, which is obtained by artesian wells. This is a favourite source with the French authorities, not only in France, but in Algeria, where these wells are scattered all over the country. The Pondicherry wells afford plenty of water sufficiently pure for all purposes, and the cost is not great—about Rs. 2,000 each. The facts have been fully reported to the Madras Government, and it will be sufficient simply to give the conclusions of the Sanitary Commissioner as follows:—

"We have presented to us a town furnished with what must be considered the most essential "necessary of a tropical city, an ample supply of clean water. There are no less than 14 artesian wells "in the place, some ten of which belong to the public. There is besides a supply of water conducted "from a distance, and laid on with pipes in the city. In every street you see hydrants with stop-"cocks, from which the people draw water." And then we have this statement as a matter of fact about cholera alongside the other fact, that the people do not use, as in most Indian towns, foul subsoil drainage for domestic purposes.

"Cholera, during 1881–82 and commencement of this year (1883), has twice swept past Pondicherry, playing sad havoc in the towns of South Arcot contiguous to the French territory, viz., Cuddalore, Porto Novo, Villupuram, Chidanbaram, Negapatam, &c., and yet has never effected a lodgment in Pondicherry. It has also visited the towns lying on the same littoral, and apparently enjoying the same localistic influences."

We are glad to see that one of these attacked towns, Negapatam, is bestirring itself on the subject of artesian wells, but it must be added that so long ago as 1865 the French practice in Algeria was detailed in the report of the Commission appointed to inquire into causes of improved health in the French army there; so that the use of artesian wells is no new revelation to the Indian authorities.

In conclusion, the chief practical result of the Report under review has been to show how small a relation there is between the ascertained sanitary needs of the vast population of Madras Presidency and the practical steps which have been as yet taken to meet them. What is wanted for the whole Presidency is an active sanitary executive, to turn to account the information which has been obtained by the annual inspections of the Sanitary Commissioner and his assistants. There is nothing specially difficult to be done. But one thing is obvious enough, that if the public health is an object worth caring for, the Executive must take a very different position in the matter than it has yet done. Whilst stating this conclusion, we desire in no degree to undervalue what has been done in the towns, but they contain only a fraction of the population; and it is among these uncared-for outside groups that epidemics have their home.

1st August 1884.

No. 3.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for Bombay for 1882, with Appendix.

This report has been drawn up by Mr. Lumsdaine, the retiring Sanitary Commissioner, and there are bound up with it three reports of inspections made by Deputy-Surgeon General Hewlett, of the cantonments of Nusseerabad, Neemuch, and Mhow, with special reference to the discovery of disease causes at these stations.

There is also another report by Mr. Hewlett on enteric fever among troops serving at Bombay stations, and, as the year's work is very voluminous, it will be better to confine the present Memorandum strictly to Mr. Lumsdaine's Report, and to deal with the others separately.

1. The total area of Bombay Presidency is 123,860 square miles, and the population on the night of the 17th February 1881, amounted to—

Males	8,497,718
Females	7,956,696
Total	16,454,414

giving an average density of population 132·85 per square mile. The most densely populated area is the city of Bombay, which has 35,145·27 inhabitants per square mile. The most sparsely peopled district is Thar and Parkar, which has 15·98 per square mile.

2. The births registered in 1882 were as follows:—

Males	255,927
Females	235,419
Total	491,346

The male birth-rate was 30·12, and the female birth-rate, 29·59. The general rate for 1882 was 29·86 per 1,000 of population.

3. In the same year, the following deaths were registered,—

Males	181,835
Females	161,583
Total	343,418

The death-rate was for males 21·40 per 1,000; for females 20·31 per 1,000, and for the whole population, 20·87 per 1,000.

4. The next abstract gives the statistical data for each district of Bombay.

Districts.	Population, 1881.	Area in Square Miles.	Births per 1,000 1882.	Mean Birth-rate for 9 Years on Population of 1872.	Deaths per 1,000 of Population.	
					1882.	Previous 5 Years.
Khandesh	1,237,231	9,944	36·85	21·18	22·07	24·75

Kaladji	638,493	5,757	35·32	15·32	19·10	36·90
Kanara	421,840	3,911	29·93	28·45	25·61	37·99
Ratnagiri	997,090	3,922	20·68	14·28	14·68	19·79
Kolaba	381,649	1,496	24·05	16·01	12·07	16·73
Bombay City	773,196	22	19·52	21·56	26·16	37·55
Thana	908,548	4,243	28·50	21·45	22·09	28·13
Surat	614,198	1,662	35·55	28·10	22·81	26·02
Broach	326,930	1,453	28·58	15·27	20·35	33·34
Kaira	804,800	1,609	32·85	22·32	22·33	31·87
Panch Mahals	255,478	1,613	26·67	18·28	15·98	27·62
Ahmedabad	856,324	3,821	27·32	19·50	24·20	31·84
Kurrachee	478,588	14,115	20·42	9·40	18·40	16·93
Hyderabad	754,624	9,080	11·62	6·42	14·58	12·56
Thar and Parkar	203,344	12,729	24·89	10·00	17·20	15·05
Shikarpur	852,986	10,001	20·22	6·71	20·82	9·61
Upper Sind Frontier	134,181	1,877	10·51	6·96	9·90	7·86

This district abstract affords a history of registration of births and deaths for 10 years in the case of births, and for six years in the case of deaths, and although we could scarcely accept the figures as accurate, they, nevertheless, show that great pains have been taken with the registration, and that improvement in the results is being attained.

5. The population and death-rates among different classes in Bombay Presidency in 1882 were as follow:—

Classes.	Population on the Census of 1881.	Death-rates per 1,000, 1882.
Mahomedans	3,106,482	17·88
Hindus	13,128,729	21·49
Christians	138,326	18·29
Other classes	80,877	39·17
Total	16,454,414	20·87

This abstract shows that the registration of deaths is very deficient among all classes of the Bombay population, except the last in the list, which is probably nearer the truth than any of the others.

6. In order to complete this sketch of the year's registration work, we may insert the deaths, according to age and sex, together with the death ratios registered in each month of 1882.

Ages.	Death-rates per 1,000 living.	
	Males.	Females.
Under 1 year	179·60	152·14
1 and under 5	34·97	32·07
5 „ 10	7·72	7·59
10 „ 15	5·36	6·39
15 „ 20	8·53	10·84
20 „ 30	11·02	12·33
30 „ 40	14·56	13·19
40 „ 50	22·15	16·28
50 „ 60	34·21	26·54
60 and upwards	56·61	48·40

The next abstract gives the ratio of deaths per 1,000 of the population of Bombay Presidency registered in each month of 1882.

Months.	Deaths per 1,000 of Population.	Months.	Deaths per 1,000 of Population.
nuary - -	1·81	July - - -	1·62
bruary - -	1·67	August - -	1·82
arch - -	1·78	September - -	1·75
pril - -	1·61	October - -	1·81
May - - -	1·72	November - -	1·99
June - - -	1·46	December - -	1·85

We have ventured to give this monthly abstract of deaths because any errors in registration are more likely to be diminished in importance by representing the monthly figures, absolutely returned at the time, in a case where there is no reason to think that errors in registration and report differed materially in different months.

The table may thus be accepted as representing if not the absolute, at least the relative mortality of different months, and there is no mistaking the influence of season on the death-rates represented in this abstract.

7. We shall next give the registered causes of mortality in 1882, together with the disease history of the year. The following were the registered death-causes for the whole Presidency in 1882, classified under the usual heads:—

Death causes.	Total Deaths.	Deaths per 1,000 of Population.
Cholera - - - -	7,904	0·48
Small-pox - - - -	1,630	0·10
Fevers - - - -	243,434	14·80
Bowel complaints - - -	28,353	1·72
Injuries - - - -	5,913	0·36
All other causes - - -	56,164	3·41
All causes - - -	343,418	20·87

This abstract shows how very subordinate a death-cause cholera was in 1882. The greater part of the year's mortality was due to fever, while cholera gave rise to less than a forty-third part of the total deaths.

8. We shall follow our usual course in discussing the disease history of the year, beginning with cholera. In the month of January 1882 cholera deaths were reported from Khandesh and Ahmednagar, in the Northern Deccan, from Satara, in the Southern Deccan, from all the districts in the Konkan, including Bombay city, and from Surat, in Gujarat. In this month 272 cholera deaths were registered. In Konkan the disease was a distinct epidemic outbreak, fading away after March, but with an increase of mortality after July. In the Southern Deccan cholera assumed the epidemic character in April, and retained it for the rest of the year. In the Northern Deccan cholera became epidemic in June, and faded away in November. In Gujarat cholera was irregularly distributed in locality and time, and in Sind there were only three cholera deaths in May. The following abstract gives the monthly attacks and deaths for the Presidency:—

Months.	Cases of Cholera.	Deaths from Cholera.	Months.	Cases of Cholera.	Deaths from Cholera.
January - -	434	272	July - - -	2,040	908
February - -	456	297	August - -	2,582	1,156
March - - -	458	351	September - -	1,305	612
April - - -	1,625	754	October - -	814	362
May - - -	4,114	1,835	November - -	322	146
June - - -	2,413	1,170	December - -	113	41

9. Although cholera deaths were registered in all the divisions, they were reported from 125 circles of registration out of 286 in the Presidency, and, out of 24,431 population groups, the whole 7,904 deaths took place in 804 only. As already stated, the death-rate from cholera was 0·48 per 1,000, the previous five years' ratio having been 1·58 per 1,000. The town death-rate slightly exceeded the district rate of the year. It was 0·50. There are 63 towns in the Presidency, of which 27 yielded the whole town mortality, which amounted to 1,052 cholera deaths.

The epidemic of 1882 was thus irregular in its incidence, both as regards time and locality. It showed no tendency to spread in any definite direction, and it left by far the largest part of the country untouched. It consisted apparently of 804 separate outbreaks, during which about 10 deaths on an average in each attacked group yielded the whole epidemic mortality of the year.

10. Among the population groups may be instanced Bombay itself, with its dense crowded population of nearly three-quarters of a million, which yielded 190 deaths from cholera, or 0·25 per 1,000, just one-half of the average town rate, a result which may be fairly placed to the account of efficient sanitary work done in past years.

11. In a preceding abstract we have placed together the monthly attacks and deaths from cholera. The total reported cases of the epidemic amounted to 16,676 and the deaths to 7,904, or 47·40 per cent. of the attacks; but it is worthy of remark that the higher percentages of deaths to attacks, namely, 62·67, 65·13, and 76·64 per cent., all took place in the three first months of the year at the outbreak of the epidemic, and that, as the severity of the epidemic declined in the last three months of the year, the percentages of deaths fell to 44·47, 45·34, and 36·28. This is what usually takes place during epidemics.

12. Although the cholera death-rate, when taken over the whole population of the province, was only 0·48 per 1,000, this rate does not represent the real ratio among affected groups of population. The 804 affected villages contained a population of 1,341,947. The district deaths, as already stated, were 6,852, and this number would yield a death-rate of about 5 per 1,000 for the country population groups which suffered, or just twenty-fold the death-rate of Bombay City, the population of which is more than a half of that of all the affected villages taken together. We naturally ask the question why measures which have been so beneficial in the capital of the province cannot be applied to all these small population groups?

13. Before concluding this sketch of the history of cholera for 1882, it is necessary, in order to know exactly where we are in coping with the disease, to introduce its previous history, which has been as follows for the 16 years preceding:—

Years.	Cholera.		Years.	Cholera.	
	Total Deaths.	Deaths per 1,000.		Total Deaths.	Deaths per 1,000.
1866 - - -	23,627	1·85	1874 - - -	37	0·01
1867 - - -	5,143	0·32	1875 - - -	47,555	2·93
1868 - - -	6,347	0·50	1876 - - -	32,117	1·98
1869 - - -	52,390	3·77	1877 - - -	57,252	3·54
1870 - - -	2,666	0·20	1878 - - -	46,743	2·89
1871 - - -	5,821	0·41	1879 - - -	6,937	0·43
1872 - - -	15,542	1·03	1880 - - -	684	0·04
1873 - - -	283	0·02	1881 - - -	16,694	1·01

The years 1876–77–78 include that disastrous time when epidemics co-existed with famine and scarcity. But, including these years, the mean cholera death-rate for the whole period was 1·31 per 1,000 against 0·48 per 1,000 in 1882. This shows a very considerable decrease of mortality, especially if we assume that 1882 was one of the years of maximum mortality of which the table shows a recurrence every third year.

14. Facts of the same class for each district given in the following abstract show where the reductions of mortality in 1882 took place.

Districts.	Cholera Death-rates per 1,000.		Districts.	Cholera Death-rates per 1,000.	
	16 Years.	1882.		16 Years.	1882.
Khandesh - -	1·41	0·11	Ratnagiri - -	0·48	0·10
Nasik - - -	1·06	0·38	Kolaba - -	0·36	0·39
Ahmednagar - -	1·86	0·24	Bombay City - -	0·74	0·25
Poona - -	1·54	0·23	Thana - -	1·23	0·85
Sholapur - -	2·06	0·82	Surat - -	1·18	0·01
Satara - -	1·89	2·26	Broach - -	0·89	—
Belgaum - -	2·35	1·54	Kaira - -	0·68	0·33
Dharwar - -	2·34	0·15	Ahmedabad - -	0·79	0·30
Kaladgi - -	2·31	0·85	Thar and Parkar -	0·27	0·01

It will be seen that in all the districts, with two exceptions only, there was a large falling off of epidemic mortality in 1882, notwithstanding the fact already stated that this year was one of the recurring years of high cholera prevalence. The district which suffered most in 1882 was Satara, where there was a distinct local epidemic outburst, from the effects of which 2,406 people, out of a population of 1,062,350, died. Reduced cholera death-rates in 1882 otherwise extend all over the Presidency, and apply to districts which were not the seats of famine; so that, as a matter of fact, cholera appears to be less fatal than it was, although it still covers the whole area of the Presidency.

It is right, at the same time, to state that much good sanitary work has been done in these years, especially in Bombay City and in the other larger groups of population.

15. The relation of epidemic intensity to population is shown in the Satara case as follows:—The proportion of attacked villages to the total villages taken over the whole Presidency was 3·3 per cent., and the deaths averaged about 9·8 per attacked village; while in Satara district 18 per cent. of the villages suffered, and the deaths were a little over 10 per attacked village. The proportion of population groups attacked in Satara was nearly six times the proportion in the Presidency generally, but the local intensity in localities where the disease prevailed was not much greater.

The report of the deputy sanitary commissioner enables us to carry this interesting and important point of cholera history still further, in the case of Valva taluka, which had a population in 1872 of 136,089. In the taluka there are 136 villages, of which 39 were attacked with cholera in 1882. The ratio of attacked villages was not 3·3 per cent., as in the province generally, nor was it 18 per cent. as in the case of Satara district, within which Valva is situated; but the attacked villages in this taluka amounted to no less than 48·67 per cent. of the total number. These 39 attacked villages yielded 1881 cholera attacks and 889 deaths, or nearly 23 per village.

16. The incidence of all epidemics appears to be the same in kind. The first result of the statistical method of inquiry was to afford a general idea of death ratios over entire countries. It was next found that certain administrative areas suffered more than others; and then, that within these areas epidemics were more fatal in some defined spots than in the rest of the area.

The Satara case, and a similar case in Belgaum, are of the same kind; and just as we find in our towns that epidemic deaths are mainly due at any given time to particular streets or courts, so in these Indian villages it may also be predicted that the mortality of a village may be chiefly due to a few houses in it. This consideration brings us back to the question of local predisposition and its causes; and hence the practical conclusion of the whole matter is, that known epidemic or endemic localities are the first that ought to be dealt with in forwarding sanitary work, and that cleansing and wholesome water-supply ought not to be left until cholera has attacked the people, because by that time they have already incurred the penalty of previous neglects.

17. The Sanitary Commissioner has introduced into the cholera section of this Report a considerable amount of local cholera history, including dates of attack and other points, of which a few may be noticed as throwing some light on the year's epidemic history.

First, there is no proof that local outbreaks were other than portions of the general epidemic. There were the usual local opinions that the first case had come from an affected locality, but on inquiry nothing could be made of them. The attacks appeared to have resembled local rainfalls rather than floods of water traversing a country.

Among predisposing local conditions are enumerated sites of villages on river banks, filth, want of drainage, bad water, overcrowding of insanitary houses. Local causes of this class may be illustrated by the following history of an outbreak of cholera in the horwád of Kapadvanj, in Kaira. The town has a population of 14,442, which yielded 139 cholera deaths. "The sanitary condition of the horwád "at this time was as under:—A densely populated area with narrow streets and tall houses of two "or more stories, containing within it about 500 deep-well privies and 100 drinking wells, most of "which are in close proximity to the deep-well privies. As it was the monsoon season, the *moris* "of all the houses were allowed to run out, and thus the streets contained in the centre more or less "stagnant open drains of filthy matter. To this may be added the usual filthy collections of surface "refuse. Such was the sanitary condition of the horwád."

18. By way of contrast to this case, we shall here give the cholera statistics of Bombay city, with its three-quarters of a million of inhabitants, for a period of 34 years.

Years.	Deaths from Cholera.	Years.	Deaths from Cholera.
1848	69	1865	3,887
1849	2,128	1866	339
1850	2,997	1867	121
1851	5,435	1868	227
1852	1,520	1869	754
1853	1,148	1870	386
1854	3,507	1871	263
1855	1,645	1872	190
1856	1,846	1873	92
1857	2,181	1874	19
1858	115	1875	834
1859	1,985	1876	374
1860	1,961	1877	2,510
1861	641	1878	1,165
1862	3,170	1879	323
1863	2,209	1880	39
1864	4,847	1881	529
17 years	37,454	17 years	12,026

The first 17 years' column in this table gives the cholera deaths before sanitary work was begun. There were during this period 37,454 epidemic deaths. During the 17 years in the second column, notwithstanding greater accuracy of registration, the deaths had not increased, but on the contrary had fallen to less than a third. But in this third is included the cholera mortality of the famine years 1877–78, when Bombay became crowded by famine-stricken fugitives from the adjacent districts. The average

of annual deaths during the 34 years was 1,426, while in 1882 the number was 190. During the years in the second column certain very important changes have been in progress in the city. The first and most important of these was the introduction of a thorough systematic cleansing and keeping clean of the whole place. During the same years progress was being made in supplying the population with good water laid on from the Vehar and Tulsi reservoirs by gravitation. This great work is not yet completed, but it is hoped will soon be so, and the main drainage of the city has been making progress. The one work which was well done from the beginning was the cleansing, and without undervaluing the influence unquestionably exercised by better water on the public health, we feel that the main practical lesson taught by the Bombay City experience, and which is applicable at little or no cost to every town and village in the Presidency, is that, the war against cholera must, beyond a doubt, be carried forward by cleansing and keeping clean every village and house compound in the country districts.

19. Cholera in Bombay city in 1882 fell chiefly on the population of Parell village, which "has no "system of drainage. The drainage is either received into cesspools or runs into open channels "which discharge into low lying ground. One portion of the drainage soaks into the ground "of Government House compound, and is so disposed of. The well water used by the attacked "group of population was very impure," and "totally unfit for drinking."

We have in this case an ordinary Indian village outbreak of cholera, under the usual conditions accompanying Indian village attacks, while the great population of the city in contact with it almost escapes, under improved cleansing, better water-supply, and advancing drainage.

20. So far as any account is given of sanitary work among affected groups of population, these measures included collection and removal, for burning at a distance, of surface refuse. But an important distinction is made with regard to accumulations of filth and manure, which were not disturbed, but covered with fresh earth. This is in entire accordance with sound sanitary procedure, which requires in all cities and villages that the current cleansing should be sufficient for every purpose of protection, and that no stirring up of filth should be permitted when cholera is in the place. It has not unfrequently been the practice to cleanse imperfectly, and then, when cholera threatened, to put on an additional staff, to make up for previous neglect, a proceeding always more or less hazardous during epidemics.

These appear to be the chief points requiring notice in the cholera history of 1882.

21. *Small-pox.*—The following abstract shows the annual mortality from small-pox in Bombay Presidency since the year 1872:—

Years.	Deaths from Small-pox.	Years.	Deaths from Small-pox.
1872	26,699	1877	27,869
1873	9,935	1878	4,475
1874	3,903	1879	1,156
1875	3,461	1880	940
1876	11,817	1881	539

It will be observed that small-pox in Bombay shows a tendency to periodical epidemics of considerable intensity, but that the year 1881, even with improving registration, yielded the smallest annual mortality on record. The average annual deaths up to 1880 had been 9,973, or 0·61 per 1,000 of the population; in 1881 the ratio had fallen to 0·03, or about a twentieth part of the preceding nine years' average. The small-pox deaths in 1882 had increased to 1,630, or 0·10 per 1,000 of the census population, but the average was still only a sixth part of that of the same nine years.

22. Small-pox deaths were returned from all the 24 districts, with two exceptions, but only from 95 registration circles out of 286, and the whole year's mortality took place in 357 villages, out of a total of 24,431.

The following monthly deaths bear marks of two epidemics, the latter of which took place chiefly in Poona and Thana districts:—

Months, 1882.	Small-pox Deaths.	Months, 1882.	Small-pox Deaths.
January	41	July	148
February	45	August	98
March	66	September	81
April	107	October	98
May	120	November	201
June	146	December	479

Poona district yielded the highest small-pox death-rate of the year, ·56 per 1,000, and out of 1,172 villages, no fewer than 106 suffered. Of the 1,630 deaths in the whole Presidency, 444 were returned from 22 towns out of 63. The town death-rate, ·21 per 1,000, was more than double the district rate, namely, ·08 per 1,000.

Arranged according to ages, the small-pox deaths were as follow :—

Ages.	Deaths.
Under 1 year	311
1 and under 12	563
Above 12	756
Total	1,630

and these figures bring us to the question of vaccination, which for many years past has occupied a prominent place among public health measures in Bombay.

23. The Report gives fully the departmental history of vaccination, which lies beyond our province, but we abstract a few figures from it, which may in some sense throw light on the death statistics already given.

The staff for the official year 1882–83 stood as follows :—

Deputy Sanitary Commissioners	5
Superintendents of Vaccination	3
Inspectors of Sanitation and Vaccination	51
Assistant Superintendents of Vaccination	5
Clerks and karkuns	28
Vaccinators, candidates	455

The total operations performed by this staff in 1882–83 consisted of—

Vaccinations	792,206
Re-vaccinations	66,505
Total for the official year	858,711

Vaccinations according to age stood as follows :—

Ages.	Vaccinations.	
	Total Number.	Successful.
Under 1 year	485,661	468,594
Between 1 and 5 years	284,141	273,132
All other ages	22,404	20,019
Total of Presidency	792,206	761,745

24. The year's results of the vaccination service may be stated as follows:—

Total births registered	491,346
Successful vaccinations under one year	468,594
Small-pox deaths under one year	311
Total successful vaccinations, all ages	761,745
Total small-pox deaths, all ages	1,630

In contrasting these figures, we must bear in mind the epidemic character of small-pox, as shown in a preceding table, but we must also bear in mind that vaccination work of this class is no new thing in Bombay. It has been carried on year after year, and there appears to be reason for believing that the population is becoming less liable to outbreaks of this disease. One really practical lesson which the Bombay experience teaches is that everywhere the greatest gain from vaccination will be obtained by directing the efforts of the vaccination staff as much as possible to the protection of infants, because not only is infant life saved, but the protection is carried into after life. It follows that it is of much greater importance to vaccinate an infant successfully than it is to delay the operation or to vaccinate an adult.

25. As the remainder of the year's disease history is not connected in the present Report with local disease causes, we shall simply give the statistical results for the year.

Fevers.—Diseases classed under this head were, as usually happens, by far the most important death causes in 1882, although there was a decrease of mortality so registered of 28,949 deaths below the number of the preceding year, and of 6,124 deaths below the mean of the nine years, 1872 to 1880, during which years the fever deaths were as follow, with the addition of 1881 :—

Years.	Fever Deaths.	Years.	Fever Deaths.
1872	206,747	1877	336,865
1873	188,201	1878	357,376
1874	183,717	1879	286,526
1875	219,156	1880	246,779
1876	220,833	1881	272,403

The registered fever deaths in 1882 were 243,454. Fever registration appears to have been defective during the first three years of the series, but from 1875 and onwards the great increase in fever mortality during the famine and scarcity years is strikingly shown, and since then the mortality has declined.

The fever death-rate for the first nine years in the table was 15·38 per 1,000 of the population. In 1881 the rate was 16·56, and in 1882 it was 14·80 per 1,000. During the whole period in the table the chief sufferer has been Ahmedabad district, which, for some reason or other, has registered a fever death-rate for the first nine years in the table of 20·67 per 1,000, which attained to 24·82 per 1,000 in 1881, and was 18·88 in 1882.

In the rural circles the fever death-rate of 1882 was 15·15 per 1,000, and in the towns, all of which suffered more or less, the rate was 12·36 per 1,000.

Fever deaths were returned from all the 286 registration circles, and from 22,302 villages out of 24,431 in the Presidency.

26. The following abstract shows the monthly prevalence of fever mortality in 1882 :—

Months.	Fever Deaths.	Months.	Fever Deaths.
January - -	21,985	July - - -	17,314
February - -	20,236	August - -	19,534
March - - -	21,905	September - -	19,654
April - - -	18,745	October - -	21,648
May - - -	19,088	November - -	25,257
June - - -	15,557	December - -	22,531

So far as concerns the relation of fever mortality to climatic causes, this abstract appears to show that drying up after rain and variable temperatures with cold tend to raise fever mortality, but, as already stated, there are no facts in the Report to show how far climatic causes may have been influenced by local insanitary conditions, especially as regards sources of malaria.

27. *Bowel complaints.*—Deaths registered from bowel complaints have been for the last 10 years as follows:—

Years.	Deaths from Bowel Complaints.	Years.	Deaths from Bowel Complaints.
1872 - - -	33,664	1877 - - -	60,257
1873 - - -	26,249	1878 - - -	41,165
1874 - - -	26,990	1879 - - -	26,349
1875 - - -	33,650	1880 - - -	24,452
1876 - - -	33,683	1881 - - -	30,342

This abstract, like the preceding one, shows a great increase of bowel complaint deaths during the famine period. The death-rate for nine years to population, including the famine years in this abstract, averaged 2·10 per 1,000. In 1881 it was 1·84, and in 1882 it was 1·72 per 1,000. In the latter year 28,353 deaths were attributed to this cause.

The fact that bowel complaint deaths were registered in 271 circles of registration out of 286 shows a very general distribution of them. But out of 24,431 villages the whole mortality was returned from 5,646.

The deaths registered month by month in 1882 were as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January - -	2,128	July - - -	2,652
February - -	2,053	August - -	3,149
March - - -	2,011	September - -	2,916
April - - -	1,936	October - -	2,399
May - - -	2,302	November - -	2,298
June - - -	2,184	December - -	2,330

The average mortality for the rural circles was 1·69 per 1,000, and for the towns, all of which, with two exceptions, returned deaths under this head, the death-rate was 1·96 per 1,000.

28. *Injuries.*—Deaths from injuries during 1882 were as follows :—

Causes.	Deaths.	
	Males.	Females.
Drowning	1,255	1,387
Poisoning	58	45
Hanging	124	90
Wounding	249	112
Wild beasts	53	18
Snake-bites	847	430
Other causes	910	335
	3,496	2,417
Total	5,913	

The mean death-rate from injuries during nine years up to 1880 was 0·40 per 1,000 of the population. In 1881 the rate was 0·36 per 1,000, and it was the same in 1882. We would venture to call attention to two points in the abstract. The first of these is that 2,642 people were drowned, and that other reports have shown that most of these drownings, whether intentional or accidental, have taken place in tanks and wells for supplying domestic water, thus affording an argument for protecting all water sources from accidents of this kind. The other point is the large mortality from snake-bites, and the necessity it shows for greater activity in destroying venomous snakes. The mean annual number of deaths for five years, 1877 to 1881, from this cause, was 1,119, which had risen to 1,277 in 1881.

The following abstract of monthly deaths during 1882 shows the times of most danger to life from snakes, and also the times when there ought to be greater activity in their destruction :—

Months.	Snake-bite Deaths.	Months.	Snake-bite Deaths.
January	35	July	168
February	39	August	188
March	47	September	211
April	63	October	166
May	102	November	71
June	149	December	37

29. *All other causes.*—Deaths from all other causes amounted to 56,164, or 3·41 per 1,000 of the population. We have no information as to the causes of these deaths, but it is worthy of remark that the towns which ought to have the most efficient means of arriving at the truth return these unclassed deaths at 10·51 per 1,000, while for the rural circles the ratio is 2·37 per 1,000. Nevertheless, the high town rate may be due to better diagnosis. The mean annual deaths under *all other causes* for a period of nine years, 1872 to 1880, amounted to 70,935, but this mean included 238,426 deaths due to the great famine year 1877, to which we drew attention at the time, as marking a great deterioration of the public health, apart from the losses due to epidemics.

30. Under the head of *Sanitary Works* (*Military*), it is stated that Rs. 119,036 were spent at 22 stations in Bombay. The details for each station are given, but they require no notice further than that the works done belong to current repairs rather than to sanitary work properly so called; useful, no doubt, but not likely to benefit the general sanitary condition of the stations themselves.

31. *Sanitary Works* (*Civil*).—Under this head are given the population and expenditure of municipal and other towns in the province, arranged under each of the administrative divisions, of which the following abstract contains a summary :—

Division.	Number of Towns.	Population.	Annual Income.	Expenditure on Conservancy.
			Rs.	Rs.
Northern	34	613,908	899,816	213,905
Central	58	624,212	961,308	257,285
Southern	32	312,877	285,491	134,217
Sind	39	323,692	772,318	186,872
Total	163	1,874,689	2,919,433	722,280

These 163 towns, with a population of 1,874,689, and an income in round numbers of 291,943*l.*, spent 72,228*l.* on cleansing, or about 25 per cent. of their income, or about 15*d.* per head. But cleansing is not the only improvement carried out. In many of the towns in all the divisions surface drains have been or are being provided, generally of shallow section and impervious material, but they appear to be mainly laid down in public streets and thoroughfares, while in lanes and bye-ways cuts

in the earth are adopted. The result, of course, is that, while the external appearance of towns drained in this manner is improved, the more unhealthy parts of them are undrained. But, properly speaking, none of the towns are drained except into household cesspits, and wherever there are house wells the water in them is liable to pollution by sewage infiltration.

In a number of towns better water-supply has been provided by public wells, or by bringing in a filtered water-supply by means of reservoirs, filters, and pipes. In some cases water is distributed by means of hydrants in the streets. The important water-supply for Kurrachee was nearly completed. No large works were undertaken during the year, and although a plan for the drainage of Poona and applying the sewage for agriculture has been completed, the present Report gives us this information about it, that "the local distrust is such that nothing has been done."

Most of the towns appear to have proper markets, kept clean. Generally speaking, there has been much good surface work, apparently, done, and more attention is being paid to the surface drainage and water-supply; but the great work of purifying the subsoil by filling up all cesspits and closing house wells near them has yet to be done. These improvements imply either the introduction of permanent works of house and town drainage, or such structural alterations in the house compounds as will admit of the collection and removal of household sewage by hand labour. One instance is mentioned in which refuse water from houses in the bazaar at Kanara "is removed, at the cost of the owners, by means of iron receptacles placed in the rear of the houses, and they are emptied daily." This is one of the best substitutes for house drainage, but, under a proper town drainage system, a few feet of drain pipe to connect the house with the sewer outside would save the cost of the iron receptacle, its wear and tear, and the daily outlay for removal of its contents.

32. It is not easy to estimate what may have been the influence on the public health of this surface work, but if we could rely on the statistics, the results have not been without encouragement. For example, the general death-rate of the towns for five years preceding 1882 had been 35·82 per 1,000, while in 1882 the rate had fallen to 25·93 per 1,000. But on the other hand, there had been a similar reduction in the rural death-rate from 26·73 to 20·13 per 1,000. These country rates are manifestly incorrect, but the better town registration would apparently show a considerable saving of life.

33. *Local Fund Circles.*—These circles, situated in the different collectorates, receive small annual grants for local improvements, chiefly for conservancy and improved water-supply. The amount of work done by them is no doubt useful, but all that can be said about it is that the extent of it falls far short of the necessities. What appears to be wanted for these rural population groups is some executive authority to systematize the work and to render it thoroughly effectual, for it is known that the chief sanitary problems everywhere in India lie, not among municipal towns, but in country villages and within the compounds of their houses. We are glad to learn that steps have been already taken by the Government to deal with villages.

34. We have stated the sanitary improvements for the smaller class of municipal towns and for villages in our Suggestions for the Sanitary Improvement of Indian Stations and their vicinity (revised edition, 1882), and we must refer to these for particulars.

35. Under the head of general remarks are included a separate report by the Sanitary Commissioner on the Ghorpuri lines at Poona, a report on drainage for Poona city, or rather on the present substitutes in use instead of drainage, and an inspection report on Aden, and on water analysis, all of which we shall notice briefly before concluding our remarks on the present year's report.

36. *Ghorpuri lines.*—The case against these lines is tersely stated by the Sanitary Commissioner as follows:—"For some years these lines have been acquiring an increasing notoriety as very hotbeds of "malaria, and of late regiment after regiment has been so reduced in efficiency by admissions into "hospital from paroxysmal fever that abandonment of the site has been talked of."

There are two sets of barracks at Poona, viz., Ghorpuri lines and Wanowrie barracks, about a mile distant from each other, and the relative amount of paroxysmal fever in each set on a 11 years' average has been as follows:—

	Admissions per 1,000.
Ghorpuri - - - - -	652·09
Wanowrie - - - - -	324·85

The relative ratios during these years were—Wanowrie 1 to 2·01 in Ghorpuri.

The present report contains plans and sections of the ground occupied by both sets of lines, which show that the ground slopes between the two sets of lines, so that the barracks at Wanowrie are about 100 feet higher than those at Ghorpuri, but this in a line of above one mile would make no great difference in the drainage of the sites. The subsoil is essentially the same under each set of lines. There is solid trap rock 5 to 6 feet below the surface; over this is a layer of moorum, with a few inches of earth over all. A number of samples of moorum taken close to the barrack blocks showed on chemical analysis the presence of free ammonia, albuminoid ammonia, and chlorine, but the proportions were not notably greater in the moorum at Ghorpuri than in that taken at Wanowrie. Still, it must be admitted that the surface and subsoil to a certain depth showed more or less pollution by organic impurities.

Trial openings made in the ground showed no trace of unusual damp, but still the sites are not drained, and no provision had been made for draining away the used water-supply, which in the Ghorpuri lines amounts to between 17,000 and 18,000 gallons a day.

So far as can be judged of from the barrack plans, there is nothing in them to account for the large excess of malarial fever at Ghorpuri. But there is what appears to be an essential difference in the sites occupied by the two lines. To the windward of Ghorpuri lines during nearly six months there is a great area of wet cultivation, which comes to within 600 yards of the barracks. This area is nearly a mile distant from Wanowrie, and the wind blows over it towards Wanowrie for only 10 or 12 days in the year. The length of this irrigated area, as shown on the map, is about a mile, but its whole breadth is not shown, although the part shown in the map is about half a mile broad. Of all the causes which have been assigned for the Ghorpuri fever, this is the most probable, and it would also account for the prevalence of unwholesome fogs over the site. The new barracks appear to have been echeloned, so as to receive to the greatest advantage the malarial winds coming from this wet culture. It is possible that the local climate might be improved by drainage of the ground under cultivation, by regulating the wet culture, so that no more water should be applied than is absolutely necessary, and by planting a belt of trees between the ground and the barracks.

Since the report was drawn up we believe that the Government of India, as stated in our last year's memorandum, has decided to remove the troops from these lines by way of trial. If on their returning the fever re-appears, there would appear to be no resource left but to abandon the site, unless its unhealthy surroundings can be done away with.

37. *Drainage of Poona city.*—Under this head the Sanitary Commissioner discusses the drainage scheme for Poona proposed by Colonel Ducat, and endorsed by Sir Robert Rawlinson, in relation to certain statements made by the Secretary to the Municipal Committee on the supposed superior advantages of the dry-earth system of conservancy, and its adaptation to the manufacture of poudrette. This discussion, like all others of the kind, has two sides to it, and the question at issue is whether in a city like Poonah, with some 100,000 inhabitants, the dry-earth system is as effectual and economical as against the cost of permanent works as it might be made for a village or a military station. The dry-earth system is not under discussion, but the question is whether the municipal committee is well advised in trusting to it for protecting the health of so large a population.

The Sanitary Commissioner shows in his special report that the dry-earth system provides only for the removal in an imperfect way of most of the house sewage, including a certain amount of liquid which cannot be separated, but that the cleansing is by no means sufficient, while the water brought into the town for use is left to find its way to an outlet. "At present," says the Sanitary Commissioner, "some of this water finds its way into the river, and as liquid refuse it converts the stream "above the old city bridge into a pool of the foulest sewage. The greater portion, however, is "absorbed before it reaches the river, and adds very considerably to the generally polluted condition "of the soil and subsoil. Under a sewerage system all would eventually be changed. The filthy "discharges from bath-rooms and kitchens, and the still filthier ooze from privies would no longer "lie about to taint the air and endanger the water-supply, and the enforced supply of public latrines "and urinals would in time suppress those every-day practices which are as degrading as disgusting." And in the reply to the Secretary's opinion that the existing Poona system is the best, he asks, "Can "that system be 'by far the best' which leaves every day upwards of 100 tons of night-soil to pollute "the banks of the intersecting streams, to lie broadcast here, there, and everywhere, and form "sickening pools of fœtid ooze in side lanes and gutters?" We must accept this official statement as showing the general result here as everywhere else, even in our own home camps, of dealing with one element only in sanitary administration, and leaving all the others to themselves. We desire in no sense to undervalue the effect of thorough cleansing, by any system, on the public health, but it must be thorough. If the municipality chooses to adopt hand collection and hand removal of all town refuse, this must include the waste water, and the total prevention of such results of their present proceedings as the Sanitary Commissioner has described. The point of profit or economy dwelt on by the Secretary to the Committee does not primarily enter into the public health question. The first thing to see to is that the work be thoroughly done, and the second that it be done in the most economical manner. For a population of 100,000, it would be contrary to all experience that this Poona poudrette system should by itself remove all the local disease causes, and then we have the constant experience that removal of town and house sewage is most cheaply and effectually done by house drainage, and hence we must either accept the Poona practice as a remedy, which, in the face of facts stated by the Sanitary Commissioner, we decline to do, or the municipality must be prepared to collect and remove by hand labour all the house sewage not used for poudrette making, so as to abolish entirely the risk of its lying on the surface and draining into the subsoil, or they must adopt a general drainage system which will collect all the house sewage house by house, and convey it innocuously to an outlet, there to be applied for agricultural purposes at a distance.

38. *Report on Aden.*—This Report is mainly an abstract of facts regarding the sanitary condition of the station, but it calls pointed attention to the present and prospective condition of the water-supply and house cesspits. We have dealt with these points on former occasions, and there is little that can be urged on the subject that has not been said before.

Mr. Lumsdaine advises the substitution of drain pipes laid in the present unsatisfactory water channel for conveying water from Sheik Othman wells. This channel is built of bricks and stone slabs, but as it is carried partly across a marsh, and is liable to be submerged, there is every probability that infiltration takes place from without. The proposed remedy of laying earthenware pipes in the channel, with careful filling in with concrete, would prevent any injury to the supply, but, if there be sufficient pressure, small iron pipes would probably answer better. No analysis of the water is given.

The house-drainage question of Aden is one of great importance. At present the whole sewage appears to be passed into the subsoil, and a new settlement is in course of formation on the mainland,

where, unless great care is exercised in its sanitary arrangements, we shall have a plague spot in time. Considering the vast importance of Aden to commerce, and recent outbreaks of cholera there from neglect of very obvious precautions, we feel it incumbent on us to advise, as we have done before, that all cesspits should be cleared out and filled up, and proper conservancy introduced for the collection and removal of all house sewage. It is a somewhat curious comment on our sanitary administration at Aden, that a Frenchman finds it pay him to purchase the burnt surface sweepings, screen them, and export them to France.

39. *Water analysis.*—Under this head are given the results of examinations of three river samples, seven from Tulsi reservoir, and three from Vehar reservoir, Bombay, and 39 well waters. Nine of the samples were taken at Nasik, 31 at Baroda, one at Mount Abu, and the Tulsi and Vehar samples at Bombay. The results of some of the examinations are interesting and important. The Tulsi samples taken from the surface and middle strata of water gave from 4·2 to 7·7 grains of solids per gallon, of which chlorine averaged about one grain only per gallon. One sample taken from the bottom of the lake yielded 11·9 grains of solids, but still the chlorine was only 1·05 grains per gallon. The ammoniacal products increased to a certain extent near the bottom of the lake, but almost disappeared in the distribution pipes. The constitution of the Vehar water was essentially the same. Seeing that both reservoirs are at no great distance from the ocean, the amount of chlorine is not large, and the ammoniacal products are no doubt of vegetable origin, as all the samples showed vegetable débris and infusoria under the microscope. Both waters are otherwise remarkably pure, but the microscopic and analytical results point to the necessity we long since showed to exist for filtering the supply before distribution. Were this done, Bombay would vie with any town in existence in the purity of its water-supply.

The river samples taken from the Godavari, near Nasik, are not so pure as the Bombay water. They contain from 20 to 22 grains of solids, but the chlorine is little more than a grain and a half per gallon. The ammoniacal products are small in amount and apparently of vegetable origin. As this water contains vegetable débris and infusoria it would be improved by filtration.

The well samples for the most part have a very different history. With few exceptions they could only be used with great risk to health, and some of them are quite unfit for any domestic purpose. One sample taken from a well at the old bakery, Baroda, yielded 166·6 grains of solid matter per gallon, of which 39·9 grains were chlorine. With two or three exceptions these wells bear distinct evidence of sewage pollution. There is one sample from Mount Abu which appears to have been as pure as the Bombay supply, but it was taken from a new well, thereby showing the source of impurities in the older well waters.

The argument from this table is irresistably in favour of providing new well supplies and taking steps for protecting the wells from subsoil infiltration in the manner pointed out in our suggestions.

40. In conclusion, the practical sanitary teaching of this Report on Bombay Presidency for 1882 appears to point to the necessity of proceeding rapidly with the improvement of towns and villages,—(first), and before all, in cleansing and keeping clean not only the visible surface, but the house compounds; (second) provision of better water and better protection of the water sources, when obtained, in the manner pointed out in our suggestions; (third) the improvement of drainage of village sites and surface drainage by shallow impervious drains. We have shown this method also in our suggestions, which likewise contain the general principles on which village work should be done; (fourthly) the evidence in the Poona Report shows the necessity of proceeding without delay to carry out an efficient drainage scheme for that city.

Lastly, there is evidence in the present Report that, even making allowance for defective registration, the sanitary work already done, especially in Bombay City, has saved life, and has thus afforded an example of sanitary improvement and its results, which might be attained in their degree in every population group in the Presidency, if it were only determined that this work should henceforth be done.

APPENDIX to REPORT of the SANITARY COMMISSIONER, BOMBAY.

The Sanitary Condition of Nusseerabad, Neemuch, and Mhow.

For a number of years past these three stations have attracted attention on account of their unhealthiness for British troops, and more especially from the prevalence of fatal forms of fever. They have all been examined and reported on, but as there were differences of opinion on some points of their history, Mr. Hewlett was directed by the Government to make a special technical examination of them, the result of which is given in a separate report on each station. The reports are appended to that of the Sanitary Commissioner of Bombay Presidency, and we propose briefly to state their results, beginning with:—

1. NUSSEERABAD.

The fundamental facts bearing on the disease history of Nusseerabad may be stated as follows:—

The strength of troops on a ten years' annual average has been 636.

The 10 years' average admission-rate has been 1,897·5 per 1,000, while for the whole Indian army the rate was 1,474·8 per 1,000.

The 10 years' average death-rate was for Nusseerabad 23·73 per 1,000, and for the whole Indian army 19·34 per 1,000.

Of this death-rate 4·24 per 1,000 was caused by enteric fever at Nusseerabad, against a death-rate for the whole Indian army from the same fever of 2·03 per 1,000.

The death-rate from other fatal fevers (intermittent, remittent, and continued) at Nusseerabad was 2·67 per 1,000, and for the whole Indian army 1·42 per 1,000. Cholera has been less fatal at Nusseerabad than the average for the whole Indian army, in the proportion of 2·04 per 1,000 to 3·22 per 1,000.

Apoplexy, dysentery, diarrhœa, and hepatitis are slightly more fatal at Nusseerabad than in the army generally, but the higher rate at Nusseerabad in times past has been essentially due to fevers, as will be seen from the fact that, if the fever death-rate at this station were no higher than the corresponding rate for the Indian army, the Nusseerabad 10 years' death-rate would have been 20·37 per 1,000 against 19·34 for the whole army, while a death-rate of 1 per 1,000 taken from the Indian army cholera rate would have restored the balance.

2. The Nusseerabad inquiry carried out by Mr. Hewlett had for its object the elucidation of the causes of fever mortality there, and the first important result of his investigation is that during the 10 years ending 1881 there had been 43 admissions and 30 deaths from enteric fever; that of these numbers three admissions and two deaths had taken place among a calculated strength of 141 men in the Artillery, while 41 admissions and 28 deaths had taken place among 481 men of the Infantry, giving for the former arm an admission-rate of 2·13, and for the latter of 8·32 per 1,000. The Artillery death-rate was 1·41 per 1,000, and that of the Infantry 5·8 per 1,000.

3. As regards age. Out of the 30 deaths 20 had taken place under 25 years, and the remaining 10 in years up to 32, beyond which no enteric fever deaths had occurred.

As related to season. No deaths had taken place before April, but out of 30 deaths 22 had taken place during the last four months of these years.

4. We shall next abstract the 10 years fever-rates, 1870–79, together with the monthly temperatures and rainfall, in order to show the relation of monthly climatic elements to the fever statistics.

Months.	Aggregate Fever-rates for Ten Years, 1870–79.				Monthly Mean Temperature.	Monthly Mean Rainfall.
	Enteric Fever.		Other Fevers.			
	Admitted.	Died.	Admitted.	Died.		
					°	Inches.
January	2	1	255	5	58·9	0·5
February	—	—	236	—	70·0	—
March	1	—	251	4	72·1	0·28
April	2	2	311	1	85·3	0·08
May	3	1	366	—	93·8	0·25
June	—	—	318	1	91·7	3·45
July	—	—	388	1	85·4	7·65
August	5	3	368	1	83·6	4·69
September	11	10	365	4	83·8	3·89
October	3	2	391	2	80·6	0·25
November	5	6	542	1	73·8	0·01
December	5	2	225	—	65·4	—
Total	40	27	5,264	17	78·2	21·06

Of the total other fevers in this table, amounting to 5,264 admissions and 17 deaths, it may be stated that 518 admissions and 13 deaths are entered under the designation of remittent and continued fevers, and it follows that out of 44 deaths from fever, 40, or above nine-tenths, were due to the severer types (enteric, remittent, and continued).

The monthly climatic elements show that the first five months the temperature rises rapidly, and attains the very high monthly mean of 93·8°, the maximum of the year, in May, but that during the same five five months the rainfall is so trivial as scarcely to call for notice. The active climatic element is rapid rise in temperature and no doubt considerable temperature range, for the difference between the highest and lowest monthly mean of the year is 34·9°. During these five months there were recorded four deaths from enteric fever and seven deaths from the severer types of remittent and continued fevers. The monsoon bursts out in June, and all the rain likely to influence disease causes falls in June, July, August, and September, the average fall in these months being 19·68 inches out of a total annual fall of 21·06 inches. It was during this monsoon rain that deaths from intermittent fever were registered, four in number in all, and it is during and after the rain that the fever deaths mostly take place, so that while during the first six months of the year 12 fever deaths represented the total 10 years' mortality, the last six months yielded 32 fever deaths, of which 23 were due to enteric fever, four to intermittent, and five to remittent and continued fevers. The monsoon and subsequent drying up of rain was hence attended by 28 deaths from the more severe fever types, or 70 per cent. of these deaths.

The question raised by these facts is whether rainfall and temperature by themselves could by any possibility have occasioned such results, and the answer must be in the negative. There must be some other cause or causes let loose by the rain, and that what is called malaria is one of these is

proved by the great increase of intermittent fever as well as of the severer types after the rains have set in. But as we have no proof that the severer fever types are due to malaria and to nothing else we must endeavour to find the causes elsewhere, if any such exist.

6. As regards topography, the cantonment of Nusseerabad occupies a site between 1,407 and 1,470 feet above the sea. It is situated on an open sandy plain sloping to the south, at a distance of 3½ miles from the nearest point of the Aravalli hills. The country between the cantonment and the hills drains down into a nullah about half a mile to the west, which has been embanked in its course. And similar embankments are used to form irrigation tanks by villages in the neighbourhood. The subsoil consists of micaceous or hornblende schists, which are very likely to retain rain-water in any hollows found in them. The account given of the locality in the Nusseerabad Report by the Royal Commissioners on the sanitary state of the Indian Army is as follows: "The geological structure of "the district belongs chiefly to the metamorphic group of rocks. The substratum consists for the "most part of transition gneiss, reached at a depth of a few inches in many places, while here and "there the bare rock appears. In some situations the soil is many feet in thickness. It is formed "of disintegrated rock, chiefly decomposed felspar (one of its constituents), producing a clay of "considerable fertility and moisture. During the dry season water is found from 10 to 50 or 60 feet "below the surface, according to situation, and, as a general rule, at the same depth in the rainy "season."

These topographical facts would apparently imply that the sub-surface rocky formation is irregular, and contains rocky hollows which are not self-draining, the whole being filled with disintegrated rock to a greater or less depth, and thus forming one of the apparently anomalous cases in which the effects of malaria are produced, where there are no apparently marshy conditions. But, besides this, Mr. Hewlett states that there is a good deal of sub-marshy ground to be found at the south-west of the camp after the rains, and there are several favourite snipe grounds within six or seven miles. It should be stated in connexion with this sub-marshy ground that the wind directions show a very considerable prevalence of winds between west and south during the fever months.

7. We have so frequently discussed the water-supply of Nusseerabad that there is little more to be said about it. The whole question appears to be in a somewhat confused state. An impounding reservoir has been formed between rocky hills, and the whole area is carefully protected from fouling. The water is, moreover, laid on to the cantonment, and is not found to be fit for drinking. On the other hand, the water of a public well belonging to a village, Dilwarra, and exposed to the usual sources of impurity in drawing and transport, is used for drinking after filtration. Why is this so? Mr. Hewlett says that the Danta reservoir water is the better water. Danta samples yielded 20 grains per gallon of total solids, of which 7 grains were chlorine. The free ammonia is ·0132 per million, and the albuminoid ammonia ·32 per million. The water shows copious vegetable *débris* with infusorial life. But the analyst very properly points out that the impurity is all of vegetable origin. The rocks of the gathering ground yield all the chlorides. The Dilwarra well yields 42 grains of solid matter per gallon, of which 6·73 grains are chlorine, while it is by no means clear that in this well the chlorine is also of mineral origin. The ammonia is precisely the same in amount as in the Danta water, and the albuminoid ammonia is 0·7 per million.

The chief objection to the Danta water is its taste when drawn, but as the gathering ground is covered with decaying vegetation, especially with euphorbia bushes, the impurities are, in all probability, due to this cause. We agree with Mr. Hewlett in advising the clearing at once, and periodically, of the surface from these bushes, but if any wholesome low vegetation, such as grass, would grow on the surface, it would afford the best protection from vegetable organic impurities. The water should be carefully filtered before use, and received into covered tanks.

8. The sub-surface configuration, already mentioned, points to a probable source of well water impurity where sewage is allowed to pass into the subsoil, because the porous character of the soil will allow sewage from cesspits, as well as rain, to sink into hollows where such exist in the underlying rocks. This is apparently the case, as there are water samples taken from wells near the station, showing an extraordinary amount of impurities. As much as 70 grains of solids per gallon to upwards of 143 grains per gallon, of which, from 15 to 51 grains per gallon are chlorine, are shown by the analyses in the report. Samples of aerated waters sold to the men are described, in which the contained chlorine amounted to 9½ grains and 20·8 grains per gallon. As a general deduction from the facts, it may be stated that there is little chance of men obtaining water fit to drink outside the limits of the station.

9. There has been considerable diversity of opinion on the question of drainage at Nusseerabad, which may be partly due to the time and place where the surface, after rain, had been observed. Where the underlying rock comes near the surface, the probability is that water would disappear more slowly than if there were an underlying hollow.

One medical officer, for example, says: "The drainage is very imperfect, and not sufficient to carry "off half the water which falls during the monsoon season; consequently, what remains, lodges, and "possibly is injurious to health." Another medical officer states that "the ground in the immediate "vicinity of the barracks is in many places so level as to render thorough surface drainage impracticable . . . . there must be great difficulty in keeping the surface clean during the wet season, more "especially as the surface drains are merely trenches in the ground, and not pucca built." On the other hand, this view is not held by the executive engineer, so far as concerns the sufficiency of surface drainage, but in a letter of his, much additional light is thrown on the whole drainage question, as follows:— "The depth of what may be called soil or earth overlying the natural rock formation, does not "exceed 7 feet anywhere. Over much of the area it is only from 1 foot to 3 feet deep. Of this,

" from 6 inches to 2 feet is composed of drift sand, mixed with clay and vegetable matter; below " this, the soil is that which results from the decomposition of felspathic rocks, and so on, down to " the harder rock. Until rock is reached, the soil may be called more or less porous, and during " continuous rain it does, no doubt, absorb and hold up water as would a sponge. It is quite " possible, I think, that as this upper layer gradually dries up after the rains, damp air may arise; " and if such air, rising from such a soil, is hurtful, the condition may be insanitary."

"The above remarks point, I would suggest, rather to the necessity of some system of subsoil drainage than to a want of surface drainage."

There is no system of house drainage for the barracks. At present the stable drainage sinks into the ground, and the fluid barrack refuse is collected and carried away to be thrown on the surface for trees, &c.

The dry earth system of conservancy is in use.

10. Keeping in mind this official statement as to the site itself, we shall consider it in relation to the barrack accommodation.

It appears that there has been a cantonment on this site since 1818, and there is a map in the report, showing what was the arrangement of building in 1821, and we learn from it that "the " barracks of the European infantry are on the site of the lines formerly occupied by a native " regiment, and the artillery occupy the site of the old artillery lines. . . . . The patcherries " of the European infantry have been built partly across the horse lines of the native cavalry regi- " ment," and partly on the site of old huts.

So that we have at Nusseerabad to deal not only with the special surface and sub-surface topography of the site, but with the additional circumstance that the site is an old one, formerly occupied by native troops, the occupation of which Mr. Hewlett considers to have involved "a mistake of the most fatal nature," which might have been avoided by altering the alignment of buildings, and ploughing up and cultivating the old site. And to these defects of site have to be added another, namely, that in none of the barracks has any provision been made for ensuring a current of air between the ground surface and the barrack floors.

11. In the absence of personal local examination, we must take the facts as they have been presented by this special inquiry, and these appear to include all the main reasons of the special unhealthiness and fever prevalence at this station.

Mr. Hewlett sums up the case in these words: "Looking at the station as a whole, its barracks, " hospitals, the state of the surface and subsoil drainage during and after the rains, its water-supply, " its bazaar, and particularly the time it has existed, whether it is a station to which I should feel " disposed to send troops predisposed to enteric fever, and I am forced to the opinion that, taking all " these points into consideration, it most certainly is not."

12. The bazaar alluded to in this extract presents the features of the station itself in an aggravated degree, and there can be no doubt that the soldier's health will be risked just in proportion to the time he spends in this and similar places. It hence follows that improvements at Nusseerabad must include improvements in drainage, water-supply, cleansing, removal of cattle (there are 4,570 animals kept in the Sadar bazaar), and similar measures among the native population.

13. And then arises the question of station improvement itself, in reference to which we would state as follows:—

(1.) When the site was first chosen the importance of the geological configuration and subsoil to the healthiness of buildings erected over it was unknown. Hence, if the cantonment is to be occupied by European troops in future, the influence of the site itself must be taken as a fixed quantity, which may be modified but not changed.

(2.) The risks inherent in the sub-surface are those resulting from the retention of rainfall or drainage in hollows at no great depth below the surface, which water is shown by the well analyses to be largely contaminated with organic matter, the per-centage of which has a tendency to increase by evaporation.

(3.) These risks would not have been so great as they are if the European lines had been laid out on new ground instead of old occupied ground.

(4.) The old site requires to be subsoil drained, to remove as much of the rainfall as possible to a distance.

(5.) The present practice of throwing foul water over the surface should be discontinued, and a drainage system adopted for conveying away to a safe distance all lavatory and bath water, kitchen water, urine, all horse drainage of European and native lines, and for applying it to agriculture. None of this should on any account be allowed to enter the subsoil.

(6.) The dry-earth system, carefully worked, would answer for latrines, but the question would arise whether the same drains which removed the foul water might not be used for removing the latrine sewage.

(7.) The whole water-supply system needs to be reviewed. If the Danta reservoir gathering ground be cleansed of unwholesome vegetation, and kept clear, it ought, with or without additional surface area, to yield perfectly good water, and this ought to be filtered at the station, and carefully protected thereafter.

(8.) As regards the barracks, if these are to be improved, so as reduce the risk of malaria as far as possible, then their floors must have a free perflation of air between them and the ground. Probably a floor raised above the present one would answer best.

(9.) The proposal in the report to plough up the ground of the station and crop it, would be useful, and the area should be covered with grass, or with other low growing vegetation.

2. Neemuch.

14. We shall abstract the statistical data bearing on the health of European troops at Neemuch from Dr. Stevens' tables, and, as will be seen, the sanitary problems presented by this station differ somewhat from those of Nusseerabad. We shall use the same comparison with the army as a whole, and with the following results.

15. At Neemuch the average strength of European troops during 10 years, 1870–79, was 426, and the 10 years' average admission-rate from all causes was 2,242·5 per 1,000, while in the Indian European army, as a whole, the rate was 1,474·8 per 1,000. The 10 years' average death-rate for Neemuch was 29·11 per 1,000, and for the whole Indian army, 19·34 per 1,000.

Of the very high Neemuch death-rate, no less than 12·91 per 1,000 was due to cholera, showing that Neemuch has in times past been one of the chief cholera stations for European troops. For the whole Indian army the cholera death-rate in the same 10 years was 3·22 per 1,000, or less than a quarter of the Neemuch rate. This station has been infested with fatal fevers also, and has yielded a death-rate of 3·75 from enteric fever, while for the whole army the enteric fever-rate has averaged 2·03 per 1,000. Other fatal fevers have yielded a rate of 2·11 per 1,000 at Neemuch, against 1·42 per 1,000 for the whole army.

The local sanitary problem, so far as fatal epidemic diseases are concerned, may be summed up in the following question:—How happens it that the aggregate death-rate from cholera and fevers at Neemuch has been 18·77 per 1,000, while for the whole European army in India it has been 6·67 per 1,000? The total death-rate at Neemuch exceeds the total death-rate of the whole European Indian army by 9·77 per 1,000, and its cholera and fever-rate exceeds the army rate by 12·10 per 1,000. The death-rate from apoplexy at Neemuch has been 2·35 per 1,000 against 1·52 for the whole army. But the excesses at Neemuch are essentially due to epidemics, and we must now see whether any light is thrown on their causes by Mr. Hewlett's inquiry.

16. The first fact of importance in this investigation is a very remarkable one, and this is the great prevalence of malarial admissions at Neemuch as contrasted with the corresponding facts for the whole Indian army. The facts are as follow:—

Fevers.	Admissions per 1,000.	
	Neemuch.	Army of India.
Intermittent	1,058·0	389·4
Remittent and continued	247·7	162·2
Enteric	5·4	4·6
Total	1,311·1	556·2

Neemuch, as shown by this contrast, is not only an epidemic station, but it is a hotbed of malaria. The facts taken as a whole lead to the conclusion that Neemuch must take a high rank among the unhealthy stations in India, and yet it has been stated that in former times Neemuch was a healthy station, and, as such, was resorted to for change from other stations.

17. We shall next give such elements of climate as may enable us to form some estimate of the influence of local climate on health, and for this purpose we shall select the latest completed year in the tables, viz., 1881, and the ten years' fever admissions, 1870 to 1879.

Months.	Aggregate of Fever Admission, 1870 to 1879.	Temperature Means.			Temperature Extremes.			Humidity, 16 Hours' Mean.	Rainfall.
		Mean Max.	Mean Min.	Mean Range.	Highest Reading.	Lowest Reading.	Absolute Range.		
									Inches.
January	173	78·2	48·5	29·7	88·6	39·7	42·9	28	—
February	105	84·6	56·2	28·4	89·5	49·8	39·7	29	0·59
March	111	88·6	58·5	30·1	99·1	45·5	53·6	23	0·18
April	219	99·2	70·8	28·4	108·3	63·8	44·5	18	—
May	245	106·1	76·8	29·3	118·5	63·7	49·8	17	0·20
June	258	98·4	77·3	21·0	104·6	69·9	34·7	40	3·72
July	289	84·4	73·5	10·9	105·7	71·7	34·0	80	15·87
August	501	83·8	72·7	11·1	86·2	70·5	15·4	74	10·63
September	1,064	86·8	70·9	15·9	93·0	66·6	26·4	61	2·92
October	1,234	90·4	65·3	25·1	93·8	59·6	34·2	34	—
November	885	83·3	58·4	29·9	89·1	45·9	43·2	25	—
December	510	79·2	50·2	28·9	84·8	45·9	38·9	20	0·97

This abstract shows that high temperature by itself, or high temperature ranges with air dryness, do not augment fever prevalence at Neemuch. But an immediate increase of fever attends rain and increase of humidity, where the temperature ranges are not excessive. The great rise in fever admissions accompanies the cessation of rain, and attendant increase of temperature range, and of evaporation.

To this abstract it may be added that the highest solar radiation varied between 148·7° in January, and 174·2° in May. The excess of sun heat over night radiation appears to be about 100° to 120°, according to season. Neemuch is a climate with considerable extremes, and the effect of these extremes on liability to recurrence of fever can scarcely be doubted.

Temperature and humidity are both subject to large oscillations, and seeing that the tabular data are monthly averages, the daily variations must be much greater. Anyway, we cannot alter climate. What the data indicate by way of precaution are, care in clothing and exposure, especially when on night duty, avoiding throwing off garments in the heat, without considering rapid fall in temperature which may be at hand, and regulation of barrack-room ventilation, so as to avoid drafts. The great sun radiation may lead to prevalence of apoplexy, unless the head and spinal column be suitably protected, and alcoholic drinks avoided.

18. The next matter for discussion is the local topography of Neemuch. The cantonment is situated on an area of about half a square mile of surface, the northern end of which is 1,634 feet above sea level, and the southern end about 1,543 feet above the same datum. The underlying rock is trap, covered to various depths by red laterite, with underlying moorum or black cotton soil. The surface around cantonments is undulating, and contains numerous villages. The trap sub-surface appears to be of irregular formation, and holds water at from 6 to 9 feet beneath the surface. In other parts the depth varies from 10 to 40 feet. In some places, after rain, water remains in hollows below the surface level. Mr. Hewlett says that for many miles outside cantonment limits, from south-west to north of the European barracks, "there is an area of depression which, during and "after the rains, is very nearly water-logged and marshy. The black cotton soil, of which it for the "most part consists, is especially retentive of moisture, and the prevailing breeze, during and after "the rains, passes over the ground, and its full force is felt in the barracks."

The plateau itself is well situated for surface drainage, except on the north, but Mr. Hewlett says that, although there are sufficient facilities for storm water flowing away from the surface, "this does "not affect that which is absorbed into the subsoil, which is consequently but slowly drained, a "process which takes many months before the ground level lower than the bottom level of the surface "nala is dry."

Together with this condition of the subsoil must be taken into account the subsoil temperatures and soil moisture, of which a number of measurements are given, with the results that, during the rains, the subsoil contains between 45 to 50 or more grains of moisture per ounce weight, with a sub-soil temperature of from 75° to 90°, according to season.

19. The cantonment plan shows several watercourses at no great distance from the barracks, besides a large artificial tank, 1,400 feet long by 700 feet broad, which has been formed by pounding back the water of two nalas by an embankment. "The earthern dam not being water-tight, consequently "a not inconsiderable amount of leakage takes place, and the soil over a large area below the dam "is, during the monsoon season, marshy, and remains so for months after it, a slow ooze taking place "through the dam."

The distance of this tank is about 2,000 feet from the barracks, but even there, although the water level is 15 feet below the hospital floor, it backwaters the subsoil, and "consequently, prevents its "ready escape, and thus tends to keep the ground near the barracks damp. The ground below the "tank is distinctly a malaria-producing source," and it lies to windward of the lines. We have here, then, elements of climate, topography, and subsoil configuration, all of a malarial character, while the evils have been increased by backwatering, and nothing has been done in the way of drainage works to remedy the natural defects of locality. Moreover, if the tank dam has, in the course of time, become leaky, so as to produce this marshy condition of the ground below it, we should have a not improbable reason for the increased unhealthiness of the station.

20. *Water-supply.*—There are 206 wells in cantonments, of which 27 are in the bazaar, 104 are private property, and 102 are public property. A table is given of the data for 44 of these wells in the military lines, and it may throw some light on the subsoil drainage question to quote two examples from this table.

The Soldiers' garden well.—This well has a depth below the ground surface of 35 feet. In June there is 3 feet of water in this well. Then comes the rain, and next month, July, there are 5½ feet of water. In August, 24½ feet; in September, 28½ feet, which is the maximum depth, and then it falls till next rainy season. It will be observed that, as indicated by the water-level, the subsoil water which was 32 feet below the surface in June had risen to within 6½ feet in September. It need scarcely be pointed out that a rise such as this, experience indicates, must have important consequences on the local climate. Take another case, which appears to show the influence of water-logged subsoil. It is the *Hospital filter well*, from which the troops are supplied. Its depth is 45½ feet below the surface level. In July there are 25 feet of water in it, which would bring the water level to within 20½ feet of the surface. This is the lowest level attained by the water. But in September, under the action of the rains, this well has 43 feet of water, and, as will be seen, the level comes within 2½ feet of the ground surface. As the Leora tank, to which we have referred, has a surface level of about 15 feet below the hospital, it appears not unlikely that it influences the subsoil water level in the well, although at a distance of above 1,800 feet. Generally speaking, the water from wells within the lines is of fair quality, and that from the Hospital filter well contains 34·3 grains of solids per gallon, of which 2·2 are chlorine. The free ammonia is ·002, and the albuminoid ammonia is ·05 parts per million. It contains a little microscopic vegetable debris with monads. Very different, however, is the case with the outside native wells, some of which afford water little better than sewage. To show the risks arising from native carelessness, Mr. Hewlett says that he saw cow-dung

from a Bhisti's bullock among the sand used for filtering the hospital well water. Some analyses of water from this well, which had been carried in mussacks, show that while the total solids and chlorine remained the same, the ammoniacal impurities were greatly increased, and that the water contained large numbers of infusoria, including nematoid worms. There is one well to which Mr. Hewlett calls attention, because it is the only one to which a domed cover has been added, and the water drawn by an iron bucket and chain. It contains the same solid contents as the hospital well, namely, 34·3 grains per gallon, but the chlorine amounts to 1·96 grains only. There is no free ammonia, and the albuminoid ammonia is 0·4 parts per million, with a little débris and a few infusoria. It is the only instance of a well which has been improved in accordance with our Suggestions, except that it has not been cased outside with concrete.

The water-supply is apt to fail in dry years, and any means for keeping up the water level in wells would involve the raising of the subsoil water level of the station. What appears to be really required is the measure proposed by the executive engineer, namely, "a judicious selection of "localities for a few new wells that could be sunk free of the trap to a considerable depth, which "would ensure a fair supply. The water might be raised by steam-power to a permanent reservoir at "a sufficient height to allow of service distribution to upper stories by gravitation;" and we would add, every obstruction to the complete drainage of the station, such as the tank and similar impedi-ments, ought to be removed.

21. *Conservancy.*—Mr. Hewlett states that "the most scrupulous care is taken to preserve cleanliness in every detail." The latrines are well attended to, but some improvement appears to be required in disposing of the sewage, which is apt at present to cause nuisance in certain states of the wind. There is no house drainage, and all waste water from baths, lavatories, cook-houses, &c., has to be removed by hand to a distance.

22. *Barracks.*—Mr. Hewlett states, in regard to the accommodation for troops, as follows:—"The "barracks have been built on what I consider perhaps the worst site in the whole cantonment. . . "In the first place the radical error has been committed of placing them on the very confines "of cantonment limits. The jurisdiction of the officer commanding ceases within a few hundred "yards on the north and west sides, and in the case of Neemuch this error is aggravated, as the "country beyond the limits belongs to a native State where no sanitary measures are enforced, and "where every one of the many villages in the immediate neighbourhood of the cantonment may be "justly described as a centre of disease.

"The country, for miles from the south-west round to north, is an area of depression, consisting "principally of black cotton soil, and this is nearly water-logged during the monsoon, so that when "the rains cease and the water level begins to sink, the temperature being still high, malaria is "generated and the air passing over this extensive area at night becomes cold and chill, and is carried "by the prevailing breeze straight into the barracks. The barracks themselves are not water-tight, "and the men live in rooms with damp walls." There appears to be no current of air passed between the barrack floors and the ground surface.

23. The Sadar bazaar contains 2,085 houses and probably 13,000 or 14,000 inhabitants; much useful work has been done in the way of improving the sanitary state of the bazaar, but, on the other hand, it contained, besides its inhabitants, 2,052 animals.

24. Considering the facts as a whole which Mr. Hewlett has stated, there is little doubt as to the reasons why Neemuch has suffered so much from excessive and increased prevalence of epidemics.

In the first instance, a most unfortunate selection of a site for European troops was made. The local topography and subsoil both show that the site is essentially a fever generating one, both as regards topography and local climate, and that no attempt had been made to lessen its disadvantages in these respects by suitable local drainage works. It is further shown that the local disadvantages have been increased by mistaken measures for increasing the water-supply by the bunding of ravines, whereby the subsoil water-level has been raised and a considerable area of marshy ground added to that already existing.

Mr. Hewlett justly remarks that it is a difficult matter to suggest practicable remedies for the present evils. Probably the least costly, and, at the same time, the most effectual, would be the remedy said to be entertained by the Army Organization Committee, namely, to withdraw British troops from Neemuch, which he says he is sure "would be the best course to adopt." The force is not a large one, and yet if it is to be retained at Neemuch, certain works of a most costly nature, and far beyond the probable local value of the station, would have to be carried out. These are complete drainage of the country, not only in its surface, but in all the localities where water lodges and dries up.

This would include drainage of the cantonment itself, the abolition of the Leora tank and the thorough drainage of its site and vicinity. In short, efficient works would have to be carried out to keep down the subsoil water level and to drain subsoil hollows.

This needful drainage work would necessitate an independent water-supply as proposed by the executive engineer. These are the chief measures indicated as necessary by the disease history of the station, including, of course, improvements in barracks to remove dampness from the walls, and raising the floors, together with house drainage of the barrack blocks and subsidiary buildings. It is not for us to decide whether the place is worth all this trouble and outlay; what we have to do is to point out the remedies required if the station must be held by European troops.

3. Mhow.

25. The cantonment of Mhow is about 2,000 feet above sea level. It covers an area of six square miles and is surrounded by territory, including several unhealthy villages over which there is no cantonment jurisdiction. Its annual occupation by troops on a ten years' average, 1870-79, has been 1,327, Infantry, Artillery, and Cavalry. Within the cantonment, and midway between the European lines on the south and the native lines on the north, lies the bazaar, having a population on the census of 1872 of 17,640, besides 8,602 animals of various kinds which have no stables, but "are tethered inside and outside the houses and all their stale sinks into the ground."

The subsoil consists of a few inches of earth resting on three or four feet of moorum, which is underlaid by rock. The general contour of the ground is formed of ridges sloping down to water-courses, and the natural means of drainage appear to be ample; but ground of this class requires its drainage facilities to be made use of, otherwise water may gather in the subsoil of hollows and generate malaria, and this appears to be the case in several localities near the barracks of European troops. There is a series of interesting diagrams given in the report to show the relation of subsoil damp to the different cavalry barracks, the general result of which is that, during September, water is found at a few feet only below the surface. Similar trial wells might be advantageously dug in many Indian cantonments, and they might enable us to trace the origin of malarial fevers close to or even under the unventilated floors of barrack rooms. In the present case, Mr. Hewlett says that the "ground floors of all the barracks (Cavalry) were found to be more or less damp, especially in the "mess-room of No. 3 barrack, which presented the appearance of having been recently washed down, "although it had not been so for a week previously." These details will be sufficient to illustrate the general question of site, and we shall next state briefly what has been the past disease history of this station.

26. Mhow can scarcely be classed as an epidemic station, and although not altogether what may be called a healthy station, it by no means ranks so low in the scale as other stations in Bombay Presidency. Its death-rate from all causes, on a ten years' average, has been 11·68 per 1,000, a rate which compares very favourably with 19·34 per 1,000, which ruled in the whole Indian European army during the same ten years. Tried by its admission-rate, however, the results have not been so satisfactory. This rate has amounted to 1,695·5, while that of the Indian army has been 1,474·8 per 1,000. Of the total admissions at Mhow, 787·2 per 1,000 have been due to fevers, while for the whole Indian army the fever-rate had been 556·2 per 1,000. It follows that the higher rate at Mhow was due solely to the greater prevalence of fevers. Mhow must therefore be ranked among the Bombay fever stations. But a further analysis of the figures shows that the excess of fever prevalence at Mhow is due solely to intermittent fever, which yielded 701·9 per 1,000 at Mhow, against 389·4 per 1,000 for the whole army. Here again, the admissions from malarial fever at Mhow make up far more than the total excess of admissions at this station over the total admission-rate of the Indian army. As regards the other fevers, remittent and continued fevers have been less prevalent in Mhow than in the army generally, in the ratio 81·8 per 1,000 to 162·2 per 1,000; and enteric fever admissions have been also fewer, the Mhow rate having been 3·5 per 1,000 and the army rate 4·6 per 1,000. While comparing these admission-rates, it is necessary to call attention to the fact that the varying element of venereal disease has no influence in the comparison, because the rate at Mhow, 205 per 1,000, does not differ materially from the army ratio of 203·5 per 1,000. The fever death-rates for Mhow have been, enteric fever 1·96 per 1,000, and for other fevers 1·13 per 1,000. For the army of India the enteric fever death-rate has been 2·03 per 1,000, and other fevers 1·42 per 1,000. The total loss from fevers has thus been 3·09 per 1,000 at Mhow against 3·45 per 1,000 for the army as a whole. As regards one epidemic, cholera, this station has yielded an average death-rate of ·75 per 1,000, or less than a quarter of the cholera mortality of the army, which was 3·22 per 1,000. Dysentery and hepatitis have been also less fatal at Mhow.

It is unnecessary to pursue the disease history further, and what we have to account for and remedy as far as practicable is the amount of intermittent and other fevers at Mhow. But Mr. Hewlett has introduced a series of interesting comparisons, showing the disease prevalence at other Bombay stations, which will be found useful in differentiating the disease causes in each station.

We have at present to deal only with the broad facts of the case.

27. We shall first place, side by side, the temperatures, rainfall, and fever admissions month by month.

Months.	Aggregate Fever Admission, 10 years.	Mean Temperature.	Rainfall.
		°	Inches.
January	382	66·3	0·12
February	355	71·2	0·26
March	398	77·7	0·29
April	487	85·1	0·12
May	543	86·9	0·82
June	448	79·7	3·69
July	575	77·1	6·38
August	1,374	75·7	7·56
September	2,217	76·2	7·11
October	2,074	77·0	1·18
November	1,026	71·8	0·28
December	568	67·9	—

The annual mean temperature in this abstract is 76°, and the monthly mean range is 20·6°. The annual average rainfall is 31·31 inches, but it will be observed that 28·74 inches fall in June, July, August, and September, and that most of the years fever mortality takes place during the monsoon and the drying-up months. There is nothing in the facts differing from what takes place at other stations, and it can scarcely be said that the excess of intermittent fever is primarily due to climate.

28. But, as related to these climatic elements, we have the facts in regard to drainage and subsoil damp already referred to, and Mr. Hewlett sums up the case in the following words:—"In my opinion "the most fruitful source of malaria in Mhow is the marshy and waterlogged condition of the valley "on the south and south-west of the station. This is the source which principally affects the infantry "and artillery, whilst the undrained condition of the ground on each side of the Gumbir river affects "the cavalry." He even proposed that the cavalry should be removed to Ahmednagar for the improvement of their health.

29. Besides these topographical causes of malaria, there are others connected with local domestic customs, such, for instance, as want of house drainage, cesspits, want of adequate methods of draining away lavatory, bath, and cookhouse water, defects which refer not only to the bazaar, but to the different barracks. As we have often pointed out, all water supplied to a cantonment population for domestic purposes is simply an added disease cause unless it be removed after use. And we quite agree with Mr. Hewlett on the general principle that all such water should be carted away, "unless it "can be made to convey itself through an impervious channel to a safe distance from the barracks "and wells."

What appears to be required in the way of drainage is to relieve the subsoil under and around barracks and quarters of the water liable to accumulate in it after the rains. Drainage work should be local apparently, instead of general, and provision should be made at the same time for removing all refuse water by drains. The former measure refers to sites, and, properly considered, it is a necessary preparation always to be done before the site is built on; the latter is really part of the barrack or house. At Mhow, as at other stations, all merely local sources of malaria, such as those described by Mr. Hewlett, should be drained.

30. *Water-supply.*—"The military and civil population at Mhow is entirely dependent on surface "wells for its water-supply, for there is no deep spring in Mhow, and the storm water sinks into the "moorum, and thus finds its way along the surface or into cracks, in the subjacent trap; and when "it is remembered that the gathering ground is thickly populated by a large garrison with its "numerous native followers, animals, &c., and that there is a native population exceeding 22,000 "persons, it must be evident that the filtering medium must become choked with impurities in time, "and some of these must get washed into the wells."

Nobody can doubt who considers these facts, that, to say the least of it, the water-supply of Mhow is of a dangerous character. Some well waters are shown by analysis to be better than others, but it is the method and its uncertainties which are at fault. For example, there are wells which yield about a grain of chlorine, or even less, per gallon, while there are others which yield 10, 12, 17, 20, and 23 grains and upwards per gallon. One bazaar will yield above 27 grains of chlorine per gallon.

We shall not discuss this subject further, as we entirely agree with the authorities that an independent supply is necessary; but it may show the want of interest or of knowledge of the subject if we state that, while money was being saved for this indispensable purpose, the amount, Rs. 1½ lacs, was appropriated, by order of another authority, "for the purpose of making feeder roads."

31. *Conservancy.*—In the absence of house drainage, and the consequent use of cesspits, the cleansing of this large cantonment has to be effected by hand labour. In some details pointed out by Mr. Hewlett the work might be improved.

32. *Barracks.*—The Report contains full details about the barrack construction, together with proposals for improving some of them, but the great defect is the want of ventilation under the floors.

33. *Bazaar.*—We have already noticed some points in the bazaar arrangements for animals. The subject has been discussed in previous Memoranda, and the local authorities appear to be fully alive to the improvements required.

The place is frequented by soldiers, who drink the foul well water, and are exposed to the foul air, and, such being the case, it is not surprising that if a man is attacked with ague it may become developed into a more severe and fatal fever type.

But the real inefficiency cause at Mhow is malaria, partly general and partly local, and the risk of impure water; and the facts, as Mr. Hewlett has put them forward, point to improvements in these matters as the remedies required.

11th August 1884.

No. 4.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for Bengal for 1882.

1. The statistics in this Report are calculated on the census of 1881, which yielded the following results:—

Under Registration.	Population.
45 rural districts	63,639,056
95 towns	2,466,970
Total	66,106,026

But this total only represents the population of areas under registration, which had not yet become co-extensive with the census areas of 1881, for these yielded the following numbers:—

Males	34,220,905
Females	34,601,015
	68,821,920

The population details for Sikkim were wanting, so that the sexes were not separated, and Naga Hills were not under census. The total population of 1881 was 68,829,920, but, as already stated, the ratios are calculated on the smaller number. It is satisfactory at the same time to know that this registering number is increasing.

2. Arranged according to classes, the registering population was as follows. The death and birth rates of each class are added.

Classes.	Population, 1881.	Deaths per 1,000 in 1882.	Births per 1,000 in 1882.
Christians	100,915	14·20	25·00
Hindus	42,896,410	20·48	22·22
Mahomedans	21,361,687	20·71	23·26
Buddhists	79,721	2·88	4·25
Other classes	1,667,293	16·09	11·14
Total	66,106,026	20·41	22·48

Registration of births was conducted in 45 towns only, and even in these towns, with their better registration machinery, the registered birth-rate in 1882 was only 22·48 per 1,000 of population. This birth-rate of 22·48 per 1,000, with the death-rate of 20·41 per 1,000 given above, require no comment, unless it be that both of them show the present state of the registration, and that neither can be accepted as trustworthy facts, or as representing the actual birth and death rates of the province. They are only approximations, and as such must be accepted for the present.

3. The following abstract gives the population, areas, and death-rates of each district in Bengal:—

District.	Population, 1881.	Area in Square Miles.	Death-rates per 1,000.	District.	Population, 1881.	Area in Square Miles.	Death-rates per 1,000.
Nuddea	2,017,847	3,404	39·37	Bhagulpore	1,966,158	4,268	19·40
Burdwan	1,891,823	2,697	35·42	Cuttack	1,738,165	3,517	19·32
Birbhum	794,428	1,756	34·34	Mozufferpore	2,582,060	3,003	19·05
Bankura	1,041,752	2,621	32·21	Lohardaga	1,609,244	12,045	18·11
Moorshedabad	1,226,790	2,144	30·80	Noakholli	820,772	1,641	17·82
Patna	1,756,856	2,079	29·28	Dinagepore	1,514,346	4,118	17·18
Jessore	1,377,249	2,276	29·26	Durbhunga	2,683,447	3,335	16·98
Backergunge	1,900,889	3,649	28·06	Shahabad	1,964,909	4,365	16·55
Rajshahye	1,388,638	2,361	27·82	Manbhum	1,058,228	4,147	16·33
Balasore	945,280	2,066	27·27	Julpaiguri	581,562	2,884	15·34
Hughli	660,813	830	24·78	Singbhum	561,964	4,336	15·21
24-Pergunnahs	1,869,859	2,120	24·07	Howrah	635,381	476	15·09
Bogra	784,758	1,498	24·04	Sarun	2,280,382	2,622	14·85
Khoolna	1,079,948	2,077	23·90	Monghyr	1,969,774	3,931	14·66
Pubna	1,311,728	1,842	23·84	Hazaribagh	1,404,742	7,027	14·60
Purneah	1,848,687	4,956	21·66	Tipperah	1,519,338	2,491	14·16
Poori	888,487	2,473	21·60	Chumparun	1,721,608	3,531	13·90
Maldah	710,448	1,891	20·86	Rungpore	2,097,964	3,486	13·49
Dacca	2,116,350	2,797	20·84	Faridpore	1,631,734	2,247	13·15
Midnapore	2,517,802	5,082	20·66	Sonthal Pergunnahs	1,568,093	5,456	11·05
Chittagong	1,132,341	2,567	20·05	Mymensing	3,051,966	6,287	8·94
Serampore	1,351,955	343	19·59	Darjiling	155,179	1,234	7·01
Gya	2,124,682	4,712	19·49				

The first three or four districts in this list are the only ones in which death registration was carried out in 1882, with even approximate accuracy, and there is every probability that even in these instances the ratios are under the truth. Neither is there any correspondence between the density of population and the registered deaths. But the data show where improvement in the machinery of registration is required, and this, indeed, is their chief utility. There are no means of obtaining the birth-rates for these districts. The general rate of 22·48 per 1,000 is obtained, in the only available way, by striking an average of the rates registered in 45 towns situated in 30 districts. We must make the best use we can of such district data as we possess, in the hope that future years may yield more accurate results.

4. Divided between the rural and urban populations the death-rates of 1882, compared with those of the previous five years, were as follow:—

	Population, 1881.	Deaths per 1,000.	
		1882.	Previous 5 Years.
45 districts	63,639,056	20·00	15·37
95 towns	2,466,970	31·05	30·63
Registering population	66,106,026	20·41	15·94

These data simply show that the registration of deaths has been undergoing improvement. The town death-rates differ from each other to as great a degree as do the country rates. But generally they bear marks of better registration. Only 13 of them return death-rates under 20 per 1,000, and from this ratio the returns gradually rise to 30, 40, 50, per 1,000. The highest rate of the year, 57·26 per 1,000, was returned from Puri, against a preceding five years' average of 62·04 per 1,000. The following instances may be quoted as showing curious irregularities in registration:—

Towns.	Population.	Deaths, 1882, per 1,000.	Deaths, previous 5 years, per 1,000.
Sitamurhi	6,125	29·38	84·01
Sudharam	5,124	15·61	80·75
Boidobatti	14,718	24·45	79·18

The only remedies for these discrepancies are time and experience. The authorities are quite aware of the bearing of these facts on the sanitary problems in Bengal, and continuous efforts have been made to improve the registration; it is necessary, however, that we should draw attention to them, because of their practical bearing on administrative matters, and also because there has been apparently less progress made in Bengal than in certain other provinces in this important branch of public health work. Under these circumstances it is not necessary to discuss the general vital statistics further.

5. The following were the deaths and death ratios registered in 1882 under the usual heads:—

Diseases.	District Mortality. Population, 63,639,056.		Town Mortality. Population, 2,466,970.		Mortality of Province. Population, 66,106,026.	
	Total Deaths.	Deaths per 1,000.	Total Deaths.	Deaths per 1,000.	Total Deaths.	Deaths per 1,000.
Cholera	170,522	2·67	11,830	4·79	182,352	2·75
Small-pox	12,798	·20	853	·34	13,651	·20
Fevers	891,151	14·00	38,792	15·72	929,943	14·06
Bowel complaints	51,662	·81	9,700	3.93	61,362	·92
Injuries	20,660	·32	951	·38	21,611	·32
All other causes	126,257	1·98	14,475	5·86	140,732	2·11
All causes	1,273,050	20·00	76,601	31·05	1,349,651	20·41

It will be observed that the town mortality in this abstract greatly exceeds the district mortality under all the registration headings, but this result is most probably due to better municipal registration. It is further not unlikely that detailed examination would show that many towns were, on the whole, in a better state under administrative improvements of recent years than are most country districts and villages, and the low registered death-rates in these latter centres of population would thus again point to deficiency of registration. We shall state briefly the results of the present year's report, under each of these heads.

6. *Cholera.*—The year 1882 was one of the great epidemic years in Bengal, as will be seen from the following abstract of cholera mortality given by the Sanitary Commissioner:—

Years.	Deaths from Cholera.	
	Total.	Ratio per 1,000.
1872	37,536	·56
1873	58,673	·88
1874	56,876	·86
1875	108,262	1·63
1876	196,590	2·97
1877	155,305	2·34
1878	95,192	1·43
1879	136,363	2·06
1880	39,648	·59
1881	79,189	1·19
1882	182,352	2·75

There are no other facts which would enable us to solve the questions presented by this table, and they must be recorded just as they stand, in the hope that in time we may be able to account in some sense for them.

7. Deaths from cholera were registered in 609 circles of registration out of 641 in the districts. No part of Bengal escaped the epidemic of 1882, and it attacked an unusually large number of villages (no fewer than 27,314 out of 201,989, or above 13 per cent.), and the deaths averaged between six and seven per village.

8. The next abstract gives the monthly prevalence of cholera in Bengal for a series of years in connexion with the monthly rainfall for 1882:—

Months.	Average Cholera Deaths, 1877 to 1881.	Cholera Deaths, 1881.	Cholera Deaths, 1882.	Rainfall, 1882.	Average Rainfall of previous Years.
				Inches.	Inches.
January	12,299	3,999	8,947	·09	·49
February	6,744	2,616	7,589	·78	·88
March	8,849	2,119	15,692	·30	1·00
April	14,875	13,434	25,587	1·07	1·51
May	11,433	10,833	27,544	5·13	4·09
June	10,121	5,324	22,358	9·24	10·22
July	8,944	6,758	18,135	10·65	13·72
August	6,858	7,155	12,917	12·50	13·26
September	3,322	2,499	5,684	9·23	9·93
October	2,773	2,712	6,756	8·81	4·98
November	5,598	3,674	12,357	1·16	·64
December	9,364	3,753	18,714	·04	·20
Totals	101,135	79,180	182,352	57·66	60·99

The facts presented in this abstract are interesting, for they show,—1st, that cholera is epidemic in Bengal throughout the year; 2nd, that it has two periods of increase, the first including November, December, and passing onwards to January of the succeeding year, the second, March, April, May, June, and July; 3rd, February, September, and October are the months of lowest cholera mortality; 4th, that the cholera of any one year is only a year's event taking place in the general epidemic history of the province, which is a connected current history, and includes the apparent passing over of cholera death-rates from the end of one year to the beginning of the next year; 5th, that increase of cholera mortality co-exists with little rain, and declines when the rains have fairly set in; that the very high cholera death-rate of 1882 co-existed with a diminution of 3·33 inches of rain in that year below the average, nearly the whole of which took place during the months of maximum prevalence of cholera. From another table in the Report we learn that the mean temperature of 1882 differed only fractionally from the average, so that so far as climate is concerned, rise in cholera mortality co-existed with diminution of rain when it was most needed.

9. The mortality from this epidemic varied greatly in different districts of Bengal, and there was little apparent relation of intensity between the cholera of 1882 and that of preceding years in the same districts. In 10 districts the cholera death-rate of 1882 was under 1 per 1,000. In 10 districts it lay between 1 and 2 per 1,000; in other 10 districts it was between 2 and 3 per 1,000; in seven districts it was between 3 and 4 per 1,000; in six districts between 4 and 5 per 1,000. The highest rates of the year were 5·46 per 1,000 in Nuddea, 8·05 per 1,000 in Jessore, 6·24 per 1,000 in Balasore, and in the suburbs of Calcutta, outside the limits of municipal sanitary works, there died 2,476 inhabitants out of 251,438, or 9·82 per 1,000. This great mortality was, properly speaking, attained in an urban population whose cholera death-rate for the preceding five years had been as high as 7·27 per 1,000, the highest of any population group for the period. Of the 95 towns three

only escaped cholera. In very few of them was the death-rate under 1 per 1,000. In the majority, the rates exceeded 2, 3, and 4 per 1,000, and some yielded much higher death-rates than even these. Rates above 10 per 1,000 were returned from the following towns:—

Towns.	Death-rates per 1,000.
Serajgunge	10·31
Serampore	10·83
Faridpore	12·47
Poori	13·33
Meherpore	13·78

Part of these higher rates may have been due to greater accuracy in the registration. This part of cholera history may be briefly summed up as follows:—

Total registering population	66,196,626
Total population groups	201,989
Total cholera deaths, 1882	182,352
Population groups yielding these deaths	27,314
Cholera death-rate per 1,000 for total population	2·75
For previous five years per 1,000	1·52

10. We have no means of arriving at the population of attacked villages, but if it represented the same ratio as existed between attacked and unattacked groups, we should have to multiply the death-rate by about seven to represent the death-rate of the population which suffered.

In January a few districts returned no cholera deaths, but some of these were attacked in February, and others in March; April and May saw the epidemic pretty generally diffused over the Presidency, but although some of the districts escaped in January and February, cholera appeared in all the divisions of Bengal in January. There was no appearance of movement in the epidemic itself, for it covered its ground at the commencement of the year. There was, however, an appearance of movement in the death ratios, which yielded higher rates in the delta divisions at earlier periods than was the case in the North-Western areas. The same facts presented themselves in the North-Western Provinces, where the maximum death-rates moved like waves from the borders of Bengal to those of the Punjab, although cholera may have existed previously more or less over the entire area.

11. The law of cholera in the north of India appears to be as follows:—

(*a.*) General diffusion of cholera of low intensity.
(*b.*) Increase of intensity in the delta regions (Dr. Bryden's endemic area) as the season advances.
(*c.*) Movement of the maximum mortality from the delta districts towards the North-Western districts of Bengal, and from them onwards into the North-Western Provinces and Oudh.
(*d.*) The amount and movement of cholera mortality is related to climatic causes, chiefly to rain-fall; and,
(*e.*) As we shall see further on, the same amount of rain which lowers the cholera death-rate increases the amount of loss from fever.

12. The experience of 1882 shows, like that of all previous years, how little we know of the action of climatic causes on the prevalence of cholera, and how wholly these are beyond our control. We have no reason, however, to suppose that the action of climate is other than secondary. There is no proof that climatic causes will produce or increase cholera by their direct action, but we do know that there are secondary causes which may be either increased or lessened in their activity by the amount of rain, and it is with the secondary causes alone that we can in any measure cope by sanitary precautions. It has never been asserted that cholera was produced by such causes, although, from the manner in which they are dealt with in the following paragraph, it would appear as if the view still existed in India. In paragraph 47 the Sanitary Commissioner states the results of the year's reports in the following words:—"The reports of the year do not cast any new light on "the etiology of the disease. Polluted sources of drinking supply are always more or less suspected, "and local sanitary conditions are very generally indicated as exciting or predisposing causes; but it "is also to be remarked that in several instances local incidence of the disease is quite independent "of local conditions. Climatic insalubrity, deficient rainfall, imperfect drainage, the retention of "moisture and damp in the soil, errors of diet, infection, importation, &c., are all in their turn "accused of favouring, if not absolutely originating, the disease."

The chief defect in this statement is, that the reports summarized do not appear to have given the details of the several instances "where local incidence of the disease is often quite independent of local conditions." Such information, if technically accurate and not mere opinion, would have been of great value. It has never been denied that the epidemic influence of cholera may in itself be so intense as to kill every one exposed to it. For instance, all the cases which now assume the character of ordinary diarrhœa might on this supposition pass directly into collapse and death. So that while in one set of cases the local defects might co-exist with diarrhœa only, of which the vast proportion might recover, in the other set all might die while the local causes remained the same. What is called an "epidemic," whatever the disease may be, varies in intensity, and the relation of local insanitary conditions to the mortality from epidemics is, in the present state of our knowledge, simply a matter of observation and experience, and here we have quite sufficient facts in India alone on which to found consistent schemes of local sanitary improvement with the certain expectation of beneficial results.

13. Here, for example, is one of the earliest of the paragraphs about cholera in the Report under review :—"With the exception of a few insignificant outbreaks of cholera which occurred at the fairs "held at Turkessar in Hughli, Manda in Rajshahye, Faridpur in Pubna, Baroni in Dacca, Sing- "hessur in Bhagulpore, Caragolah in Purneah, and Hurwa and Gunga Saugor in the 24-Pergannahs "(in the latter of which fairs the largest number, 15 cases, took place), all the other fairs, large "and small, were exempt from this disease. This is a very remarkable observation, and, con- "sidering that cholera was rampant all over the province in an unusually severe manner at the "time the fairs were held, this immunity speaks well for the care and attention bestowed in adopting "sanitary precautions against its inroads."

Now, suppose the villages had been as well attended to in their sanitary arrangements as the fairs appear to have been, what result should we have been justified in expecting? And does this experience not prove anew that, under improved sanitary conditions at fairs, the villagers present at them are safer from attacks of cholera than they would be at home, although in former times fairs and their accompanying filth, bad water, and overcrowding were the foci of local epidemic outbreaks of cholera.

14. We shall abstract from the Report a few illustrations of those local conditions under which cholera prevailed; the first shows that unwholesome trades conducted without proper care may be exciting causes of this disease in India as elsewhere.

Cholera prevailed epidemically at a village in Bankura town, which was in a bad sanitary condition. It contains several lac factories, "the refuse water of which is allowed to stand and decompose in shallow ditches." An outbreak occurred in Mijia, which was attributed to pilgrims, but "the magistrate justly condemns the prevailing practice in this locality of heaping cowdung, house sweepings, &c., till they become fit for manure" in open pits, and he advises the adoption of a safer practice in use in India of pitting the manure in ricefields immediately after the crops are harvested. We concur with the Sanitary Commissioner in the opinion that the effect of this method should be further considered with a view to legislation. Many similar important disease causes might be abated by equally simple expedients.

In Soori cholera prevailed from January to September, and out of 1,908 villages 266 yielded 2,264 deaths. Soori town yielded 12 of these deaths only, and they are said all to have occurred within 100 yards of a locality near the Serai, where a traveller suffering from vomiting and purging sought shelter three or four days before. Several people in a house opposite, "who drew their water from a well near the Serai," were attacked, but "when the use of the water was prohibited, only one or two cases occurred within a week's interval." Perhaps the traveller was attacked because he used this same water; but it will be seen that such is not the inference suggested. The town cholera was really part of the district cholera.

In Rampurhat, in the same district, 50 villages out of 1,180 were attacked, and 329 cholera deaths were registered among them. The magistrate considers that an extension of medical relief is required to meet such events, "but," says the Sanitary Commissioner, "while this demand is made "on the medical establishment after the disease has succeeded in gaining a hold upon the people, "what are we to say of the habits of these people when the civil surgeon can write that water for "drinking and other domestic purposes is generally drawn from wells in private compounds, which, "'for the sake of convenience, are built near the privy,' and the adjoining site selected for washing "cooking utensils, depositing of various descriptions of house refuse, and for habitual urination by "all the members of the family?" There is, in our view, no doubt as to the practical accuracy of this view of the case. In a country like India, which suffers enormous losses year after year from epidemic illness as well as from deaths, it is practically impossible to cover the ground with medical aid and appliances. What can be done, however, if it is properly set about, is the prevention, or at all events the reduction of these losses by sanitary measures which in their nature are neither difficult of execution nor costly, and for which the agency is at hand in the villages themselves, if it be only properly organised and directed, as appears to have been the case at the fairs.

In a locality in Midnapore district cholera is seldom absent, and the cause is supposed by the people to be in the saliferous nature of the soil. "The drinking water in these cholera tracts is bad, and the deputy magistrate is disposed to attribute to it the originating cause of cholera."

In Hughli districts 188 villages out of 1,951 suffered from the epidemic, and 644 people died. In the village of Champdani, which was crowded with coolies from the neighbouring jute mills, the disease prevailed epidemically. "Here no sanitary precautions of any kind appear to have existed. ". . . The magistrate considers the sanitary condition of the villages in the district to be bad "in the extreme. Amongst this, the densest population existing in any portion of the globe, there "are as a rule neither privies nor latrines."

Here is a case close to the capital of India. Why can it not be laid hold on at once, and the whole affair put an end to, at the cost of the people who collect labourers for their own profit, and leave them under such conditions?

In Serampore the mortality was "very severe, aggravated as it was by a very fatal outbreak among the coolies of the Wellington jute mills in Rishra," where the sanitary defects, it may be predicted, did not differ greatly from those mentioned above.

Cholera was very fatal in several parts of the Presidency division. It prevailed extensively and fatally in the suburbs of Calcutta outside municipal limits and in certain portions of them, of which it is said: "These bustis are the most unhealthy of all, and the inhabitants filthy beyond conception. "The surface drainage is everywhere obstructed, and what drains there are are full of black oozy "mud, almost entirely composed of sewage, fermenting in the sun and emitting at all times a "sickening and unendurable steneh." Drinking water properly so called is unattainable, tanks

are contaminated in every possible way. During the jute season crowding in temporary huts without conservancy exists. Other localities which suffered much from cholera are densely populated, houses crowded, and open drains and cesspools, ponds, and hollows, containing thick and greenish liquid, exist.

In Jessore, the Civil Surgeon of Majura subdivision attributes "the invasion of the disease to "the insanitary condition of the villages, to the use of polluted water, and perhaps in a less degree "to eating insufficiently matured rice. . . . The magistrate does not coincide in these opinions, "and somewhat glibly remarks that these are mere guesses of no value, as medical science knows "absolutely nothing about the cause of cholera, and as little about the cure of it." It may be suggested in passing that the magistrate himself has mistaken the question at issue, which is neither the "cause" nor the "cure" of cholera, but the determining conditions of local outbreaks which are matters of long observation and experience. He may do great good without knowing the cause or the cure of cholera by simply improving the sanitary condition of his villages, without mixing up this practical point with purely medical discussions.

15. By way of encouraging improvements in this direction, we may cite the experience of Beauleah town in Rajshahye, of which it is stated that "the civil surgeon, with much reason, "attributes the great immunity from cholera which Beauleah town enjoyed this year in com-"parison with the preceding one, during which the death-rate was as high as 8·28 per 1,000, to "the town having had its tanks and filthy pits thoroughly scoured out by two successive inunda-"tions of the Ganges, and to the introduction by the municipality of better conservancy arrange-"ments and a cleaner water-supply." In this town the cholera death-rate in 1882 was 2·07 per 1,000, instead of 8·28 in the preceding year, while Rajshahye district itself had a five years' average death-rate of 1·14 per 1,000, which was raised by the intense epidemic of 1882 to 2·08 per 1,000, not far short of double the average, although slightly under the rate of 1881, which was 2·48 per 1,000.

16. An instance of an imported cholera case is given which, if it were true, would be in contrast to the experience already stated. In Rungpore a case was imported by rail from Eastern Bengal. "The case," the civil surgeon says, "was quickly brought to my notice, and the discharges were "completely disposed of, no other case occurred in the town. Had this man's discharges been "allowed to pollute the ground and thence to drain into a neighbouring well, or his clothes been "washed in the public tank, we should have had, as is too often the case, a fatal outburst among the "population." This statement of the case is not quite accurate, because the table shows that there was another case in the town, so that cholera was there apart from the imported case. In Rungpore district itself, cholera deaths were registered in 16 out of 17 registration circles, and in 204 villages out of 4,206, and besides all this, it has yet to be shown that cholera excreta are more likely to produce outbursts of cholera than non-choleraic excreta. On this point we have not been able to obtain any proof, but rather proof in the contrary direction. The truth of the matter probably lies in this, that filth of all kinds, if in a state of putrescence, is dangerous, but that there is nothing of a specific nature in the results of putrescence to occasion cholera any more than any other disease. We have noticed this case, because of its logical bearing on sanitary precautions against cholera. It only remains to be stated that cholera existed in Rungpore district during every month of 1882, a fact which is itself destructive of the excretal theory. We have nothing to say against the measures adopted in this special case, only they ought to have been extended to all filth in the district, and before cholera appeared.

17. The cholera outbreak in Dacca town presents a few points of interest. The well-water of Dacca, as is clearly shown in a separate report by the civil surgeon, is quite unfit for drinking and culinary use, and the town has lately been supplied with better water, but this has not yet been distributed to the whole population. At the time cholera appeared the country was under water, and according to previous experience there ought to have been little or no cholera on this account; nevertheless, the district had a death-rate of 2·76 per 1,000, and the town of 6·57 per 1,000. Flooding of surface is, therefore, not necessarily a safeguard against cholera under all epidemic conditions, and in Dacca town cholera was fatal even with better water. The history, however, as given by the Sanitary Commissioner, clears up the case. The improved water-supply was introduced in May 1878, and the following annual cholera deaths will show its relation to cholera mortality:—

Years.	Deaths.	Years.	Deaths.
1875	194	1879	118
1876	205	1880	15
1877	289	1881	85
1878	167	1882	527

These data show an apparent relation between better water and lower cholera death-rates, but as a fact the better water is used by about a third only of the population, and the increased death-rates of the last two years have led to "a tendency to discredit the value of the hydrant water." This result is simply a consequence of one-sided views about the influence of water on health, and if it were a necessary consequence it would show that impure water was not so great an evil to the public health as had been supposed, and moreover, that the expenditure on the purer supply had been unnecessary. But besides extended distribution of the supply to the whole population, other

measures of protection from cholera are necessary, as will be seen from the following facts:—"The "disease in epidemic form broke out on the 15th July among some 40 coolies living in two filthy "huts, calculated to hold only 25 men, situated in the middle of the town, not far from the "kutcherries, the inmates sleeping on a damp floor, hardly raised above the level of the ground, "and drinking from a well which was manifestly impure." . . . . "The magistrate and the "vice-chairman attribute this outbreak to impure water, to the insanitary condition of privies, and "to the large 'gors' (cesspits) which are used as general receptacles for the contents of privies and "filth generally."

This statement points directly to practical measures, and these are, supplying hydrant water all over the town, and filling up all wells, abolishing all cesspits, privies, and places of deposit of filth within the town, and providing for the collection, removal, and disposal beyond the limits of the town and suburbs of all filth and impurities by an improved conservancy system. These measures, and not better water alone, are required to meet the facts of the case.

But, nevertheless, the extension of cholera in Dacca is brought under an extension of a home theory that epidemic diseases are spread by milk because the goalas, who supply the town with milk, suffered from cholera, and diluted their milk with foul water. This points to getting rid of the goalas and their belongings as the real preventive of cholera. Any way they should be brought under the same sweeping sanitary improvements as are required for the town.

18. Similar remarks are applicable to the Chittagong report. The cholera death-rate in this district was 2·41 per 1,000, and in Chittagong town, the bad sanitary state of which is well known, it was 2·84 per 1,000. This death-rate appears to have been considered satisfactory, and was, in the estimation of people on the spot, arrived at by the following method. The locality "was surrounded, "bonfires made in every direction amongst these houses, and sulphur sprinkled on the fires, all the "bedding and the clothes soiled by cholera dejecta, which could be got hold of, were burnt. The "soil where contaminated by discharges was scraped up, and fires lighted over it, and thus by timely "measures the conflagration was localized and eventually stamped out." It will be observed that these proceedings, which were attended by a larger death-rate than that of the district generally, were founded on a theory about cholera, and their practical result will probably be to leave the bad sanitary state of this town just where it is. What requires to be done for Chittagong lies in another direction altogether. Bonfires and burning sulphur will neither drain the town and its vicinity, nor fill up foul ditches and tanks, nor will they improve the water-supply or the conservancy arrangements.

19. Gya town had a death-rate from cholera of 9·30 per 1,000. "The disease was almost solely "confined to the northern quarter, which is low, and where the drainage is less efficient and sanitary "arrangements generally less attended to than they are in other parts of the town." This statement of the case points directly to the remedy which is in the hands of the municipal authority, and which that authority should be called on directly to apply.

20. Dumraon town in Shahabad yielded a cholera death-rate of 8·18 per 1,000. It is stated to be "a fairly clean town," but we have long ago urged the little importance to be placed on mere surface cleanliness, because the filth which causes disease is not there, but in the compounds and houses with cesspits and wells dug close to others in the same foul ground.

21. Mozufferpore district had a cholera death-rate of 4·68 per 1,000, and 16 per cent. of the villages were attacked. Nothing is said about their sanitary condition, but two statements are made about the disease which may be quoted. The first is that "the people in this district are generally "fully aware of the dangers arising from visiting or in any way approaching cholera-infected "localities." This is as it should be, only every effort should be made by sanitary improvements to diminish the number of these cholera localities. Keeping out of them until they are improved or cholera ceases is the only measure of separation of the least use. But that the danger lies in the affected locality is shown anew by the other remark of the civil surgeon, who says:—"The people "from affected localities congregate in large numbers in and about the markets held weekly in the "district," and he records "that he has failed to connect the spread of the disease with the free "intercourse which takes place at these markets between the people from affected with those from "healthy villages." In these two statements are contained a whole history of cholera in its practical bearing on sanitary work and precautions.

22. The following facts about cholera in Durbhunga district are also of interest, because they include climatic conditions, epidemic movement, and the effect of local conditions. In 1881 the cholera death-rate was ·12 per 1,000, and 2 per cent. of the villages were attacked. In 1882 the death-rate mounted up to 4·14 per 1,000, and 29 per cent. of the villages were attacked. The maximum mortality took place in April, May, June, and July, chiefly in May and June. The months of June and July had abnormally deficient rainfall; the rains were re-established in August, and the deaths fell from 3,754 in June and 1,686 in July to 567 in August, and thence to 26 in December.

The civil surgeon thinks that the disease crossed the Ganges from North Bhagulpore. The magistrate refers its localization to "the filthy habits of the people and to the stagnant tanks, which form a network all over the district." These facts are in no sense contradictory, but, taken as a whole, they teach us that, while we can neither control or turn aside epidemic movement nor influence rainfall, we can deal with the localizing causes described by the magistrate.

23. Sarun district suffered severely from cholera, and "the presence of the disease," says the civil surgeon, "could not be traced to or explained by local insanitary conditions." Were this view

correct, Sarún would stand out in marked contrast to other Bengal districts. But the statement only shows defective inquiry or incorrect estimation of the facts. Such, besides, is not the view of the magistrate, "who informs us that the cause of excessive virulence of cholera in the subdivision in "which it raged cannot be said to have been *ascertained*, but it is the worst-drained tract in the "subdivision, and is, therefore, always more or less in an insanitary condition." This case appears to have been one of those in which cholera and bad sanitary condition prevailed over a certain area of country, and where, from some not very evident cause, it was more fatal in one portion of it. The reason assigned by the magistrate is probably the true one.

24. Cholera prevailed in Monghyr district of Bhagulpore division during every month of 1882 except December, and yielded a death-rate of 2·71 per 1,000. All the registration circles recorded cholera deaths, and these deaths, which numbered 5,351, took place in 681 villages out of 3,457 in the district. It is necessary to bear this history in mind to be able to estimate the value of the following importation case, of which, be it observed, no details or dates are *given*. "This year a man in his "way back from Deoghur died of the disease at Khyra, and immediately afterwards an epidemic "conflagration was set up in that village, spreading rapidly to the three northern thanas." Cases reported in this fashion require no comment. It might, apparently, be urged that the *man fell a* victim to the village cholera rather than the village to the man. In Jamalpore thana in *this district* the cholera death-rate attained no less than 19 per 1,000, showing high epidemic intensity.

Another importation case from a specified village is given for Bhagulpore district, but it was found on inquiry that there was no cholera to import.

25. There is an importation history, given more in detail, which requires special notice, in connexion with Caragola fair, towards the end of February, when the people began to disperse. As already stated, an "insignificant" outbreak took place at this fair, and it is on this occurrence that the history hangs. The precise dates of the fair, the numbers present, the sanitary measures adopted, and the number of cases, are not given. The only facts dwelt on are the fair and the dispersion of the people; all else is a matter of opinion. The site of Caragola fair is in Purneah district of Bhagulpore division, in which there were 8,777 deaths from cholera, and 23,919 cholera deaths in the division. The fair was held some time in February, but the alleged outbreak took place after the dispersion of the people at the end of the month. In Bhagulpore division there were 19 cholera deaths in January and 636 in February. Purneah district yielded 511 of these deaths in the same month. So that whatever influence the fair exercised, it could not be blamed for having caused the epidemic, which indeed covered nearly the whole of Bengal during these two months. In the course of the year every registration circle in Bhagulpore division returned cholera deaths, and 2,636 villages out of 22,658 were affected. Now, although the amount of cholera at this fair is styled by the Sanitary Commissioner as "insignificant," it is considered to have spread the disease to all the district by travellers from the fair. The statistics show conclusively that cholera prevailed at the time over the entire province within an area about 600 miles in length by about 400 in breadth, and along certain roads there were, as there always are, people travelling; and in the absence of any facts to show the relation of these people to cholera prevalence, we are expected to place the two events in the relation of effect to cause, or at all events to assume the arrival of people in this special case as the cause for the epidemic in Purneah and Bhagulpore, for it was an epidemic. There are three views given of the etiology by the civil surgeon:—

1st. That the disease was communicated by human agency from Caragola.

2nd. That its spread was attributable to contamination of the water-supply.

3rd. Amongst the predisposing causes of outbreak at the fair are enumerated "excessive overcrowding, want of suitable shelter, days and nights of fatigue, indiscriminate use of food, bad water, "atmospheric changes, and the like; and then the magistrate reports that only a few cases of cholera "actually occurred at the fair." If we knew how many people were at the fair, the number of cholera cases there, and the sanitary precautions actually adopted, we should be better able to form a judgment on this case; but, taking the facts as they stand, they appear to show that, at a time when a great epidemic was about to break out, and when it had already shown its presence all over the province, this fair was held, and the people dispersed at the time of the outburst, and were exposed to the usual influences of fatigue, crowding, &c., in villages where cholera already existed or was on the eve of appearing, and some of them suffered. This appears to have been the real history. There is no necessity to invoke "contagion" as a cause, for all the facts of the Bengal epidemic of 1882 render such support unnecessary, and it is quite certain that "contagion" can give no account of the year's cholera statistics.

Our view of the facts is that opinions resting on bases so slight should never appear in sanitary reports, but what ought to have appeared in full was a statement of the sanitary condition of affected groups of population, where the pilgrims lodged, for which we search in vain in the Purneah cholera report. But even the general statement of local causes elsewhere, so far as it goes, is very instructive, and points to the real remedies. For example, the sub-divisional officer of Godda, from his own personal observation, reports "that cholera was most fatal wherever the villages were filthy and "overcrowded, and where the water-supply is impure. Such was the case notably in Matin, Dureh, "Maheshpur, Belhudda, Bhaska, Lohondia, Bazaar, and Jaharkitta, in Barkope." It is obvious that if pilgrims from Caragola fair entered villages in this condition, and just at the time when a great epidemic was coming, they would almost certainly suffer, but if the contagion etiology be adopted, the fair would have to bear blame, and not the villages. Seeing that this group of villages was inspected, why should they not have been taken in hand at once and improved? This is the logical conclusion from the facts. Cholera was very fatal in Orissa division, and a similar account of the infected villages is given.

26. The year's epidemic condition of cholera extended from the land to the river population. European sailors had a death-rate of 14·69 per 1,000, and the native population yielded a rate of 4·52 per 1,000.

27. We have to thank the Sanitary Commissioner for his statement of the localizing causes of cholera during the great epidemic of 1882, which we have abstracted as briefly as possible on account of the importance of the facts to future sanitary work. Of course, it has been long known that the population lived under these unhealthy conditions, but in the year's epidemic history the relation of these conditions to epidemic prevalence has been clearly shown. Filth and foul domestic water everywhere invite the entrance of epidemic cholera when it is passing over a country, and it will continue to find a welcome until these conditions have been abolished. The cause and the remedy are both known, and it rests with the Government of Bengal and its officers to apply the remedy.

28. *Small-pox.*—While the mortality from cholera showed a large increase in 1882, it is satisfactory to find that the deaths from small-pox underwent a considerable diminution, as will be seen from the following death-rates for the last four years:—

Years.	Total Deaths from Small-pox.	Ratios per 1,000.
1879	22,843	·34
1880	22,953	·34
1881	24,371	·36
1882	13,651	·20

In 1882 the small-pox deaths divided between town and country circles were, for,—

Urban circles deaths	853
Ratio per 1,000	·34
Rural circles deaths	12,798
Ratio per 1,000	·20

The next abstract shows the monthly incidence of small-pox mortality in 1882:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	1,370	July	819
February	1,911	August	428
March	2,571	September	279
April	2,100	October	195
May	1,888	November	221
June	1,461	December	388

LIBRARY OF THE BOMBAY BRANCH OF THE ROYAL ASIATIC SOCIETY.

Small-pox was least fatal during the hot months of 1882. Deaths from this disease were returned from all the 45 registration districts, also from 365 out of 644 circles of registration, but out of 201,989 villages the deaths were returned from 5,801. The epidemic covered the whole country in low intensity, and the deaths were confined to little more than 2·8 per cent. of the population groups. The mortality was nowhere very high, but it was greatest in Chittagong and Orissa divisions.

29. The following abstract shows the year's vaccination work:—

	Total Number of Vaccinations.
Calcutta	11,373
Metropolitan circles	344,178
Suburbs of Calcutta	15,152
Vaccination circles	831,618
Municipalities and dispensaries	59,104
Total	1,261,425
This total includes,—	
Primary operations	1,247,277
Secondary "	14,148
Total	1,261,425

Of the total vaccinations of the year there were successful,—

Primary operations, 1,223,561 = 98·69 per cent.
Secondary " 5,497 = 45·12 "

The ratio of primary successful vaccinations was nearly the same in the preceding year, viz., 98·89 per 1,000.

The next abstract shows the ages of vaccinated subjects, together with the ratios at each age to the total successful vaccinations :—

	Successful Vaccinations.		
	Under one Year.	One Year and under Six.	Above Six Years.
Total number vaccinated - - -	158,979	823,129	241,453
Percentages of total - - -	12·81	66·38	19·45

By assuming a birth-rate of 30 per 1,000 of the population, the Sanitary Commissioner calculates the births at 1,299,183, and by comparing this number with the ages of vaccination, it will be seen that much extension of the work is necessary before the ground is covered. Nevertheless, the year's experience shows that life has been saved, as the following facts appear to prove :—

State of Vaccination.	Small-pox Deaths per 1,000.
Thoroughly protected areas - - -	0·02
Fairly well ditto - - -	0·09
Very partially and unprotected ditto - - -	0·26

The next abstract gives the results of a certain number of examined cases to show the efficiency of different protecting agencies as contrasted with non-protection :

Subjects of Attacks and of Deaths.	Attacks of Small-pox.	Deaths from Small-pox.
Vaccinated - - - -	494	57
Inoculated - - - - -	158	86
Previous small-pox - - -	29	5
Unprotected - - - - -	2,120	382
Total - - -	2,801	530

These numbers refer of course to a given group of small-pox cases, but they are interesting and instructive. Of the total attacked the *vaccinated* yielded 17·63 per cent., the *inoculated* 5·64 per cent., and the *unprotected* 75·68 per cent. In the same way 11·53 per cent. of the deaths were yielded by the *vaccinated*, 54·43 by the *inoculated*, and 18·01 by the *unprotected*. It is impossible not to conclude, in this case at least, that inoculation was the means of augmenting small-pox mortality.

30. The staff engaged in vaccination was as follows :—

Rank.	Government Agency.	Licensed Agency.
Superintendents - - -	7	3
Deputy Superintendents - -	5	8
Superintending Vaccinators -	35	64
Vaccinators - - - -	339	825

The total inspecting staff amounted to 122, and the vaccinators numbered 1,164. During the year there were visited by the inspecting staff 27,274 villages. The total outlay for both agencies was 12,408*l.*, and the average cost for each successful case was 1 anna 7¼ pies, but the Government agency expended 3 annas 3¾ pies per successful case, against 10½ pies spent by licensed agency.

These data will give a sufficient idea of the vaccination work of the year. But most of the Report does not require remark, because of its strictly departmental character.

31. *Fevers.*—The section of the Sanitary Commissioner's Report which deals with the fever history of 1882 is one of the most important parts of the year's work, for it really includes as an appendix the report of a Special Committee appointed to inquire into the relation of fever in Nuddea in 1880 and 1881, to certain public works, railroads, roads, embankments, to the execution of which the high fever death-rates had been in part attributed. The fever section itself contains the statistics, together with local notes on fever causes, prepared by the civil surgeons, and the special report, prepared under the presidency of Dr. Lidderdale, contains many facts which, although not new, are nevertheless so analysed as to enable a more accurate idea of these local fever causes to be formed which have helped in times past to decimate the people by outbursts of epidemic diseases.

32. We shall begin our remarks on this section by introducing the following statistical statement of fever deaths in Bengal for the last 12 years:

Years.	Fever Deaths.	Ratio per 1,000.
1871	169,505	2·56
1872	237,868	3·59
1873	303,645	4·59
1874	328,721	4·97
1875	368,087	5·56
1876	561,537	8·49
1877	711,036	10·75
1878	742,887	11·23
1879	622,260	9·41
1880	689,605	10·43
1881	940,911	14·23
1882	929,943	14·06

If the registration of fever deaths had been reliable for these 12 years this table would have furnished matter of alarm. But we may take for granted from the figures that the five earlier years only show that during that period at least the registration was defective. In subsequent years the registration has been improving, but since the scarcity years 1877–78, and their high fever death-rates, fever has either been increasing in Bengal or we are coming closer year by year to the real death-rate. This latter seems the more likely assumption, because in none of the years has the fever death-rate arrived at ascertained rates within certain known limits where the real facts admitted of being arrived at. Another cause of uncertainty is one we have often alluded to, namely, errors in diagnosis. In the present Report, as we shall see, fever deaths are sometimes attributed to ascertained fevers of malarial type, in another fever locality the fever deaths are attributed to supervening pneumonia, and in other localities to the usual complications such as spleen disease, diarrhœa, dysentery, and the like. All, however, are included in the present returns under the fever heading. There is no way out of these difficulties at present, but so far as relates to sanitary work, they are not likely to throw any impediments in the way of it.

33. The next abstract gives the monthly prevalence of fever in Bengal for 1882, and for the preceding five years, together with the monthly rainfall for 1882:—

Months.	Fever Deaths in 1882.	Rainfall in 1882.	Average Fever Death, 1877 to 1881.
January	87,810	·09	63,815
February	67,010	·78	50,849
March	71,519	·59	52,902
April	67,868	1·07	55,692
May	67,517	5·13	50,791
June	60,840	9·61	46,504
July	67,390	10·65	48,466
August	69,935	12·50	55,883
September	74,427	9·23	59,054
October	86,847	6·81	72,041
November	101,207	1·16	91,396
December	108,073	·04	93,943

If we assume the monthly rainfall in this abstract as approximately expressing the monthly ratios of rain over the province, we necessarily arrive at the conclusion that increasing and cumulative rainfall increases fever mortality, that the increase proceeds after rain has diminished, that lowering and variable temperature causes increase of mortality in November and December, which increase passes on to the following year, and then declines until the next rainy season comes round, when the same course is resumed. We shall presently see that there are other fever causes, besides periodical rain (which we cannot control), that are in operation to increase the season death-rates, and which are to a great extent under our control if we choose to exercise it. Rainfall is hence an index or test of local sanitary condition, rather than a direct disease cause.

34. In 1882 fever was universally prevalent in the province, as is shown by the fact that all the 644 registration circles returned fever deaths. Of 201,989 villages, fever deaths were returned from 134,812. The average fever death-rate from town districts was 15·72 per 1,000, for country districts 14·00 per 1,000, and for the entire province, 14·06 per 1,000, against a previous five years' fever rate of 11·21 per 1,000. The difference between the two rates, 2·85 per 1,000, shows the epidemic increase during 1882.

The fever rates varied considerably in different districts. The lowest of the year was in Darjiling. This was 4·58 per 1,000. In several districts the rate was under 10 per 1,000. The highest rate was in Nuddea, where the special inquiry already referred to was carried out. It was 30·18 per 1,000, against a previous five years' average of 21·96 per 1,000. In a number of towns the fever-rate was under 10 per 1,000. The highest town rate of the year was 37·21 per 1,000 at Bishenpore, in Bankura district.

35. We shall next give some account of the local causes of these fevers in the districts, abstracted by the Sanitary Commissioner from the Civil Surgeon's reports.

The first is an observation made by the Sanitary Commissioner himself,—that native workpeople who used for drinking, water which had passed the condensers of steam engines at the factories where they were employed, "enjoyed better health and greater freedom from attacks of epidemics or malarious diseases than the neighbouring population." There can be no difficulty in pursuing this inquiry, as all the materials for it are on the spot. If the results were confirmed, they would afford a new illustration of the utility of boiling impure water before drinking it, and this on a large scale. There is no practical objection against accepting the results, because the chemist has discovered organic matter in the boiled water. It is not the amount of such matter, as it exists in soup, for example, which is injurious. The danger lies in the fact of putrescence, and this is arrested for the time by boiling. But if the experiment were perfectly successful, it could never justify the proposal in the Report to substitute it for the introduction of wholesome water to every town and village in the Presidency.

36. On the subject of local causes we find the usual intermingling of important facts with quite useless theoretic matter. In sanitary work we can only spend money on observed facts, and these which are given are sufficient to justify outlay both of money and effort. Take, for example, the case of Burdwan, which has suffered for years from fever. In this district 89 per cent. of the villages yielded fever deaths in 1882. The magistrate states that "village sanitation is still in a very back-"ward state; although the interior of the dwelling-houses in the mofussil are tolerably clean, the "surroundings thereof are in a most filthy state; cesspools, tanks overgrown with weeds and noxious "vegetation, and ashpits in which the sweepings of the cow-houses and decomposed vegetable matter "are thrown, abound in almost all rural villages. Persuasion and advice have failed to secure im-"provement. It is very difficult to induce the people to attend to the sanitation of their own villages, "and the zemindars, except in one or two instances, have done very little to improve the sanitary "condition of their tenantry." The only remark called for by this statement is, that the case as described is precisely one of those in which the authority of Government should be called in to grant competent powers for dealing with villages and zemindars, and to see thereafter that the work is effectually and continuously carried out. What defence is possible in face of the fact that the registering circles had 2, 3, and 4 per cent. fever death-rates—one of them, indeed, 43·75 per 1,000—and of this other fact, that since the previous census, Burdwan district had lost 92,027 of its population?

37. The villages in Bankura district appear to be even in a more unfortunate position. In one thana the fever death-rate was 46·00 per 1,000, and 48 per cent. of the district villages suffered. "In the town of Kotulpore the disease assumed a virulent type from the beginning of July. This "town was in a filthy condition, containing many stagnant pools, refuse and cow-dung pits, and "loathsome ditches, while the banks of tanks were freely used for the purposes of nature. . . . "People of all ages and conditions suffered from fever, and in many villages the entire population "was prostrated. . . . Water for drinking and culinary purposes obtained from tanks which "have not been cleaned for years, polluted by all sorts of filth, their banks defiled by the village "people, whose excreta are left to be eaten away by pigs or dogs, or to drain away into the tanks. "Heaps of refuse and decaying vegetable matter deposited on the slopes of these tanks."

38. In some of the circles in Birbhum the death-rates from fever were as high as 3 per cent., and in one thana the rate was 87·64 per 1,000. In this case declining health, consequent on previous fever attacks, was observed, and that relapses, added to "the cachectic condition and low state of health of the people, induced by previous repeated attacks, caused the mortality to be heavy."

39. In Midnapore district "the local insanitary conditions, canal irrigation, and the filthy habits "of the people continued to be the same as usual, and no general or local sanitary measures were "effected which could have had the slightest effect on the general health. . . . The constitutions "of the people living within the epidemic area of Midnapore have become impressed by malarial "influence; cachexia, anæmia, and enlargement of the spleen, has become extremely common."

40. Fever in Serampore district is attributed to obstructed drainage, want of drainage, and impure drinking water.

41. With reference to the fever in Howrah district, the magistrate makes the following remarks:—"The large swamps, only a few miles from the town, are well known, and until they are drained "it is not likely that the health of the district will materially improve. . . . I do not know why "there is so much delay in proceeding with the work, which is of the first importance. The villages "are exactly as they were, and will remain so until the people get more educated, or the authorities "have greater legal powers." If additional legal powers are required, why should they not be given?

42. *Fever in Nuddea.*—Referring to fever in 1882, the Sanitary Commissioner makes the following remark on its prevalence in Nuddea:—"For the third year fever has prevailed pre-eminently and "and with most marked fatality in this district. The extent of the suffering may be gathered from "the following figures:—88 per cent. of the villages, against 90 per cent. in the preceding year, "suffered from the disease; 60,912 persons, or at the rate of 30·18 per 1,000, against 36·27 per "1,000, perished." In some of the thanas the fever mortality reached 4½ and 5½ per cent. of the population. The civil surgeon, in describing this fever, says that "it was mostly of an intermittent "nature, frequently degenerating into remittent. Some of those affected died of the first attack

" from intensity of the poison, while in those with whom it took a more chronic form, enlarged " spleen, jaundice, occasionally enlarged liver, dropsy, and general anæmia, concluded the fatal course " of the disease." In this district we are also told that "no zemindars have rendered any assistance worthy of notice in improving the health of the people."

43. Fever in Nuddea has been attributed partly to interruption of the natural drainages of the country by embankments, roads, railroads, &c., and the Government of Bengal appointed a committee, already referred to, with the view of arriving at the facts. Their report is appended to the present Sanitary Report for 1882, and we shall include its information in the remarks which follow. The southern boundary of Nuddea is about 25 miles north of Calcutta, and the district is traversed by rivers and watercourses. Its area is 3,404 square miles, and its population in 1881, including that of the towns, was returned at 2,017,847, or in the ratio of 592·79 per square mile. Its registered death-rate in 1882 was 39·37 per 1,000, and the preceding five years' average death-rate was 27·13 per 1,000. The death-rate from fever amounted to 30·51 per 1,000 for the country circles, while the five towns returned fever death-rates between 12·14 and 31·66 per 1,000. The five years' average fever-rate for the district was 21·96 per 1,000. This is a high average death-rate from malarial fevers and their complications, and it is subject to considerable augmentation in certain years. The object of the special inquiry was to ascertain the causes of these fever losses and to point out remedies, and a sum of 5,000*l.* was placed at the disposal of the committee to meet urgent cases. The whole country was traversed, and 400 villages were visited by the committee, together with the roads, embankments, &c., which had been partly blamed for the fever. But the very first paragraph of the report shows the existence of topographical causes of another kind of the utmost importance to the public health. This paragraph is as follows:—"(*a.*) The district of Nuddea is a vast alluvial plain intersected by " six large rivers, numerous smaller channels, and by a labyrinth-like network of forsaken river-beds " and old rivers in every stage of decay and effacement. It is dotted with lagoons and marshes, and " studded with numerous towns and villages, which are frequently hidden in clumps of bamboos and " clusters of trees. The lands are closely cultivated. As in all deltoid formations, the fall of the " country is away from the rivers, but the regularity of the slope is broken up by the tangle of rivers " and river beds which cross and recross one another, and obstruct the natural lines of surface " drainage." This description applies to a fever country, rendered so by its natural features, and it is obvious at a glance that it would be practically impossible to change its topography, depending as this does to a large extent on changes in the great rivers continually going on. The real question therefore is to determine whether there are any removable causes over and above those due to the natural topography, which could be so dealt with as to lessen the liability of the people to fevers. And first, as regards artificial obstructions to surface drainage, the committee point out that one entire section of country "which has been visited by the fever epidemic with special severity is absolutely free from artificial obstruction as far as we could ascertain."

In this section therefore there is no evidence of this cause having been added to those already existing. In the case of Eastern Bengal Railway the drainage obstruction was due not to want of water-way, which had been found sufficient previously, but to the bursting of a river embankment and overflow of the country, breaching the railway in several places. Additional water-way has since been provided.

In another section, where the fever mortality was not high, a khal had been closed by the State railway, "regarding which loud complaints were made to us, and apparently with reason." This is an instance of merely local obstructions, of which a number are given in the report, and their bearing on the public health fully discussed. They are mainly due to absence of sufficient water-way under lines of road or railway, and admit of easy remedy. No doubt defects of this class might affect injuriously the sanitary condition of a district, but the committee point out that their effect would be strictly local, while the Nuddea fever covers the whole area of the country in an epidemic form. They might aggravate the disease in specific instances, but could not originate a fever epidemic.

Their opinion may be quoted as follows:—"The general result of our own investigations shows " that there is very little obstruction to local drainage caused by the roads and railways in the district " of Nuddea, and that such obstructions as do exist are not of serious importance, except on the rare " occurrence of unusually severe floods. Further, we have found that on most roads where drainage " was obstructed in times past, bridges and culverts have been gradually provided, or breaches have " been made to allow the floods to pass, whilst roads recently made have generally adequate " water-way."

We have already alluded to the local topography of Nuddea, but to complete the history it should be stated that the topography is by no means a fixed quantity in the sanitary problem. The features of the country are, on the contrary, liable to change by the river forces, whose natural action is to raise the surface level of the country until this work is done, and the river has to find a course elsewhere, while the old bed is silted up and may become a disease cause. These changes are taking place all over the Ganges delta, and "the delta in Nuddea and Western Jessore has been " raised and practically completed, and by the gradual deposition of silt the line of drainage, which " was formerly from north-west to south-east, is now from north-west to south. In other words, the " work that had to be performed by the Bhyrub, the Cobaduck, the Nobagunga, and the Mysore-" Chitra has been completed and the rivers have died. In their place, the little Elankhali Khal has " opened out into the great Madhumati, and the Gorai has enlarged; the formative energy has been " carried at one bound from the west of the Jessore district to the east of it." In dealing with great nature forces such as these, mistakes have at times been made, and we are glad to see that the committee "consider professional advice necessary in most cases of construction and renewal of river embankments." This advice is equally necessary when opening up old river courses, and in

providing for the drainage of areas over which public works have to be carried, in order to obtain the largest amount of benefit with the least risk.

We have already shown the relation of rainfall to fever mortality for the whole of Bengal, and we shall here give the data for Nuddea district, where they are of special importance in connexion with the topography. The monthly death-rates from cholera in Nuddea are also added, to show how different is the influence of the amount of rain on the fatality of the two epidemics.

NUDDEA, 1882.

Months.	Deaths from cholera.	Deaths from Fever.	Rainfall.
			Inches.
January	710	8,629	·09
February	851	4,911	·48
March	2,257	4,822	·59

August	33	3,236	12·50
September	45	4,298	9·22
October	272	6,280	6·81
November	1,072	8,455	1·16
December	1,420	8,060	·04

Topographically, as we have said, Nuddea is essentially a fever country, and if there were no other fever causes than those connected with its drainage peculiarities, the problem which it presents would be almost insoluble; but it is an axiom in dealing with such cases everywhere that the natural defects of locality can be, to a very considerable extent, counterbalanced by adopting precautions in house-construction, local drainage, water-supply, cleanliness, food, air, clothing, all of which are necessary for improving the health and increasing the resisting power of the inhabitants against general insanitary topographical conditions such as those discussed in this Nuddea report.

Let us see then what information the Report gives us on this part of the question; and first, as regards water-supply, the committee make the following statements:—"The water-supply of Nuddea is of the worst possibly quality;" with exceptions stated, "there is no good water in the district. . . . The tanks are generally small, more or less silted up, and often choked with weeds." As a rule, "in and near villages their banks are broken, and they in consequence receive surface "drainage, while houses are in many places built near the edge of the water, into which they directly "drain. The water is thick and foul, greenish and brownish in colour, and contaminated with "animal and vegetable *débris*, sometimes also full of animal life, and completely covered with floating "vegetation. . . . . The old class of men who used to dig tanks, sometimes for the benefit of "the public, sometimes for the good of their own souls, are gone. They have been succeeded by a "generation who lack their faith. . . . . The consequence is that most of the old tanks are in "ruins and overgrown with noxious vegetation, and the number of new tanks is very small." This state of the tanks has been partly caused by the erection of embankments to prevent floods, which otherwise would have swept over the country and replenished them. The same tanks are also used for bathing, washing clothes, and other domestic purposes, and half-burnt bodies of the dead are thrown into water sources.

In many places the water is rendered unfit for use by the erection of weirs across the flow. Local water-supplies in villages appear to be unfit for use. Such water is never drunk if any other can be obtained. "The people dislike it very much, saying that it disagrees with them, and has an un-"pleasant taste. Considering that the wells are sunk in the foul soil of the village, sometimes within "a few feet of graves, it is not wonderful that the water should be bad. There is a cesspool, and in "some larger places a well privy, often in the immediate vicinity, from which percolation must take "place directly into the well."

The following remarks are made on the villages:—"Besides the deficiency and impurity of the "drinking water, we found still prevalent in the villages themselves every insanitary defect that "former observers had noted, defects that are more or less common throughout Bengal. The bad "condition of the land on which villages are built is brought about by the mode of construction of "houses and the habits of the people. In a country with a heavy annual rainfall, and subject to "inundation, the houses must be well raised. Earth is used for this purpose, and a homestead or "'bhita' thrown up, and on the top of this a house is built with a plinth of mud. This necessitates "the digging of an adjacent hole, often very deep, and always undrained. One homestead having "been formed in the manner above given, another and another is added without arrangement of any "kind, generally crowded together, until the whole village is honeycombed with such holes. These "receive every sort of household refuse, and nearly all the year round contain water of the foulest "description." In these hovels the poor people prefer sleeping on the floor, because from want of sufficient clothing, they find it warmer to do so than to sleep on raised beds.

Next, as regards conservancy. "Well or surface privies are erected in many a homestead without "a thought or a care as to how they are ever to be cleaned, while, from want of latrines or particular "localities set apart for the deposit of household or other filth and refuse, the roads and open "grounds, especially the edges of tanks, are fouled with the grosser forms of pollution. In the

" village of Alikdeah, near Chooadanga, we found it almost impossible to get down to the water in " one of the tanks, its banks both outside and inside were so covered with filth, yet the water of this " tank was being drunk. The mortality in this village was enormous. . . . Cattle dung is, as " a rule, never removed outside the village." It is thrown on to the roads, and left to rot and waste, while " there is a consensus of opinion among Europeans and natives that, except in the lower lands " used for the rice crop (amun dhan), reaped in the cold weather, there is a distinct decrease in the " fertility of the soil of Nuddea. Yet tons of the finest manure in the shape of cowdung are " available in every village, but this supply, which, if utilized by the cultivators, would restore " the fertility of their lands, is not only wasted, but is allowed to degenerate into a positive " sanitary evil." Again, "In the villages of Nuddea human beings and animals live in the " closest proximity, and overcrowding at nights is general in the huts, which, moreover, are un- " ventilated."

(*i.*) *Clothing.*—"The people seem as a rule to be badly supplied with clothing."

(*k.*) *Diet.*—"The diet of the lower classes is of inferior quality. Rice, with a small supply of poor " watery vegetable or dhall, and a little salt, is their daily fare."

(*l.*) To complete this most sorrowful picture, it remains to be said that out of 1,923,682 people inhabiting these Nuddea villages (in 1881), there died in 1882 no fewer than 10,936 from cholera, and 58,694 from fevers, affording a death-rate from these two diseases of 36·02 per 1,000.

(*m.*) We believe that a careful consideration of these facts can lead to but one conclusion in regard to these Nudden fevers, and this is, that, whatever may be the influence of local topography or climate on the public health, and whatever may have been the effect of those local drainage obstructions described in the Report, neither of these supposed disease causes would account for the facts, and, if this be true as regards Nuddea, there is every reason to believe that it holds equally true as regards the whole cholera and fever endemic area of Lower Bengal. There is no reason to doubt that malaria enters into the chain of causes, but the results are due to malaria and filth. Malaria is no doubt a general predisposing cause all over the Ganges delta, but it is a perfectly fair question to ask, would malaria produce these results, or anything like them, if the subjects of fever and cholera, the inhabitants of these villages, were endowed with sufficient stamina to resist malaria? Of course, the question implies its own answer.

(*n.*) But this inquiry is of importance in another direction altogether, because it raises the whole sanitary question in regard to the *modus operandi* of conditions under which the people within Dr. Bryden's endemic area live. It is impossible in the present inquiry to separate between malarial fevers and cholera as regards their causes. Statistical facts and local observations, such as are contained in the Nuddea report, prevent us from making any separation between the causes of these two endemic diseases."

The local facts all go to prove that the mass of the population live amidst surroundings by which their resisting power is impaired or destroyed, and of this malaria is the touchstone. Why a certain part of the people in 1882 should have died of the disease called "cholera," and why five times and upwards of this number should have died of "fever," while all were existing under precisely the same conditions, is a question we have no means of answering, unless we assume a close relation between the diseases.

(*o.*) Fortunately, for practical purposes it is not necessary to solve the difficulty, for it is certain from the facts that the same sanitary procedure is required to diminish the liability of the people to cholera which is required to diminish their liability to fever.

In the present state of the population it would, of course, be impossible to execute drainage works of such magnitude as would be required to remove the local causes of malaria in the Ganges delta. Wherever similar works have been carried out, they have been the result of long years of continuous and skilful labour. In the present case the committee recommend for Nuddea what appears to be the only feasible course, namely, to provide a remedy for observed local drainage defects. They give a list of defects of this kind in waterways, culverts, bridges, and the like, that came under their own immediate observation; but there can be little doubt that similar deficiencies in local drainage outlets exist more or less over all the low lands of the delta. The results of the Nuddea inquiry appear to show that providing for and keeping open of local drainages requires to be set on foot under professional advice, and to be subject from time to time to professional inspection. It need scarcely be said that all future railways, roads, &c., should be provided with sufficient water-way to prevent water-logging.

(*p.*) But if all improvements of this class were completed, the main fever and cholera causes would be left as they are. They have been fully described by the committee, and we concur entirely in their view that "all of them are within the immediate power of the people themselves to remove. . . . " . . . Under the guidance of Mr. Taylor," they say, "and his subordinates, a few villages have " tried to improve their condition by clearing jungle, forming burial grounds outside the villages, " raising subscriptions for the improvement of roads and drains, and in other ways; but very much " remains to be done," and they advise that "more power must be given to district committees, such " as is contemplated in the Bengal Government's letter, No. 9,212, dated 8th April 1882." And they conclude with the following hope, in which we most sincerely join, by saying, "We, however, feel " that it is sufficient for us to call attention to these sanitary defects, and to leave it to the experi- " ence of the magistrates and committees to frame such bylaws concerning them as may meet the " peculiarities of their respective charges."

So far as the facts in this special Report enable us to judge, the same remedies would be applicable to all fever localities in the delta, and the case is now in the hands of the executive authorities, who will henceforth be morally responsible for the health of the vast population over which they rule.

44. The amount of information about fever causes in the Nuddea Report renders it unnecessary for us to discuss at length the fever history of other districts, and we shall only notice such points as appear to throw light on the subject generally.

In Jessore, it is stated, that "no assistance has been rendered by zemindars and others by under-"taking sanitary works for the benefit of the people. And, moreover, that the fever in the district "was attributable to the obstruction of the natural drainage of the country for the purpose of growing "paddy."

45. The following hopeful fact is stated about the town of Rungpore: "The drainage operations "carried out in the marshes around the town of Rungpore have been of the greatest benefit. They "have removed to a considerable extent the hitherto extremely water-logged condition of the soil. "The scheme was commenced in 1877, and year by year, as the work progressed, a marked improve-"ment revealed itself in the health of the town."

In 1878 the death-rate of Rungpore was 34·22 per 1,000, and in 1882 it was 23·64 per 1,000. Its fever death-rate, 18·39 per 1,000, was still high.

46. But on the other hand, many villages and tracts (in Pubna district) are relapsing into complete jungle, owing to the locality becoming unhealthy.

47. At Darjiling there are imported fever causes of the following kind. Good houses are built with bad sanitary arrangements, and disease results. One case is given in which puerperal fever resulted from the state of the drains. Inspection of works is needed at all sanitaria in India for the prevention of disease causes of a totally different kind than those which afflict the native population.

48. In certain parts of Dacca fevers are increasing, on account of silting up of water-courses, consequent on changes in the direction of rivers and underlying clay subsoils.

49. "The town of Rajmehal is said to be a regular hotbed of fever, with its notoriously crowded "houses, stagnant tanks and pools of water, rank jungle, accumulations of filth and rubbish, well "privies, cesspits, &c." There is besides a large swamp in its vicinity.

50. These facts, taken from the reports, appear to give a sufficient account of the general fever causes in Lower Bengal and the nature of the required remedies. As already stated, the whole question must now be considered as having passed over from the sanitary inquirer to the executive authority. Again and again there is complaint that the zemindars will give no help to the people to help themselves; and so the evil will not only continue, but go on increasing year after year, unless the strong hand of the Government interferes to put an end to it.

In comparison with the losses from epidemics the losses from other death causes are of less importance, and are mainly due to the same sanitary defects. We shall, therefore, merely give the year's statistics under the usual headings.

51. *Bowel Complaints.*—Under this head were registered 61,362 deaths in 1882, of which 9,700 were returned from the urban, and 51,662 from the rural circles. The total death-rate was ·92 per 1,000. The monthly incidence of these diseases was as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January - -	5,217	July - -	5,727
February - -	4,286	August - -	5,985
March - -	4,675	September - -	5,125
April - -	4,452	October - -	5,021
May - -	6,042	November - -	5,230
June - -	4,860	December - -	5,637

These monthly numbers bear no marks of any relation subsisting between bowel-complaint mortality and climatic causes.

The deaths were returned from 23,670 villages out of 201,989 in the province, and from 623 registration circles out of 644.

52. *Injuries* gave rise to the following deaths in 1882:—

Suicides	Males - - - -	944
	Females - - - -	1,470
Wounds - - - - -		1,229
Accidents - - - - -		8,558
Snake-bite and wild beasts - - -		9,410
		21,611

It is worthy of remark that deaths from wild animals formed 43·54 per cent. of the total deaths from injury.

Under the head "All other Diseases" were classified 140,732 deaths, or 2·12 per 1,000 of the population.

53. *Port of Calcutta.*—Before concluding this account of the disease history of Bengal and its relation to local causes, we shall introduce a brief notice of diseases prevalent in the port of Calcutta.

The port population of the year is not distinctly stated. There appears, however, to have been a considerable increase in the number of European seamen, "for augmentation of marine trade brought 1,792 mariners to Calcutta in 1882 against 1,350 in 1881."

Among European sailors there were 41 deaths from cholera, stated to amount to 14·69 per 1,000, against 11·83 per 1,000 in 1881. In 18 of the attacks "it was known that drunkenness and exposure to rain and cold preceded the attack."

Fever cases and deaths among European sailors are stated as follows for 1882:—

Fevers.	Cases.	Deaths.	Deaths per 1,000.
Malarious fever - -	251	5	1·79
Simple fever - -	186	—	—
Enteric fever - -	8	6	2·14

There were among the same class 143 cases and 2 deaths from diarrhœa, and 146 cases and 8 deaths from dysentery. The death ratio for the former disease was ·71, and for the latter 2·86 per 1,000.

Among the native floating population there were 115 deaths from cholera, or 4·52 per 1,000; besides 26 deaths, or 1·02 per 1,000 from malarial fevers. The epidemic death-rates on the river were all higher in 1882, keeping pace in this particular with the greater severity of epidemic disease on shore.

54. *Sanitary works (Civil).*—Under this head are given returns of expenditure from 184 municipalities and unions in Bengal. The total amount available in 1882, including the past year's balances, was 310,673*l.*, of which 36·75 per cent., or in round numbers 100,000*l.*, was spent on sanitary works, against 23·93 per cent. in 1881. The increased sanitary expenditure in 1882 is in great part due to the removal of police charges from the municipalities, a step which enabled them to pay more attention to practical sanitary work.

The expenditure arranged under the usual heads stood as follows:—

Nature of Expenditure.	Per-centage of Total Income.	
	1882.	1881.
Conservancy and latrines - - - -	8·4	6·1
Ditto establishment - - - -	10·1	10·4
Drainage - - - - -	4·4	2·1
Water-supply - - - -	1·0	·95
Disposal of dead - - - -	·22	·19
Markets and slaughter-houses - - -	·45	·22
Vaccination - - - - -	·38	·33
Treatment of sick - - - -	4·0	2·5
Other sanitary works - - - -	1·8	1·1
Roads - - - - -	18·14	16·2

Considering the large population over which these charges are spread, the amounts are very small. The one satisfactory point shown by the table is that the expenditure on public health measures has been augmented. But except, perhaps, in some of the unions, the vastly superior village population is unrepresented in this abstract.

Appended to the Report is a list of places where sanitary works under the preceding heads have been begun or finished during the year. In many places public latrines and conservancy plant have been provided, and the practice of collecting and trenching sewage is being extended. Under this head it may be stated that Rungpore municipality has established a vegetable garden on a trenching ground, where English vegetables are grown and "freely sold to the public." This is an important work, and might be extended all over Bengal, and thus, while public health might be protected from an abominable nuisance, great additions might be made of the public supply of important articles of diet.

The following improvements have been carried out in five important bustees in the suburbs of Calcutta. These bustees "were reclaimed at a cost of Rs. 13,001. The improvements consisted in "the ground being levelled, broad roads constructed, good tanks provided, drainage improved, houses "removed and rebuilt in systematic order, arrangement made for the construction of future buildings "in regular lines only." Similar improvements are being carried out in Howrah, and a new station (Khoolna) was being properly laid out. This work is very important, for it is not only a beginning of a reform which must in time be extended, more or less, all over India, but it shows that the thing can be done. We are glad to see that several of the more prominent unhealthy local causes referred to in preceding paragraphs as connected with the epidemic history of 1882 were being dealt with by the

municipal authorities, and also that, notwithstanding the general complaints made of the inattention of zemindars to the interests of the people, there have been a number of cases where, together with local proprietors, they have executed real improvements.

Under the head of *Drainage* it is stated that "the great drainage scheme in the Lalbagh municipality in the Murshidabad district was almost completed at the close of the year," at an outlay of 3,291*l.*

In a considerable number of localities drainage works of greater or less extent were in progress, and "a good deal had been done" for Nuddea. In this fever-stricken district drainage improvements were in progress. One of these would, it was expected, improve the sanitary condition of a tract of country 20 miles long and a mile wide. Drainage surveys were in progress in several localities.

Water-supply.—Burdwan water-supply scheme had been undertaken. The Howrah scheme was under consideration, and also that for extending the Calcutta supply to the suburbs. In Pubna town a simple but important innovation in water distribution was introduced by the magistrate, who appears to have paid the cost. The neighbouring river was bunded, and a pump and iron cistern supplied, to "the great convenience of the people."

In Dushumga town 232 small tanks and 145 pools, &c., were cleared out, at the cost of their owners.

The "first sod" on the site of the new waterworks for Bhagulpore was cut by His Honour the Lieutenant-Governor in November 1881.

A long list is given of localities in which the water-supply was being improved by the excavation and cleaning out of tanks and wells, so that this most necessary work was making progress. But all of it taken together is a very small item in the general needs of the people.

55. Among the sanitary proceedings of the year was the extension of sanitary clauses of a number of Bengal Acts to municipalities and other authorities, to enable them to deal more effectually with local disease causes. One of the latest of these Acts (11, B. C., 1882) has an important bearing on the Nuddea case, and others like it. It confers power "for the better construction, maintenance, "and management of embankments and watercourses, the maintenance, alteration, or removal, &c., "of embankments, railroads, &c., which interfere with drainage, or of watercourses, sluices, &c., "which affect public health, and for preventing the construction of dams or other obstructions for "diverting or opposing the current of a river or watercourse whereon there are embankments."

If these powers are applied under proper engineering advice, they will enable a great disease cause in Lower Bengal to be removed. Another important Act relates to the better regulation of coolie traffic to labour districts, as regards medical examination, diet, clothing, comfort during transport (which should include efficient and wholesome shelter at night), regulation of labour, &c.

There is also an important Act (V., I.C., of 1883), bearing directly on the question of substituting sanitary measures on board ship in lieu of quarantine. It grants very extensive powers of inquiry, and will do much good in tending to keep crews and vessels healthy.

A Bill for extending local self-government in Bengal, with the special object of enlisting the services of natives in improving the sanitary state of the people, was under consideration.

We are glad to see that, in consequence of a recommendation made in a previous year's Memorandum, the floating population have been placed under inspection, for the discovery and treatment of diseases among them.

56. In compliance with Government orders, a set of rules has been issued for the guidance of vaccination officers, which include inspection and report on the "sanitary condition of villages, and "sources of insalubrity affecting the health of their inhabitants, prevalence of disease in epidemic "and other forms, topography, population, dwellings, roads and streets, water-supply, conservancy, "disposal of the dead, food, general health, steps taken to explain existing sanitary defects to the "people, and to induce them to abandon habits which tend to produce unhealthiness amongst "them." In the course of the year 1,292 villages were inspected and reported on. The number was very small when compared with the total of 201,989 villages in the province.

The defects found by inspecting officers were the following:—"Badly-constructed and ill-arranged "dwellings huddled together, no regard to space proportioned to the number of inmates or to the "free admission of light and air; narrow and ill-constructed roads, with still narrower and more "tortuous lanes and bye-lanes, unprovided with side drains, and useless as arteries for the circu-"lation of air: entire or almost entire absence of conservancy arrangements of any sort; defæcation "and micturition performed in any convenient place, human and animal excreta, together with all "kinds of domestic refuse, piled up and accumulating near houses; water drawn from any and every "source, regardless of pollution, and used for drinking and cooking purposes; banks of tanks, "rivers, and streams used by preference for all the purposes of nature; the water defiled by bathing, "washing of utensils or of vestments fouled with the excreta of the sick, the exudations of loathsome "skin diseases or the discharges of menstrual women; drainage either completely absent or else "defective and obstructed, or, if good, intercepted by bunds or other more noxious impediments; "excavations, dug indiscriminately in all kinds of situations, and allowed to become the receptacles "for every description of filth, or the basins of stagnant pools, &c." After alluding to the difficulty of making the people comprehend the importance of these conditions, the Sanitary Commissioner concludes with these words, "These people have lived the life of beasts from time immemorial, and they neither know of nor care for any other."

Limited in number as these inspections have been, they have nevertheless removed any obscurity which may have previously existed in Lower Bengal on the subject of local disease causes, and when we place with them the other fundamental fact that the descriptions refer to a vast population spread over the deltas of great rivers, the whole areas of which are either without drainage or are subject to

floods and residual stagnant water, we seem to have arrived at an explanation of the reasons why this great province has obtained the name of the "endemic area" of India, and as regards cholera, of the endemic area whence spreads this pestilence over the world.

57. Apart from all etiological theories we have the evidence of statistical facts, imperfect as these may be, to show the constant elaboration of epidemics within the delta areas, and their great augmentation in severity from time to time, leading, as it were, to overflows from the breeding ground into countries far away from its vicinity. Together with this experience, we have in the present Report a fearless exposure of the local conditions under which the subjects of these epidemics, the people, pass their lives, until increasing predisposition leads to their decimation by cholera or fever, or both, when the next epidemic crop has to be reaped. We have, moreover, the statement that these causes are known and are removable, and that they are not removed, and herein we have the key to the whole Bengal sanitary problem. It is a case of mere *inertia*. The facts are known and admitted by people, medical officers, Sanitary Commissioners, magistrates, and by the Government itself in its resolution on the present Report.

The case is so fully discussed that we scarcely see our way to making any recommendations which do not already exist, in some form or other, in the Report itself.

It would at the same time be unfair not to acknowledge fully the disposition to improve the sanitary condition of the people which the present year's Report exhibits in good work done, and legal powers granted for doing more. But we fear that little of the work touches the core of the question which this and all previous Reports show to lie in the Bengal villages, for it is in them and nowhere else that the epidemic question must be grappled with. If we may suggest any order of procedure, we should feel disposed to advise the cleansing, conservation, and regulation of tanks and wells, filling up of those unwholesome village excavations, removal of local defects in drainage, and the adoption of some rules for village conservancy. All this would be within the sphere of practical work, and could mostly be done village by village, and by the people themselves.

As the Nuddea case has been so fully reported, we would suggest whether special effort might not be directed towards the improvement of this district.

In conclusion, we express our acknowledgments to the reporters who have supplied the materials for this valuable Report, and to Dr. de Fabeck, Professor of Hygiene in the Medical College, Calcutta, who acted as Sanitary Commissioner while Dr. Lidderdale was otherwise engaged.

19th July 1884.

No. 5.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER for the PUNJAB for 1882.

1. The vital statistics of the Punjab for 1882 are based on the census enumeration of 1881, which yielded the following results, exclusive of the population of Khaibar Pass, 8,173 in number, which is not under registration.

The census numbers were, of—

Males	10,210,053
Females	8,640,384
Total	18,850,437

These numbers, which are presumed to yield returns of births and deaths, include the cantonments, but the births and deaths among the cantonment populations are not included in the provincial returns, and hence the ratios are a shade under the truth, but the difference is so small as not to affect perceptibly the year's rates. The cantonment population varies between 200,000 and 250,000. The census population of 1868 was 17,611,498. There was hence an increase of population in the 13 years' interval of 1,238,939.

2. The births registered in 1882 were, of—

Males	371,136
Females	319,388
Total	690,524

The birth ratio was 36·65 per 1,000 living. It was almost the same in urban and rural districts, having been 36·4 in the former group and 36·7 in the latter. The rate for England and Wales for 1876–80 was 35·4 per 1,000. The Sanitary Commissioner says that on the whole he is quite satisfied with the progress which has been made in birth registration, but still there appears to be some explanation required of the fact that the census enumeration of 1881 showed an excess of males over females of 1,569,669 living.

3. Deaths in 1882 were returned of—

Males	271,018
Females	233,781
Total	504,799

The death-rate for males was 26 and for females 27 per 1,000. The provincial rate was 27 per 1,000. Either female deaths are less completely registered than deaths of males, or infant life is more liable to fatality among males.

Similar problems in vital statistics have presented themselves all over India, and they would apparently justify a recommendation that their causes should be investigated.

4. As we now have the population and registration data for the whole province, it may be useful to introduce the following abstract for all districts:—

Districts.	Area in Square Miles.	Population, 1881.	Ratio of Births per 1,000.	Ratio of Deaths per 1,000.	
				1881.	Previous Five Years.
Delhi	1,276	643,515	40·34	31	45
Gurgaon	1,938	641,848	35·90	27	44
Karnal	2,396	622,621	40·99	32	40
Hissar	3,540	504,188	37·25	20	25
Rohtak	1,811	553,609	39·08	26	36
Sirsa	3,004	253,275	34·61	20	27
Umballa	2,570	1,067,263	32·40	27	30
Ludhiana	1,375	618,885	37·51	23	31
Simla	18	42,945	11·20	16	22
Jullundur	1,332	789,555	39·62	24	37
Hoshiarpur	2,180	901,381	37·95	24	31
Kangra	9,069	730,845	30·01	27	27
Amritsar	1,574	893,265	38·50	27	39
Gurdaspur	1,892	823,695	41·66	26	28
Sialkote	1,958	1,012,148	44·73	24	23
Lahore	3,648	924,106	36·89	28	37
Gujranwala	2,587	616,892	43·38	24	29
Ferozepore	2,752	650,519	37·30	22	28
Rawul Pindi	6,218	820,512	34·73	31	36
Jhelum	3,910	589,373	33·71	33	29
Gujrat	1,978	689,115	42·48	21	26
Shahpur	4,691	421,508	41·02	40	27
Mooltan	5,880	551,964	32·89	36	26
Jhang	5,702	395,296	42·36	33	15
Montgomery	5,574	426,529	33·61	23	24
Muzaffargarh	3,139	338,605	41·38	45	28
Dera Ismail Khan	9,296	441,649	30·79	31	23
Dera Ghazi Khan	4,517	363,346	21·37	28	16
Bannu	3,368	332,577	31·31	26	22
Peshawar	2,504	592,674	18·91	17	21
Hazara	3,039	407,075	38·02	24	20
Kohat	2,838	181,540	21·71	12	15
Total for the Province	107,989	18,842,264	36·65	27	30

5. The average population per square mile for the whole province in 1881 was 175, but it varied greatly in different districts. The most sparsely peopled districts were Dera Ismail Khan and Kohat, which had 47 and 64 inhabitants per square mile, and five years' average death-rates of 23 and 15 per 1,000 respectively. The highest density, 2,386 per square mile, was presented by Simla, of which the five years' death-rate averaged 22 per 1,000. Out of 32 districts 10 had densities of population less than 100 per square mile.

6. The census enumeration has enabled the following death-rates to ages to be deduced. They are calculated on the numbers living at each age.

Ages.	Total Deaths.		Ratios per 1,000.	
	Males.	Females.	Males.	Females.
Under 1 year	77,261	67,051	238·56	217·97
1 to 5 years	40,061	43,977	51·14	49·41
5 „ 10 „	12,979	11,152	9·13	9·91
10 „ 15 „	6,911	5,779	5·56	6·29
15 „ 20 „	5,594	5,098	6·17	6·89
20 „ 30 „	16,617	16,212	9·08	10·51
30 „ 40 „	16,512	15,573	11·98	13·33
40 „ 50 „	20,830	15,980	20·73	18·46
50 „ 60 „	26,992	14,664	31·60	28·12
60 and upwards	46,261	38,295	78·27	78·46

We learn from this table that out of 692,534 children born in 1882 there were 144,342 deaths under one year of age, and that under five years 236,350, or about 34 per cent. of those born, had died.

7. The population, deaths, and death-rates among different classes were as follow:—

Classes.	Population.	Deaths.	Death-rates per 1,000, 1882.
Mahomedans	10,522,802	286,315	27·21
Hindus	8,288,575	177,029	21·37
Christians	32,500	37	Ratio uncertain.
Other castes	3,387	41,418	—
Total	18,842,264	504,799	26·79

It will be seen that the deaths of "other castes" greatly outnumber the population, because the local registrars have included in the column of deaths those due to Mahomedan and Hindu sweepers, a classification referring to occupation rather than to class. This will be rectified in future.

There are in the Punjab 28,677 Europeans and Eurasians, among whom registration appears to require looking after, as the recorded birth and death rates amounted in 1882 to 3·56 per 1,000 and 3·06 per 1,000 respectively.

8. The death-rate divided between the population of 32 country districts and 49 towns gives the following results:—

Population.	Death-rates per 1,000.	
	1882.	Five Years' Average.
Districts, 17,512,378	26	29
Towns, 1,310,383	33	47

Both ratios show improved health.

9. *Death causes in* 1882.—The following were the registered causes of death under the usual headings:—

Diseases.	Total Deaths.	Deaths per 1,000 of Population.
Cholera	39	0·002
Small-pox	6,379	0·340
Fevers	346,674	18·400
Bowel complaints	15,965	0·850
Injuries	4,753	0·300
All other causes	129,989	6·900

10. The year's disease history presents some points of considerable importance which require notice. The Sanitary Commissioner has given a chart showing the monthly prevalence of cholera since January 1867, of which the following figures are the annual totals:—

Years.	Deaths from Cholera.	Years.	Deaths from Cholera.
1867	43,146	1875	6,246
1868	532	1876	5,736
1869	9,258	1877	29
1870	469	1878	215
1871	369	1879	26,135
1872	8,727	1880	274
1873	148	1881	5,207
1874	78	1882	39
Totals	62,727	Totals	43,881

This abstract gives the statistical history of Punjab cholera for a period of 16 years, and one result follows from the facts, namely, that up to the present time we have no means of accounting for them.

No theory of cholera germs, cholera poison, personal contact, commercial intercourse, railways, insanitary surroundings, bad water, or climatic peculiarities throw the smallest light upon the facts.

The intensity and fatality of the disease in each year is governed by some other factor, and this mere waste of time and effort to try to explain them on any series of suppositions, however plausible these may appear to be, while it is positively injurious to the best interests of the public health to assume that because some one thinks that he has observed a distinct case of causation, therefore this case can be usefully made to include all other cases, whether a cause was or was not observed.

We can, however, from the facts as they stand, deduce certain important practical lessons. The years 1867 and 1879 were Hurdwar fair years, but they were also years of severe cholera prevalence in regions of India beyond the fair influences. The assemblages at Hurdwar involved added insanitary factors of well known evil repute under such circumstances, namely, fatigue, crowding, filth, impure water, and waning excitement, and no doubt the Hurdwar fair years show the highest death-rates in the series. Hurdwar itself presents considerable local difficulties to the sanitary improver, and as the conditions depend to a large extent on local topography, the question to be solved in any given case is, whether the site admits of being kept in a wholesome condition with a great crowd of pilgrims and animals. If this cannot be done, the advent of cholera in an epidemic year may be anticipated, and this presumption points to suspending the fair, or to limiting the numbers resorting to it. But while saying this, it must be stated that holding of fairs at Hurdwar has been quite safe with limited numbers and efficient sanitary work.

Now, all this can be done without complicating the work of civil officers by the introduction of hypothetical causes, which up to the present time have not been proved to exist, far less to be efficient.

Another important lesson taught by the table is that the mortality from cholera, which in the first eight years of the series had been 62,727, had declined during the second eight years to 43,881, showing apparently the influence of sanitary work on the mortality. But the law of cholera prevalence which is of most practical importance is the great oscillation in cholera mortality, and, as our only known means of coping with this feature of the epidemic is cleanliness and pure water, these should be strenuously pursued during seasons when mortality is lowest, so as to diminish the risk of increase when the years of greater epidemic intensity come round.

11. We shall next show the relation which existed between the Hurdwar fair of 1882 and the Punjab cholera of the same year. And first, the following abstract shows the monthly deaths from this disease in 1882:—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
January	3	July	8
February	5	August	6
March	2	September	4
April	3	October	8
May	6	November	1
June	2	December	1

All cholera deaths of the year were recorded in 28 registration circles out of 446 in the province, and only 30 villages out of 34,973 furnished the whole mortality.

Hurdwar fair was held between the 6th and 16th April, and was attended by 100,000 people, the daily average having been 60,000. Every care was exercised to preserve the whole locality of the fair free from impurity, and ample provision was made for the immediate discovery and treatment of premonitory cases. The Sanitary Commissioner of the North-West Provinces and the civil officers were on the spot to see that nothing was neglected. There was not a single case of cholera due to the fair or in its neighbourhood, and, as the table shows there were only three deaths from cholera in the Punjab during the fair month. Experience, therefore, leaves us with the following results, so far as the fair is concerned:—1st, the best attainable sanitary arrangements for 100,000 pilgrims; 2nd, a moving cholera of low intensity; 3rd, complete immunity of these pilgrims from cholera. There was only one choleraic case in a pilgrim apparently imported.

12. In 1882 cholera first appeared in the vicinity of Delhi in January, and moved in a north-west direction. We had thus the presence of cholera and its movement in time and space, and the fair was held close to the line of movement. The one circumstance which distinguished this cholera was its very low intensity, as shown by the small number of deaths, but the disease was there, and ought to have spread in conformity with "germ" or "contagion" law had these been the only factors in the case. Sanitary defects and impure water sources in towns and villages were the same as they had been. Why then was there so little cholera in the province? This question is far too important to be replied to by putting forward any theory. The reply must either be a fact or a confession of ignorance. So far as the actual data lead us, all we can say is that they belong to a class of which the experience has been constant. It needs no further proof to show that the history of Punjab cholera has been one of cyclical increase and diminution connected with the greater or less number of population groups attacked, and with the greater or less number of deaths in each attacked group. This is the historical fact, and as we know, from very large experience, that cleanliness and pure water are the main practical steps at our disposal for diminishing the number of local attacks in all stages of intensity, we arrive again at the practical conclusion that sanitary work should be at all times depended on as the real protection against epidemic cholera anywhere. The mere facts of the case show that cordons and all similar quarantine measures are quite useless, simply because in a country subject to epidemics these diseases are behind as well as before any possible line of cordons,

and cordons presuppose passage of people from affected to unaffected centres at specific times, an event of very rare occurrence. But the great danger of trusting to cordons for protection lies in the fact that the only known means of protection, sanitary measures, are neglected or set aside, and our most recent experience, that of the affected towns in Egypt, has taught us with what results, for even at the last moment people were shut up on polluted town sites to perish by hundreds, instead of being removed bodily away from them as the only present means of saving life. The people perished in obedience to a theory.

13. *Small-pox.*—Epidemic small-pox is a far more formidable and fatal disease in the Punjab than cholera has been. This is well shown in the following abstract of a chart given by the Sanitary Commissioner in the present Report :—

Years.	Deaths from Small-pox.	Years.	Deaths from Small-pox.
1868	23,759	1876	10,254
1869	53,195	1877	12,296
1870	27,163	1878	40,271
1871	25,534	1879	49,489
1872	23,728	1880	9,145
1873	25,699	1881	6,749
1874	12,026	1882	6,379
1875	13,594		

LIBRARY OF THE BOMBAY BRANCH. OF THE ROYAL ASIATIC SOCIETY.

Comparing the same 15 years, 1868—1882, for the two diseases, the deaths have been as follows :—

Cholera	63,462
Small-pox	339,281

For every death from cholera there have been upwards of five deaths from small-pox within these years. It is, however, satisfactory to find that there has been a considerable reduction of small-pox mortality of late years, for, if we divide the 15 years' data into two periods of 7½ years each, the table shows that in the first period the deaths amounted to 197,901, and during the second to 141,380, showing a saving of 56,521 lives. It will be observed also that the return for 1882 shows the lowest mortality of the series. The great outburst of small-pox in 1878–79 corresponds to the famine augmentation of small-pox mortality in Southern India.

The next abstract shows the monthly deaths for 1882.

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	358	July	744
February	334	August	568
March	408	September	286
April	682	October	165
May	896	November	207
June	1,104	December	728

Of 32 registration districts, Simla alone returned no small-pox deaths. Out of 446 registration circles, 297 registered deaths, but when we come to the villages the usual anomaly is presented of all the deaths having taken place among a few groups of population only. There are 34,973 population groups, of which 1,777 yielded all the small-pox mortality.

Of 49 towns, having a population of 1,310,383 persons, 32 returned 1,743 deaths, or 1·33 per 1,000, while the country circles, including 17,512,378, returned 4,635 small-pox deaths, a rate of 0·26 per 1,000. The conjoint rate for the whole province was 0.34 per 1,000.

14. *Vaccination service.*—Within the last year or two the vaccination service in the Punjab has been reorganized, and the work is now carried on by district, special, and cantonment vaccinators.

The district staff in 1882–83 included 27 supervisors, 40 first-class vaccinators, 67 of the second class, and 149 of the third class.

The total primary vaccinations performed by this staff were 464,886, and of re-vaccinations 2,331. Of primary vaccinations 442,315 were successful, and of re-vaccinations 1,070.

Vaccinations performed by the special staff numbered 29,507, of which 27,912 were successful. Of re-vaccinations, 274 in number, by this staff, 118 were successful.

In cantonments 2,407 individuals were primarily vaccinated, of which 2,296 were successful, and of 292 re-vaccinations 216 succeeded.

The year's returns were not complete at the date of the Report, but a sufficient idea of the year's work and its probable influence on small-pox mortality may be obtained from the following summary :—

Total year's births	690,524
Total small-pox deaths	6,379
Of these under one year	1,481
Total successful primary vaccinations	472,523
Of which under one year of age	354,414

More than half the children born were vaccinated, which, under the circumstances, was good work, and it will be seen that 76·4 per cent. of the small-pox mortality of the year took place at ages exceeding one year. The data are, of course, limited to one year, but, with so large an amount of vaccination work in hand, we should naturally expect considerable saving of infant life.

This subject is otherwise of a departmental character, and very full details are given about the year's proceedings.

15. *Fevers.*—In 1882 no fewer than 346,680 people died of fever in the Punjab. The fever death-rate was 18·50 per 1,000, less, however, than the previous five years' mean, which was 20·77 per 1,000.

The annual fever deaths for a period of 15 years, as given in the fever diagram, have been as follows:—

Years.	Fever Deaths.	Years.	Fever Deaths.
1868	151,337	1876	351,286
1869	272,946	1877	219,231
1870	275,093	1878	440,492
1871	213,548	1879	472,939
1872	264,711	1880	322,727
1873	219,909	1881	355,279
1874	190,631	1882	346,680
1875	279,825		

The mortality from cholera and small-pox are small matters when compared with the figures in this abstract. The two years of highest mortality, 1878, 1879, were years of scarcity and high food prices, but, even disregarding these two years, it is evident that deaths registered as due to fevers have largely increased of late years.

In 1882 every district in the Punjab returned fever deaths, and all the registration circles, 446 in number, registered fever deaths, with a single exception in Hazara district. But nothing can show more clearly the universality of fever than the fact that, out of 34,973 population groups, 28,818 suffered.

The fever death-rate in the country circles was 18·50 per 1,000, and in the 49 towns it was 17·14 per 1,000.

Fever death-rates exceeding 20 per 1,000 were registered in the following districts:—

Districts.	Fever Deaths per 1,00 of Population.
Karnal	20·89
Jhang	22·15
Rawul Pindi	23·62
Dera Ghazi Khan	24·81
Dera Ismail Khan	25·08
Jhelum	25·68
Mooltan	27·60
Shahpur	28·47
Muzaffargarh	37·95

Similar differences showed themselves in the town registration. In 11 towns the fever death-rates exceeded 20 per 1,000.

In Find Dadan Khan, out of a population of 16,724, there were 672 fever deaths, and in Bhera 816 died out of a population of 15,165. In the former town the fever death-rate exceeded 4 per cent., and in the latter 5 per cent. of the population.

16. The incidence of fever mortality by months was as follows:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	27,661	July	18,202
February	19,093	August	21,480
March	20,129	September	31,634
April	18,656	October	42,293
May	23,046	November	51,269
June	22,642	December	50,619

In discussing the climatic causes of fevers in the province, the Sanitary Commissioner has given tables and diagrams to show the relation of fever mortality to rainfall, but as the aggregate fall at all the observing stations, both for months and years, is used in the comparison, the results are scarcely of a very exact nature.

The number of annual fever deaths does not always correspond with the aggregate rainfall of the years, neither do the monthly fever deaths correspond with the monthly aggregate rainfall; but there

is an important general feature, which recurs year after year, and thus establishes a relation between rainfall and fever mortality, and it is this. The great rainfall in each year begins in July and lasts through August and into September, after which there is not much rain, but there is drying up, accompanied with variable temperature and cold. In September the fever mortality suddenly rises, and continues high till the end of the year and into the month of January of the year following. The large increase of rain in July does not augment the fever mortality of that month, but its effect is obvious enough in the subsequent months.

Reverting to the preceding abstract of monthly fever mortality, it will be seen that during the first six months of 1882 there were 131,227 deaths, and during the last six months 215,453 deaths were registered. During the first six months the aggregate rainfall at all the observing stations was 119·4 inches, figures which are only useful as affording a means of comparison. In the next three months, July, August, and September, the great rainfall of the year took place, yielding the high aggregate of 646·1 inches. As a matter of fact, the rainfall in these three months was nearly 5½ times the amount which fell in the first half of the year, and the fever deaths were 71,266. During the last three months the entire aggregate rainfall was only 2½ inches; in other words it was *nil* so far as regards fever, but these were the drying up and variable temperature months, and they yielded 144,187 fever deaths. These facts, recurring year after year, as the Sanitary Commissioner has shown that they do, lie at the foundation of fever etiology in the Punjab.

Districts and population groups along the course of rivers suffered most from fever in 1882, due to rise in the water-level, flooding, back-watering of the subsoil, and consequent reproduction of marshy malarial conditions.

In the case of Pind Dadan Khan, with its 4 per cent. fever death-rate already mentioned, "the "water came up round the city, and entered the streets and lanes, in some places to a depth of "over two feet. All the low ground from Jhelum along the river was swamped, and fever necessarily "supervened."

The five per cent. fever death-rate at Bhera arose from a similar cause. The loss of life was due entirely "to heavy and repeated floods caused by repeated freshets in the Jhelum river, which "inundated the district, and, when the water receded, swamped all the low localities which surround "most Indian villages and towns, leaving marshes and hollows full of green water. These floods "have also brought the springs to a high level, and the sun still being warm in the day, the mornings "and evenings are cold. And these sudden changes, together with the air being charged with "malaria, is (in the opinion of the Deputy Commissioner) the chief cause of this serious outbreak of "fever, from which neither Europeans nor natives have escaped."

There appears to have been no scarcity of food to aggravate the liability to fever, and Europeans also suffered. Generally, food prices appear to have been lower than of late years.

The whole subject appears to have been fully inquired into by order of the Government, especially in the flooded districts, where, from local circumstances, there were added fever causes beyond those from which the province suffered as a whole. It is important, however, to quote a fact stated by one of the deputy sanitary commissioners, who says that in one village where there was fever the flood did not come within two miles of it, while the fever broke out simultaneously over a large tract of country, but "the severity of the outbreak was directly proportioned to the floods."

17. The fever was simply malarial fever chiefly quotidian, in some cases attended by vomiting and purging. The fever usually lasted from 7 to 10 days.

The registered fever deaths in 53 villages for August, September, October, and 25 days in November afforded the following interesting facts:—

Deaths.

Males	299
Females	318
Total	617

Ages of Death.

1 year and under	298
2 to 5 years	115
6 to 20 years	42
21 to 49	48
50 and over	114
Total	617

About 67 per cent. of the total fever mortality took place at and under five years of age, and 98 of these deaths took place in infants at and under one month old.

Facts of this class point not only to the influence of malaria in causing fever, but to the effect of predisposition or liability to attacks manifested in infant life, and due to a large extent to want of suitable clothing, protection, and care at susceptible ages. The case, as a whole, is well put as follows. Referring to a district which suffered severely, the Deputy Sanitary Commissioner says:— "Everywhere in the area traversed I found the existing causes of the prevailing sickness to be in a

" change of the climate produced by inundations and water-logging of the soil in the river valley, " rendering the air of the country unusually damp, and subject to chills with the alternation of night " and day temperature, whilst the predisposing causes were due to the defects in the sanitary sur- " roundings of the people and to unfavourable conditions in the material prosperity of the labouring " classes, mainly in respect to their being altogether insufficiently clad, and in respect to their poverty " rendering them incapable of improving this unfavourable condition without aid of a charitable " kind."

18. The insanitary surroundings of the people referred to are those usually found among Indian village populations, and consist of unremoved village filth, and contaminated water as a consequence of it. The Deputy Sanitary Commissioner says: "Without exception, I found all the villages visited in my tour in a very filthy and neglected state of conservancy;" and he advocates the introduction of village conservancy rules in this district. This, of course, can be done, and should be done at once. There is now no reason why every village in the province should not be once for all cleansed, and afterwards kept clean.

In districts liable to periodical flooding, the only remedy must be found either in removing the population beyond the influence of the water, or, in local drainage works, to relieve the surface and subsoil of water as quickly as possible when the river falls. Fever is sure to follow if there are places where the flood-water has to remain until it is dried up by evaporation.

The practical conclusion stated by Mr. Bellew appears to include the main principles to be kept in view in dealing with these fevers. He says:—"The cause of sickness and death from these malarious " fevers is, to a great extent, preventible by an efficient drainage of the soil and precautions in the " matter of habitation, clothing, and food. In proportion as these matters are attended to, and " exposure to 'chill' provided against, not only by the adoption of suitable sanitary measures for the " welfare of the general community, but also by attention on the part of the individual to ordinary " precautions of personal protection from exposure to this most common cause of sickness in such " localities, namely, to 'chill,' the result of exposure in an unprotected state (whether from unsuitable " clothing, faulty housing, or deficient food) to the alternations of temperature and humidity in the " course of night and day, so will the rates of sickness and death diminish."

One practical result of the experience is that cheap and suitable clothing is nearly as much required to enable a population to bear up against malaria and its fevers as is cheap and suitable food. Better drainage, improved agriculture, better housing (which might very well be made an object by the Indian sanitary service), strict attention to cleanliness and keeping clean, good water, cheap clothing, and cheap food, include the remedies of which Government might take cognizance in the general administration of the country. They all form part of the great end of all government, namely, improvement and civilization of the people, which includes under it the prevention of disease.

19. Intimately connected with the relation of natural flooding to fever mortality is the relation which fever mortality bears to irrigation, which is in reality artificial flooding, because the essential fever-producing condition in both cases is water-logging of the subsoil and consequent stagnation.

But irrigation is so intimately related to the food production in certain districts, that there has been a not unnatural disposition to doubt this view of fever causation, and the Government of India in 1875 directed a special statistical inquiry to be made into the death-rates in irrigated districts close to the West Jumna Canal. For this purpose 25 villages, with a population of 27,983, were selected in Delhi district, and 23 villages, with a population of 15,153, in Karnal district.

The results for four completed years have been as follows:—

	Death-rates per 1,000.			
	1879.	1880.	1881.	1882.
Delhi Villages - - -	65	47	58	46
Karnal Villages - - -	76	44	41	37

These rates are very high, and greatly exceed the average for the province, which was 27 per 1,000 in 1882, and 29 on the previous five years' average.

The following was the average death-rate of both groups of villages for the same years from fevers:—

Population.	Fever Deaths per 1,000.			
	1879.	1880.	1881.	1882.
43,136 - - - -	54·4	35·8	37·7	31·

These fever-rates also compare unfavourably with the average rate for the whole province for 1882, which was 18·40 per 1,000, and 20·77 per 1,000 for the previous five years. The inquiry is still incomplete, but the result is against irrigation without drainage.

20. *Bowel complaints.*—Deaths registered under this title are chiefly diarrhœa and dysentery, the mortality from which in 1882, namely, 15,960 deaths, was the smallest hitherto recorded. During the last 15 years "bowel complaints" have yielded the following annual mortality:—

Years.	Bowel Complaint Deaths.	Years.	Bowel Complaint Deaths.
1868	17,828	1876	27,271
1869	30,953	1877	17,664
1870	27,249	1878	32,071
1871	21,678	1879	29,612
1872	28,345	1880	20,736
1873	19,640	1881	17,281
1874	16,407	1882	15,960
1875	27,550		

Deaths from "bowel complaints" were registered in all the districts and in all the towns of the Punjab in 1882; also in all registration circles, 446 in number, with 28 exceptions. But, as usually happens, only a limited number of population groups (5,045 out of 34,973) returned deaths under this head. The death-rate was 0·85 per 1,000 against a previous five years' average of 1·34 per 1,000. It was highest in the towns, viz., 2·46 per 1,000. In the country districts the rate was 0·72 per 1,000, showing either better registration in the towns or more powerful local disease causes, probably the latter, as the town death-rates vary far more among themselves than the country rates. The lowest town rate of the year was at Lahore, namely, 0·58 per 1,000, and from this ratio the proportions mount up until the highest rate, 5·26 per 1,000, is reached at Palwal.

The lowest country rate was 0·18 per 1,000 at Peshawar; the highest, 2·48 per 1,000, was at Simla. Only four district rates exceeded one per 1,000.

The monthly distribution of bowel complaint mortality for the whole population was as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	1,074	July	1,158
February	726	August	1,609
March	814	September	2,019
April	954	October	1,878
May	1,366	November	1,660
June	1,137	December	1,565

The deaths were most numerous during the second half of the year, but culminating in September, when heat and moisture after rain were present at the same time.

21. *Injuries.*—Under this denomination were recorded the following violent deaths:—

Suicides:

Males	126
Females	181
Total	307

Of these deaths 121 were from drowning, 114 from hanging, and 26 from poisoning by opium. The district of Gurgaon furnishes the largest number of suicidal deaths. It is stated that "on the slightest provocation" the women in this district are prone to throw themselves into wells.

Accidental deaths numbered 3,965, of which 2,080 were from drowning. Deaths from snake-bite were 1,014. There is a tendency to increase in this death cause, as may be seen from the following annual numbers of snake-bite deaths:—

Years.	Deaths.
1877	830
1878	752
1879	818
1880	968
1881	1,012
1882	1,014

The proportion of deaths from this cause differs greatly in different districts.

This is shown by a five years' table for all districts, which has also a column showing the total five years' death-rate per 100,000 from snake-bite. The lowest five years' rate was 0·7 per 100,000 for Peshawar district. The following districts gave the highest rates:—

Districts.	Total Five Years' Ratio of Deaths from Snake-bite per 100,000.
Lahore	9·8
Jhang	10·6
Shahpur	10·7
Montgomery	11·7
Muzaffargarh	12·4
Gujranwala	13·6

The Government is fully alive to the facts, and points probably to the true cause, namely, that the rewards which have been sanctioned by the Supreme Government are too small (two annas per snake). The work is a hazardous one, and should be paid for accordingly. Coloured models of all the poisonous varieties have been furnished to every tahsil and thana. The high death ratios recorded above show where the destruction of poisonous snakes ought to be most actively carried on.

Deaths from hydrophobia appear to be increasing in the Punjab, as the following numbers show:—

Years.	Deaths from Hydrophobia.
1879	69
1880	107
1881	139
1882	128

A remedy is evidently needed for this evil.

Of deaths by wild beasts 20 were by jackals, 10 by wolves, six by scorpion stings, five from boars, and three from bears.

22. *All other Causes.*—There were 122,989 deaths so registered in 1882, but an attempt has been made by the Sanitary Commissioner to introduce some order into this classification, and the results have been well worth the trouble. He has been able to extricate 29,645 deaths out of the general confusion, and to class them under the head of cough and chest diseases.

The following table gives the numbers for two years:—

Months.	Deaths from Chest Diseases.	
	1881.	1882.
January	3,518	3,008
February	3,435	2,534
March	3,185	2,677
April	2,497	2,007
May	2,142	2,428
June	1,800	1,938
July	1,608	1,680
August	1,890	1,810
September	2,510	2,063
October	2,792	2,308
November	2,699	2,914
December	2,828	4,283

We now know approximately that chest diseases caused a death-rate of above 1½ per 1,000 of the entire population of the Punjab in 1882, although there is reason to suspect that the rate was much higher.

The above table shows that the dry warm months are attended by the lowest mortality, and that the death-rates rise during the wet, damp, cold, and variable seasons. The information, imperfect as it may be, is a real gain to the sanitary history of India.

23. Before concluding the disease history of the year, the following statistics may be here introduced. Four hill sanitaria, Simla, Dharmsala, Dalhousie, and Murree, gave the following death-rates in 1882:—

Total population, 19,503.

Diseases.	Deaths.	Deaths per 1,000.
Cholera	—	—
Smallpox	1	0·05
Fevers	180	9·2
Bowel complaints	60	3·6
Total deaths, all causes	443	23

The birth-rate was 10 per 1,000, and the death-rate 23 per 1,000, in part due, no doubt, to invalids at the stations.

Cantonments.—There are 33 cantonments in the province, having a population of 206,689, among which the following deaths were registered in 1882 :—

Diseases.	Deaths.	Deaths per 1,000.
Cholera	—	—
Smallpox	7	0·03
Fevers	1,651	7·9
Bowel complaints	186	0·6
Total deaths, all causes	2,873	14·

The death-rate, 14 per 1,000, was not high, but it will be observed that nearly 8 out of the 14 per 1,000, above a half, was due to fevers.

Lawrence Military Asylum at Sanawar.—This establishment contained 239 boys and 182 girls in 1882, and out of 421 inmates there were 2 deaths, or 4·7 per 1,000. One of the deaths was due to enteric fever in a boy.

Lawrence Memorial Asylum at Murree.—Out of 90 boys and 68 girls there was no death in 1882.

At Sanawar, the total sickness of the year was represented by 505 admissions, of which 2 were from enteric fever, 4 from simple continued, and 11 from paroxysmal fevers.

At Murree there was no enteric fever. There were 2 cases of simple continued, and 3 of paroxysmal fevers.

At neither establishment was there any epidemic disease.

24. *Sanitary Works (Civil).*—In the 32 districts of the Punjab there are 201 municipal towns, from which returns of income, expenditure, and work done in 1882 were received. Their total population is not stated. At the beginning of the year they had an unexpended balance of 108,899*l.* Their actual income for 1882 was 289,538*l.*, making a disposable total of 398,437*l.* Of this amount there was expended 291,302*l.*, and an unexpended balance of 107,135*l.* was carried forward. It will be observed that the expenditure of 1882 slightly exceeded the actual income of the year.

The outlay for sanitary works was as follows:—

	£
1. Conservancy establishment	41,627
2. Paving	7,405
3. Roads and bridges	25,742
4. Drainage and sewerage	17,763
5. Water-supply	12,279
6. Widening streets	3,523
7. Construction of latrines	1,269
8. Repairs of latrines	772
Total	£110,325

The amount is small, but it is satisfactory to see that so large a proportion of it was devoted to the cardinal improvements in conservancy and water supply. Details of works carried out under these heads of expenditure are given, but they merely reproduce the measures adopted under the expenditure heads in different districts, and convey little additional information, except to show that the work was done.

One satisfactory point in the district reports is that the use of town sewage as manure is rapidly increasing, and that considerable sums are being realized by its sale. It is a matter of great importance that the practice should be extended, because, amongst other advantages, it facilitates the immediate removal of household sewage from the houses and village sites. We are glad to see it stated that, in 60 villages in Karnal, manure yards have been established outside their bounds, and that manure depôts for towns are also being provided.

25. There are a few points in the town reports to which attention might very well be called. There is a proposal for removing the sewage of Simla, which is described as follows:—"The sewage from "the main bazaar, as well as from Chota Simla and Boileaugang, will be carried in iron pipes into "the ravine south of Simla." Plans and estimates have been prepared for the work, and it was "in "contemplation to improve the house drains in the bazaar by insisting on owners of houses and "shops using iron pipes of an improved pattern." So far, there appears little to object to in an elementary proceeding such as this is. But in a letter on the subject from the Commissioner of Umballa division the following objections are raised. He says:—"I entirely agree with Major Nisbet's "plan of carrying the night-soil away by hand in iron buckets or *kiltas*, and depositing it in depôts "from which it is to be carried in iron pipes down the hill, but where Major Nisbet proposed, and I "believe this is the plan now before the committee, to carry the night-soil by the pipes down into "the ravines, notably the waterfall ravine. This plan utterly ruins the most beautiful part of Simla

" a stream so beautiful that if it were in Wales or Cumberland a railway would be made especially " to take tourists to see it. This, however, is the least of the objections. It runs great risk of " making the waterfall valley and the river further down permanently unhealthy; and, lastly, it is a " sad misuse of valuable material."

And he purposes, instead of this method, to carry the night-soil in pipes down to the lower spurs, and there trench it.

The ravine where it is proposed to discharge the filth is south of Simla, and, on turning to page 13 of the report of the Sanitary Commissioner with the Government of India, we find it stated by Mr. Blanford, in his meteorological summary for December 1881, that " at the hill stations of the " North-Western Himalaya there was the same striking and anomalous preponderance of west and " south-west winds as in the previous months."

It is a well known fact in regard to these hill stations that the practice of depositing filth and sewage in the ravines is a cause of epidemics among the inhabitants. This arises from foul and pestilential emanations being carried up the ravines by ascending air currents, which, in the present instance, would apparently be intensified by the west and south-west winds. The plan is nothing more than the one which was long ago adopted in Calcutta and Bombay, where it is still carried out, with this important difference, however, that the sewage is discharged now at points where it can do no harm. It must also be remembered that troops and other occupants of these hill stations go down into the ravines and suffer in health from the foul vapours in them.

In the present case the beautiful valley and waterfall may be converted into an epidemic trap by this proposal. There can be no question whatever that the only safe way of disposing of the sewage of Simla is to trench it at points as nearly as can be obtained to leeward of the station by whatever method it may be conveyed, and if trenching is the method that must be adopted.

26. *Amritsar.*—There are two statements about the drainage of this city which appear to require some explanation. One of them is as follows :—" The project for the intramural drainage is also in " hand. The city sewage will be conducted into the ditch round the city, which has been deepened " 9 feet to admit of a proper flow from all connected sewers, and from it will be conducted in an " egg-shaped sewer to settling tanks to be constructed at about 3,500 feet from the city walls, where " the solid contents will be allowed to settle, and the liquid to flow away into the system of extramural " drainage." The other statement on a subsequent page is as follows :—" The main drain is nearly " complete, and the internal drainage of the town is constantly being improved. The filling in of " the city ditch has seriously been taken in hand by the municipal committee." It is not clear whether the ditch referred to in the two passages is the same. And we must hope that in the first passage it is not intimated that the catch water sewer for the city sewage is to be merely a deepened city ditch, and not a properly built and covered up sewer. Ditches of this kind ought never to be used for outfalls.

27. The only other remark which appears to be called for under this heading is, that a considerable amount of good surface work appears to have been done in the 49 Punjab towns in 1882, and we may conclude these remarks on this section of Mr. Bellew's report, by the mortality statistics as follows, for these towns :—

Population 1881	-	1,310,383
Death-rate all causes in 1882	-	33 per 1,000
Death-rate, previous 5 years' average	-	47 "
Difference	-	14 "

The present rate is still too high, but there is no reason to call in question that the rate has declined, especially as registration is improving, and consequently a larger proportion of deaths is registered each succeeding year.

28. *General Remarks and Personal Proceedings.*—Under this heading, which forms Section X. of the report under review, are given some interesting particulars about the year's inspecting work. The civil surgeons in the course of their tours inspected 80 towns and 178 villages in all the 32 districts of the Punjab. Similar work was done by vaccination officers, but there are numerical data only from 20 districts, in which, however, no fewer than 14,211 villages and towns were inspected and reported on, and in many of them improvements were carried out.

This department of the work is only in its infancy, but nevertheless work of some kind has been done, the people are being taught the importance of local cleanliness, and village authorities are becoming more alive to their duties. A few extracts from the civil surgeons' reports will show how this inspecting work is proceeding.

The Civil Surgeon, Karnal, trained his vaccinators for sanitary work. He found that village lambardars would not listen to the vaccinators unless their suggestions had received the approval of district officers. The tahsildars were then requested to help vaccinators, who thereafter proceeded with their work of inspecting and reporting, and they framed maps to show what were their proposals; these were authorised by the civil surgeon and returned to the tahsildars for execution. But the result was simply opposition. "In many cases the lambardars and zamindars objected, their reasons " being innumerable; then often when these individuals had agreed, the chamars or sweepers of the " villages would object, and submit to me a petition begging of me to remove the site (for depositing " filth and sweepings) to some other spot." The chief cause of objection in such cases was the distance of places of deposit, but this difficulty was overcome by the personal influence of the civil

surgeon. There was a disposition shown to revert to old filthy practices, a matter not to be wondered at after ages of neglect of ordinary sanitary precautions, but there were signs of this disposition having yielded to perseverance and reason, and the reporter says:—"On the whole, however, I think that a great deal can be done by perseverance, and I am quite certain that a great "many of the villages that came under the sanitary work last hot weather are patterns of cleanliness "as compared with those that were not inspected by the vaccinators." So far, then, work has been done, but the difficulty does not lie here, it lies in the keeping up of continuous cleansing, and a proposal is made to effect this object by punishing the officials of neglected villages.

Apparently what is wanted is a common nuisance law, under which "the lambardars should be made responsible for the sanitary condition of their villages," and subject to the usual penalties for default. So far as the experience has gone it shows that some such course is requisite. The objects to be aimed at are initiative and persistence in the work after it has been commenced, and if means are provided for this purpose, the vaccination officers might do the rest by local inspections and advice to the people and village officials, without trying to enforce orders, which in some cases they appear to have done. But even as the case stands there is reason to believe that these periodical inspections are doing a considerable amount of good among village populations.

29. Much more is being done in towns and districts under municipal and district committees, especially in the important matter of cleanliness. The Sanitary Commissioner states that "a great "deal of practical work in the way of improving the sanitary condition, especially with regard to the "monopoly of town sweepings and filth by the municipal committees, has been effected. In the case "of several towns in which the town refuse was regularly stored and systematically disposed of as "manure for fields, and fuel for brick-kilns, there has been not only a marked improvement in the "general cleanliness of the town area, and this without any extra expense, but, so far as statistics "prove, in their healthiness also." . . . . "In the case of towns there can be no question of the "advantages of an improved system of conservancy under the careful supervision of municipal "authorities. The great difficulty is in the way of improving the sanitary condition of villages." Does not this experience prove that what is wanted for the villages is simply a sanitary authority and executive? The people are the same in either case. The towns are only a little more populous, some of them scarcely more populous than the villages.

Of Sirsa district, the Deputy Commissioner says:—"As long, however, as we have no compulsory "powers, such as those levying special conservancy taxes, our efforts must necessarily be confined to "moral suasion." This is apparently true, but as we long ago insisted on, the things to be done ought all to be done by the people themselves, simply because every household can do all that is required for protecting its health by cleanliness, and preserving its water-supply from pollution. Spade labour could be used for levelling, filling up holes, and surface draining. Cattle can be kept within village limits, where they would do no injury to health if properly attended to; roads, lanes, and house compounds can be kept clean. These things could be required from all village populations and village officers, under fines for non-compliance. But if the people prefer to have the work done on a general village plan, there would be no hardship in calling on them to pay for having it done for them. There are several cases mentioned in the district reports in which the required steps had been taken by the people under pressure from the village officers, and it would almost appear as if these officials held the key of the position, and that the work might be done by holding them directly responsible for it.

In reference to this stage of the work it may be stated that brief abstracts are given by the Sanitary Commissioner of reports from all parts of the province, from which it appears that much was being done in many localities to give effect to recommendations made by inspecting officers.

So far the results, if not altogether satisfactory, have been at least hopeful for the future.

It is stated that "in the matter of sanitation the Bagars rank first, the Sikhs next, and the Mussal-"mans last. The principal offenders against sanitary laws are the women, who are too indolent to "remove their house refuse to a proper distance from the village." In such cases a cleansing tax might be of use.

30. *Inspection Reports.*—Under this head is given a summary of reports on towns and villages, prepared by the Sanitary Commissioner, and a similar summary of inspection reports made by Deputy Sanitary Commissioners, and by civil surgeons.

Mr. Bellew's reports refer to inspections made by him during the cold season of 1882, in Amritsar, Dera Ismail Khan, Bannu, and Kohat districts. The summaries give a general account of the topography, towns, vaccination, and sanitary works and measures in each district. The facts are of the usual character, and do not require comment, but a few points may be noticed. In Amritsar town the streets were remarkably clean and wholesome, a result which has been effected by the introduction of tramways for the removal of filth and refuse, and the Sanitary Commissioner advised their adoption for Lahore and Delhi, where they would afford great advantages over the native method of dealing with such matters. The municipality had under consideration a proposal for filling up the Santokhsar tank, and converting it into a garden, a work which Mr. Bellew says is "highly to be commended for the sanitary advantages associated with it." There are other tanks in Amritsar, and many other towns which might be similarly dealt with very advantageously for the interests of the public health. The outfall sewers had been completed. The general sanitary condition of the city was satisfactory, but much remains to be done before Amritsar is safe from fever epidemics. Its five years' death rate had been 72 per 1,000, which in 1882 had fallen to 41 per 1,000, and of this high rate 22·26 per 1,000 was due to fevers.

Dera Ismail Khan.—A great deal has been done by Deputy Commissioner Major Macaulay for the improvement of this town. "Altogether the town bore a very clean, prosperous, and wholesome appearance," but conservancy required to be carried beyond the principal streets into the lanes and

compounds, and drainage was required, as is shown by the great fever death-rate, 28·39 per 1,000, out of a total death-rate of 45 per 1,000. The whole district is feverish. The registration shows a fever-rate of 25·08 per 1,000, out of a total death-rate of 30 per 1,000.

Edwardesabad is comparatively a new town of 4,906 inhabitants, in Bannu. This town has been supplied with water from the Kurrain river and wells. The river water flows through the town, apparently for cleansing purposes, and is afterwards used for irrigation. Well water is raised by a Persian wheel from a depth of 120 feet, and is distributed through a closed reservoir by means of 20 brass taps, six or seven of which are set apart for Hindus. Conservancy and other arrangements of the town appear to be well attended to by the municipal committee "when under immediate supervision," but, continued Mr. Egerton, the municipal secretary, "they want initiative, and are apt "to look on sanitary measures with good-natured *toleration* rather than *energy*, which degenerates "when left to themselves into *apathy;*" and, he adds, "it is men of energy as well as intelligence and integrity who are required to work sanitary reform."

31. *Reports of Deputy Sanitary Commissioners* refer to the result of their inspections of towns and large villages in a number of districts. They disclose many defects in drainage, water-supply, paving, and cleansing, but they also show that work of some kind is being done by municipal committees.

Of the town reports, that on Jullundur is interesting, as giving a fair idea of the causes of past unhealthiness of this town. Its five years' death-rate had been 47 per 1,000, and in 1882 it had fallen to 28 per 1,000, of which 10·68 was due to fevers. This town is subject to serious invasions of epidemics, the full causes of which have not been evident in the reports of past years. In the present summary of Surgeon-Major Bennett's report there is much additional information on this subject, which it may be worth the trouble to extract, as showing the probable condition of used-up Indian towns in low undrained districts. The street drains are described as "for the most part ill laid and badly kept, . . . and more or less obstructed by silt and *débris* thrown into them." But, on the other hand, "the drains of nearly half the area of the town are flushed twice a day from "two municipal wells constructed for the purpose." In many of the larger streets the surface of the roadways was cut up into ruts, and the sideways much out of repair. Comparatively few mohallas are paved, "and on the surface of the ground are numerous depressions in which the sewage coming "from the neighbouring houses is allowed to collect. In many places house-sinks were seen at the "sides of the roadways considerably under the general level, and unprovided with outlet drains." Contrivances such as these are nothing more than pits for passing sewage into the subsoil, where it is sure to be found. Within the mohallas "filth and house sweepings were seen to be collected in heaps, and private latrines were met with from which fluid filth was issuing, and percolating into the soil." Such main drains as exist lead to flooding in heavy rains. "Round about the city walls are hollows "and depressions of surface occupied by large ponds, into which the drainage of the city and the "local floods are received. In 1875 and 1878, during the monsoon rains, a great part of the country "about Jullundur became heavily flooded from excessive rainfall, as well as from the influx of flood "waters from the north, the ground became water-logged, and a fatal form of malarious fever became "epidemic."

It is satisfactory to be informed that active steps have been taken to prevent by embankments some of the flooding, and to lessen its influence by extensive relieving drainage works. It is further proposed to effect the drainage of some of the extramural ponds. Possibly the reclamations effected by such works might contribute largely towards their cost, estimated at 2,000*l.*

It is matter of great interest to watch the results of these works on the health of Jullundur. Its fever death-rate in 1882 had apparently fallen greatly below the rate of previous years.

The following are the conservancy arrangements:—"The street sweepings, together with the "solid excreta, are removed twice a day, and used by contractors as fuel for their brick-kilns. The "zamindars are in the habit of collecting filth and house refuse in the courtyards of their houses, "and, removing it from time to time to fields, use it as a manure." This last practice ought to be put a stop to, and the whole conservancy carried out by the municipal authorities, who should also dispose of the manure.

Water is obtained from 522 wells inside and 370 outside the town, and the state of these town well waters brings us information on the state of the subsoil.

All the town samples examined showed sewage pollution. Even in the case of a new well sunk by the municipality for flushing, the water yielded sewage salts in great abundance. The reporter states that he had examined this well while in the process of construction, and found that "the soil "and subsoil to a depth of 20 feet was chiefly composed of sand and clay, with old bricks inter-"spersed, the remains of a former town, and blackened sewage deposit mixed with the soil, the whole "giving off a heavy offensive odour." From this experience it follows that no well within the town area can be safe for domestic use. But with so great an excess of water at no considerable distance from the town it ought to be matter of no great difficulty to obtain filtered water, and to convey it in pipes.

The municipal well in such a case might be of use in washing out the subsoil of the town.

It may be useful as a matter of experience to state that a well close to a large cemetery north of this town yielded water containing a considerable quantity of ammonia, but no other sewage product.

The sanitary history of Jullundur and its periodical pestilences appears to be tolerably complete. It is the history of all old neglected cities everywhere, and might have been paralleled by London in the middle ages, and in all similar cases the remedies are the same. London, with its vast population, has been cured by drainage of the subsoil and houses, by rapid removal of all sewage to a distance, by closing bad wells and substituting water of better quality, by good paving and surface drainage, and by rigid attention to cleanliness; and similar remedies in the way of prevention and cure are applicable to all such towns as Jullundur. It is necessary to state this much on account of a note in

the Deputy Sanitary Commissioner's Report, in which he says that "the whole soil is utterly contaminated, but the committee is, of course, unable to counteract this work of centuries." This may be true as regards the sanitary methods in use, but if the town were properly drained and cleansed, so as to keep all sewage and foul water out of the subsoil, if good water were provided and the existing wells filled up, the foul subsoil would, in time, be rendered innocuous by the slow process of oxidation if no addition were made to its impurities by infiltration from the surface.

32. As it is just of as much importance to avoid mistakes in sanitary works as it is to execute them where required, the following account of how work may be done to the worst possible advantage may be quoted from the same report. It relates to a small town or large village, Bangha, which has the following provision for draining:—"The sewage and drainage of about half the area of the town are "carried by a large underground sewer from near the middle of the town at the end of the Sandhola "bazaar, to the western skirt, when it ends in a ditch leading to a large pond adjoining the town "on the west; it runs in the main line of drainage from east to west, and is of sufficient capacity to "allow men to enter it, while, along its course, manholes open into it at frequent intervals. In these "holes all kinds of filth, sweeping, and house refuse are thrown, which block up the channel of the "drain, and together with the contents of street gutters opening into it, convert it into an elongated "cesspool, foul smells and noxious effluvia are freely given off, and the drain, instead of serving any "useful purpose, is a positive nuisance to the people living in its neighbourhood, and especially to "those occupying the houses under the basements of which its course lies." It does not even remove heavy rainfall. We suppose this must have been an old work; if so, the best course would be to destroy it, and to level and surface-drain the town by proper gradients to an outfall. If the work is of recent construction it would be well to publish the name of its proposer, with a full detail of the reasons for its execution. No wonder that sanitary engineering is looked at in certain quarters with suspicion when such things are possible.

33. *Hoshiarpur.*—Of this town it is stated that, "the main streets are well paved and metalled, "with sufficiently capacious open drains well protected by cement at the sides. Considerable atten-"tion appears to have been paid to the cleaning of the streets; and the drains in which the sewage "was seen to be flowing freely are flushed and swept daily. The smaller streets and 'mohullas' are "for the most part paved, many of them having well convexed surfaces with drains on either side." In some narrow streets and passages repaving was required. "The drainage of about three-fourths of "the town is carried by two large open sewers, made of solid masonry, into the main outfall sewer "drain." This drain is tapped at several places for irrigation purposes. The whole sewage of this and other outlets might be possibly similarly disposed of.

Water is obtained from 175 wells inside municipal limits, and 34 wells outside.

It is instructive to compare the analysis of samples of each made by the Deputy Sanitary Commissioner, who says that "of 10 samples obtained from the town wells, four showed the presence of chlorides, sulphates, and nitrates in considerable quantity." Seven samples obtained from wells outside were comparatively free from these salts, "and the water in all respects appeared to be pure and wholesome." To show how wells may in time become in reality the deposit drains of town sewage, it may be stated that the worst of them was a well 150 years old.

Hoshiarpur has evidently been much improved of late. It contains 18,263 inhabitants. Its death-rate in 1882 was 26 per 1,000 against the preceding five years' average rate, which was 41 per 1,000. With one single exception its fever death-rate, 7·46 per 1,000, was by much the lowest of 49 municipal towns.

Rawal Pindi district.—We have had more than once to refer to the neglected state of towns and villages in this district, and the present Report shows that the same neglect of cleansing and sanitary precautions was still met with in 1882.

34. The inspections made by civil surgeons in municipal towns revealed a similar condition of matters; it is therefore unnecessary to add to the illustrative cases given above. All reports were sent to the Sanitary Commissioner, together with the recommendations of the inspecting officer, and steps were taken by him to bring these under the notice of municipal committees.

The practical result of the year's inspecting work was to show that considerable sanitary improvements were in progress in certain towns and districts, that in others less had been done, but that in all there is plenty of simple elementary improvement necessary.

35. We cannot conclude these remarks without stating that, as we have not unfrequently felt compelled to notice the extent to which theories about epidemic diseases had apparently interfered with real sanitary work, so in the present instance we are bound to state that where these speculative views have been discarded, medical officers, so far as can be judged of from the abstracts given of their reports, have shown themselves quite competent to grasp local sanitary problems in a very practical manner, and if their advice is followed by the local authorities, future progress in diminishing the liability of the people to outbursts of epidemic diseases may be confidently expected.

In our remarks on the Report for 1880 we called attention to a singularly interesting sanitary dialogue drawn up by Mr. Bellew, and we are glad to find that "the dialogue has not only been "translated into the vernacular, under the orders of the Punjab Government, in the office of the "Director of Public Instruction, but that it has also attracted the attention of the local vernacular "newspapers and others. The editor of the 'Takmil-il-Hikmat,' a paper which is widely circulated "all over the country, has made a translation of it in his journal. The Sanitary Commissioner of "the Southern Deccan, Belgaum, has applied for a copy, and I have received an application from

" one Ayn Singh, Inspector of Police, Lahore central office, to be allowed to translate the same into " Punjabi. Fifty thousand copies of the dialogue have been printed off, and will now be supplied to " all the districts of the province at one anna per copy."

36. The Punjab appears to be on the road towards developing an active, efficient, and practical sanitary administration. In this respect it is setting an admirable example to other provinces. The one thing required at present is to bring Government influence to bear on those officials who ought to do the local sanitary work, especially in the villages, so that the inspections now being carried out on so large a scale may bear fruit.

In our "Suggestions for the Sanitary Improvement of Indian Stations" (1882) we have laid down the principles which are more or less applicable to all such cases as those described in this Report, and we cannot conclude without expressing our thanks to Mr. Bellew for the large amount of useful and interesting information which it contains.

18th January 1884.

No. 6.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for the North-West Provinces and Oudh for 1882.

1. Mr. Planck's Report for the present year commences with a terse and interesting account of the year's meteorology, drawn up by Mr. Hill, the reporter, in compliance with a request from this Commission, that, under the special epidemic conditions prevalent in the North-West Provinces and Oudh, it was necessary that statistics of disease should be accompanied by the statistical elements of climate. Our object was not the one answered by this digest, which, however, we shall refer to further on. Every year's experience of Indian epidemics has shown that a certain relation exists between the elements of climate and the epidemic mortality. It is necessary to ascertain what this relation is, and there is no other way of arriving at it except by placing side by side the statistical facts under each head. In cities and large towns there are at present, or there ought to be, daily meteorological records and daily records of deaths from the chief epidemic diseases, and all that is required is to tabulate the two records side by side on suitable forms, one for cholera, one for small-pox, and one for fever. The more important elements of climate are daily rainfall, daily maxima and minima of temperature, daily ranges and daily moisture, winds, and their direction and force. But for districts, monthly epidemic deaths under the same headings, ranged alongside the average monthly climatic elements referred to, could be made to answer our object, especially if in one or two larger towns, where all the facts are attainable, daily records were published. The subject is one of great importance, especially in irrigated and flooded districts, because it includes among its results the whole question of local drainage. Besides this practical object the time appears to have arrived when every effort should be made to obtain a more satisfactory and a more scientific basis for our knowledge of epidemic laws than can be arrived at by merely general data.

2. The population data used in the Report are those of the census of 1881, and are as follow:—

Population North-West Provinces and Oudh.

Males	22,912,556
Females	21,195,313
Total	44,107,869

3. The registered births for 1882 and the ratios on this population were—

	Numbers.	Births per 1,000 of Population.
Males	875,616	37·34
Females	780,543	36·82
Total	1,656,159	37·54

These figures represent the results of birth registration in its fourth year of existence, and they show either that the ratio of children born is larger in India than in not unprolific England, or that more births were finally recorded by the registering machinery in use than were at first reported. Unless accuracy is ensured at every transfer of a number, there will of course be errors in the final results.

4. The district birth registration is generally high in amount, but it presents great discrepancies. At one extremity of the scale we have Dehra Dun and Kumaon with birth-rates of 22·42 and 23·68 per 1,000, and at the other Shahjehanpur and Lalitpur, whose birth-rates were respectively 47·72 and 53·03 per 1,000. No doubt part of this inaccuracy in final record may be accounted for as follows:—

The Sanitary Commissioner says: "For our record of births we depend entirely upon the report "of the village and town watchmen, and yet it is absolutely impossible that these watchmen should "have cognizance of all the births that occur." But besides this source of error, which might account for the lower rates, he says further, "without doubt they hear of a great many births, and probably record all they hear of, and this more especially in the villages," a proceeding which would account for all the excesses. The Sanitary Commissioner makes a good suggestion to meet these difficulties, which is apparently worthy of some local trial, namely, that every birth should be reported by the head of the family, who might experience a feeling of gratification in doing this duty. "At least," he says, "it would have the effect of introducing the custom of report by the only reliable person, and pave the way to its more perfect realization hereafter." Eventually, if found to answer, it might be extended to reporting of deaths also.

5. The following were the deaths in 1882, and the ratio on the population of 1881:—

	Numbers.	Deaths per 1,000 of Population.
Males	794,740	34·48
Females	690,387	32·57
Total	1,485,127	33·67

The total death-rate in 1882, without taking into account any increase in the year's population, is 2·11 per 1,000 higher than the previous five years' mean; a result which may indicate better registration as well as increase of deaths, but part of the increase appears to have been due to cholera, the death-rate from which exceeded the previous five years' average by 1·18 per 1,000.

The registered death-rates, although generally higher than usual, in Indian districts varied greatly, like the registered births. Here, again, Kumaon and Dehra Dun yielded the lowest death-rates, namely, 20·56 and 21·46 per 1,000. The highest death-rates of the year were yielded by Bareilly, 52·10 per 1,000, and Terai, 59·63 per 1,000, due mainly to fevers, which gave a death-rate of 36·15 per 1,000 for the former and 47·79 for the latter district.

6. Registration of deaths is much further advanced than registration of births, for we have the following statement by the Sanitary Commissioner that "the names of all the 1,485,127 persons who died in 1882 stand recorded in the registers."

Without accepting these results as quite accurate, it is impossible to ignore them or their consequences to practical sanitary work in these provinces, and these are that the average death-rates must be accepted as showing the sanitary condition of districts, and occasional excesses above this standard, the liability of the people to suffer from epidemic outbursts, the two classes of data constituting what Mr. Planck graphically calls the local "death penalty."

7. The death-rates of 1882 divided between town and country circles yielded the following comparative ratios:—

	Population.	Deaths.	Deaths per 1,000.
Towns, 103	2,756,493	113,219	41·32
Districts, 49	41,351,376	1,371,908	33·15
Total	44,107,869	1,485,127	33·67

The town death-rate was 4·35 per 1,000 over the preceding five years' average, but the district country death-rate was 6·95 per 1,000 above the previous five years' average. The town death-rates showed great differences in amount. The lowest rate, 18·25 per 1,000, was returned from Hardoi, with a population of 10,026, against a previous five years' average of 23·44 per 1,000. The highest rate of the year, and we must hope the highest rate of any town in existence, was 73·41 per 1,000 at Sambhal in Moradabad district. This town has a population of 21,373, and its five years' death-rate was 65·59 per 1,000. No less than 35·04 per 1,000 of the enormous rate of 1882 was returned as due to fevers. The cholera rate was only ·33 per 1,000, so that for every death from cholera there were 107 deaths from fever. It would appear on the simple facts of this case, that it should be dealt with at once, for surely no instance of greater need of improvement could be cited, and there are few cases in which the results would be more satisfactory if the necessary works were intelligently planned and skilfully carried out.

8. Our next abstract gives the statistical data for sanitary purposes in each of the 49 districts of these provinces on the census of 1881, and the births and deaths of 1882. We are glad to learn that

the weekly returns of mortality in the larger municipalities are now published in the "Government Gazette."

Districts.	Population 1881.	Area in Square Miles.	Births.		Deaths.		
			Total, 1882.	Ratio per 1,000, 1882.	Total, 1882.	Ratio per 1,000, 1882.	Ratio per 1,000 previous 5 Years.
Kumaon	493,641	6,000·0	11,689	23·68	10,150	20·56	21·25

Fyzabad	1,093,319	2,889·0	37,567	34·35	37,543	34·72	26·31
Gorakhpur	2,517,720	4,598·1	110,429	43·19	85,269	32·58	29·09
Basti	1,630,612	2,752·8	65,553	40·20	48,595	29·80	29·04
Azamgarh	1,604,654	2,147·4	46,365	29·20	52,282	32·58	24·38
Ghazipur	1,014,099	1,473·0	28,538	28·14	33,179	32·72	34·33
Ballia	924,763	1,124·4	24,656	26·65	25,455	27·53	25·08
Benares	992,684	998·0	37,220	34·98	37,094	41·97	24·55
Mirzapur	1,136,796	5,223·3	37,865	33·31	41,033	36·10	25·16
Jalaun	418,142	1,469·4	17,069	40·82	12,845	30·72	31·87
Jhansi	383,227	1,566·8	15,453	46·37	12,859	38·56	33·98
Lalitpur	249,088	1,947·4	13,210	53·03	8,440	33·88	31·25
Total for the Province	44,197,869	106,103·9	1,656,159	37·34	1,485,127	33·67	31·56

This abstract table shows the present condition of registration in every district of these provinces, and it is evident, from the facts, that great progress has been made in this fundamental part of public health work, although the striking differences in the registered ratios appear to shew that local improvements in the machinery are required. But, making any reasonable allowance for inaccuracies, it is impossible not to be struck by varieties in death-rates which the table presents, and there is every reason to accept them as indexes of the district sanitary conditions. The last two columns appear to show that the death-rates of 1882 were above the average in many cases, while the total excess of deaths in 1882 over the rates of the preceding five years was 2·11 per 1,000. The birth-rate was also above the averages for two preceding years, which were 28·69 and 32·55 per 1,000.

9. Following our usual order, we shall next give an analysis of the death causes in 1882, and the lessons which the facts appear to teach.

Diseases.	Total Registered Deaths.	Deaths per 1,000 of Population.
Cholera	89,872	2·03
Small-pox	26,628	0·60
Fevers	1,098,414	24·90
Bowel complaints	93,661	2·12
Injuries	21,133	0·49
All other causes	155,919	3·53
Total	1,485,127	33·67

In 1882 these provinces were visited by a severe epidemic of cholera, and yet a reference to this abstract shows that, of assigned death causes, injuries and small-pox alone yielded lower death-rates. The bowel complaint mortality exceeded the cholera mortality by 4,289 deaths, while the fever mortality was above twelve times that from cholera. We have often insisted on the necessity of facts of this class being taken into account as affording a clue to sanitary work. As will be seen in the present case, war has to be waged not so much with the localizing causes of cholera as with the causes of fever, which, for all practical purposes, include the removable causes of cholera, although the local causes of cholera do not necessarily include all the causes of fever.

10. We shall next give a brief sketch of the epidemic history of 1882, beginning with cholera. The following abstract shows the annual prevalence of cholera in the North-West Provinces from 1865 to 1876, and then in the conjoined North-West Provinces and Oudh for five years, 1877 to 1882:—

Years.	Cholera Deaths per 1,000 of Population.	Years.	Cholera Deaths per 1,000 of Population.
1865	2·53	1874	·20
1866	·32	1875	1·33
1867	1·95	1876	·95
1868	·64	1877	·74
1869	3·06	1878	·52
1870	·44	1879	·84
1871	·11	1880	·67
1872	1·64	1881	·58
1873	·49	1882	2·02

These figures, up to 1869, show epidemic augmentation every second year until 1869, then a triennial augmentation up to 1875, since which year the annual cholera death-rate has been under one per 1,000 until 1882, when it rose to 2·02 per 1,000. The death-rates from this epidemic in town and country circles were as follow:—

Localities.	Population, 1881.	Deaths from Cholera.	
		Number.	Ratio per 1,000 of Population.
103 towns	2,756,493	4,801	1·74
49 districts	41,351,376	84,471	2·04
Total	44,107,869	89,272	2·02

11. Cholera was by no means universally diffused either among towns or districts. The town mortality was all yielded by 56 towns, of which 15 had seven deaths and under, several of them only one death. It is true that all the 49 districts, except two, returned deaths, but these districts contain 1,143 registration circles, of which 668 were attacked, and, following the usual law of diffusion, cholera deaths were returned from 10,338 villages, out of a total of 105,321 in the provinces.

12. When the facts are examined more in detail, they appear to show that the cholera of 1882 owed much of its severity to local epidemic intensity (using this expression to describe a simple fact and not a theory). For example, the city of Agra, with a population of 119,079, had only three cholera deaths, or a ratio of ·02 per 1,000. Mainpuri, with a population of 20,236, yielded one cholera death, or a rate of ·05 per 1,000. Muttra had a single cholera death from among 44,775 inhabitants, or ·02 per 1,000. Aligarh, out of 61,730 people, lost 16 by cholera, or 0·26 per 1,000. This group of towns, and a number of others with low death-rates, all lie south of the Ganges.

We shall take another group. Bareilly has a population of 103,160 people, of whom 235, or 2·28 per 1,000, died of cholera. Aoula, in the same district, with 13,108 inhabitants, lost 175, or 13·44 per 1,000. Etawah, with 34,721 people, yielded 213 cholera deaths, or 6·14 per 1,000. Lucknow, with a population of 239,773, had 663 cholera deaths, or 2·76 per 1,000. Rudauli lost 188 people, or 16·49 per 1,000, out of a population of 11,394, and Jais, out of 11,044 inhabitants, yielded 143 cholera deaths, or a ratio of 12·95 per 1,000. These towns all lie among the rivers to the north of the Ganges.

13. The city of Allahabad, between the Ganges and Jumna at their point of union, deserves separate mention, because it was the seat of the great pilgrimage in January 1882, which was attended by three millions of people. The town was crowded by pilgrims, and cholera broke out among them, not only on the bathing site, but in Allahabad itself; and numerous cholera cases were taken into the city for treatment. The population of Allahabad is 87,664, and there were 106 deaths from cholera in the course of the year, or 1·21 per 1,000. Of the 56 attacked towns, 33 had cholera death-rates exceeding that of this pilgrimage town. At the other extremity of the North-West Provinces are the districts about the site of Hurdwar fair, which was held immediately after the Allahabad mela. There was an imported choleraic case at the fair, but no cholera, and the adjacent circles escaped the disease.

14. Taken according to districts, there were several such in Meerut, in which only two or three cases were registered. The lowest registered rates were in Bijnor and Etah, namely, ·01 per 1,000. The highest district rate was returned from Pilibhit, namely, 12·66 per 1,000. Sitapur had a rate of 9·57 per 1,000, and Allahabad, of 1·02 per 1,000. The cholera epidemic of 1882 was most severe in districts north of the Ganges, and in the countries traversed by great rivers, especially near their points of junction. It is worthy of remark that the great irrigated districts lying between the Ganges and Jumna nearly escaped the disease, or at least comparatively.

15. The following were the monthly registered cholera deaths in 1882 :—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
January	1,408	July	12,084
February	1,424	August	16,443
March	2,410	September	13,682
April	10,525	October	13,642
May	5,375	November	2,100
June	8,983	December	226

In tracing the history of an epidemic, especially in its relation to pilgrimages, dates are of the highest importance, but there are no dates available in the present case, except those of monthly prevalence. When the pilgrims departed from Allahabad they were under cholera influence, and many died on the lines of railroad, as well as on the ordinary country roads, but the deaths, so far as could be ascertained at the time, took place solely among pilgrims. The present Report contains no further statistical information on the subject. It is merely stated generally that of a total of 1,403 deaths from cholera recorded throughout the province in that month (January), 1,272 were registered amongst the people living within a radius of 100 miles from that city (Allahabad), and that in February, of 1,424 cholera deaths, 1,110 were registered among the same people. But this fact may have arisen simply because of the relative position of Allahabad in the south-eastern epidemic region of these provinces, where cholera epidemics usually begin in connexion with cholera in Bengal. We learn from the tables that in January there were 335 deaths from cholera in the seven districts of Benares division. But in the same month cholera had shown its presence in most of the districts and in all the divisions of these provinces, except Jhansi, and that in the subsequent months the epidemic followed its usual course of progress, like a rising wave, from the south-east to the north-west, where it attained its maximum mortality after this had declined in the south-east districts.

16. The general epidemic history of 1882 is well summarized by the Sanitary Commissioner in the following passages of his report :—"Noticing particularly the ratios of 1882, it may be observed "that this cholera prevalence occurred amongst the people of the eastern districts, neighbouring " Bengal, and of Oudh, and of Rohilcund, sparing in great measure the people of the Doab, of the " five northern districts Kumaon, Gharwal, Tarai, Bijnor, and Moradabad, and of the three " southern districts, Jalaun, Jhansi, and Lalitpur. Indeed, it may be stated, with a great " approach to correctness, that cholera disease in the epidemic form in 1882 affected only the " population living between the Ganges and the Himalayas, and there, indeed, only in selected " centres of population. . . . . The serious and unexpected mortality from this cause " was that which occurred in the north-western districts, Lucknow, Bara Banki, Sitapur, Kheri, " Shahjehanpur, Budaon, Bareilly, and Pilibhit. These districts form a continuous country north " of the Ganges river, and their mean ratio of mortality from cholera in 1882 is 5·56 per 1,000. " The epidemic in the western districts commenced at the very time the epidemic prevalence ceased " in the eastern districts. This is in accordance with the usual experience, which intimates plainly " that epidemic cholera disease may be expected to prevail early in the year in the eastern districts, " and late in the year in the western districts of the province.

"So invariable has the rule appeared, that one of two things seems certain, either the cause of the " epidemic prevalence travels from east to west, or the local conditions upon which it depends for " vitality are developed at a later period of the year, in the western districts."

We need scarcely point out that these problems are the very ones for which for practical purposes it is most desirable to find a solution, and it was for this purpose, among others, that we were desirous of obtaining meteorological data. Not a general monthly discussion of climates, but statistical data for districts. To show the importance of this requirement, we shall give the monthly prevalence of cholera in Benares division, with a population of 9,367,643 in the south-east of the provinces, and in Rohilcund of 4,602,846 in the north-west.

Months.	Cholera Deaths.	
	Benares.	Rohilcund.
January	338	2
February	175	4
March	693	5
April	7,241	8
May	3,293	7
June	4,315	48
July	5,366	259
August	9,479	3,065
September	993	6,965
October	654	7,325
November	104	403
December	37	24

It will be seen from these figures that the epidemic wave reached Rohilcund in June; that in July it was falling in Benares division and rising in Rohilcund; that in August, September, and October the epidemic transfer was completed between the districts, and that in the concluding weeks of the year subsidence at both ends of the line took place. Now it is most desirable that we should have more light than we possess on the causes of this very remarkable phenomenon. It is very probable that this may come from meteorological facts, which ought to show the succession of climatic elements in each district to place alongside the epidemic succession in each. With such facts before him, the Sanitary Commissioner would be better able to arrive at a conclusion on the important question how far these elements of climate act independently, or through the agency of local causes and conditions.

This information is too imperfectly given in the general discussion on climate in the present Report to be of use, but it can easily be made sufficient from existing records.

17. On the question of localizing causes of cholera, there is a fact mentioned of grave importance, although it ought not to be an unexpected one. The Sanitary Commissioner gives a list of 616 localities, together with the deaths from cholera registered in each, and referring to this list he says, "By comparison of this list with the list of previous years, it may be learnt that some centres "of population are becoming noted as places of cholera epidemic prevalence. But they are not as "yet numerous. As years pass, I have little doubt they will increase in number, to the ultimate "determination of the places in each district where sanitary improvement is most desirable." Ought not this point to have been put otherwise? Does not the occurrence of a single death from cholera indicate a local danger, to be immediately dealt with? and ought not centres of population becoming more liable to cholera to be taken as showing the results of previous sanitary neglect? The distinction is an important one, and contains a principle everywhere applicable, namely, that where cholera has been allowed for once to locate itself, it is liable to return at next epidemic. In England, the first case in a previous cholera locality has been known to occur not only in the same house and in the same room, but in the same bed. In the words of the Sanitary Commissioner applied to the amount of cholera in particular places, "This proof of special prevalence in certain localities, which I may "say has always characterized cholera outbreak in this province, points unmistakeably to some "peculiar condition of locality as favouring this unexpected mortality. The generally accepted "belief is, that a neglected sanitary management is answerable for that condition. And without "doubt, wherever cholera disease appears in epidemic force, a great responsibility rests upon the "local authorities in regard to the necessity for improvement in the centres selected for especial "preference by this terrible disease."

This is true, but the responsibility begins before the epidemic comes, and the victims it selects in all localities are simply the penalties levied on previous neglects of duty. This is the sum of the whole matter.

18. *Small-pox.*—Deaths from this disease in the rural districts of these provinces were 21,296 in number, equal to a death-rate of ·51 per 1,000 of the rural population. In the towns there were 5,332 deaths, equal to a ratio of 1·33 per 1,000. In town and country combined, the small-pox deaths numbered 26,628, giving a death-rate ·60 per 1,000 for the whole population, against a previous five years' death-rate of 1·39 per 1,000.

The past death-rates for the 49 districts in the North-West Provinces and Oudh have been as follows:—

Years.	Small-pox Deaths per 1,000 of Population.	Years.	Small-pox Deaths per 1,000 of Population.
1870	·8	1877	·8
1871	1·2	1878	3·9
1872	1·1	1879	1·7
1873	2·8	1880	·1
1874	2·5	1881	·8
1875	0·7	1882	·6
1876	0·9		

The year 1878 was the year of scarcity of food, and yielded a true epidemic death-rate from small-pox, as was the case in other districts of India.

The distribution of small-pox mortality among the 49 districts presents some curious anomalies during the 13 years in this table. Some of the districts have yielded small-pox deaths in every year. In others a year or two now and then have been exempt. In others, again, the earlier years or the later years alone have suffered. In no one year have all the 49 districts registered deaths from this disease. Generally, two, or perhaps three, districts have escaped, but during the last three years there has been a marked reduction in the area covered by small-pox. Thus, in 1880 no deaths were registered in 31 districts, in 1881 none were registered in 23 districts, and during the last year of the series 22 districts alone yielded the small-pox mortality of 1882. This fact only implies that in many districts the mortality was too small to yield ratios, for, as a matter of record, every district yielded small-pox deaths in 1882 except Dehra Dun. Out of 1,143 circles of registration, 637 were affected, but the entire year's mortality was yielded by 8,403 villages out of a total of 105,421.

19. The monthly mortality from small-pox was as follows :—

Months.	Deaths from Small-pox.	Months.	Deaths from Small-pox.
January	514	July	3,238
February	617	August	1,422
March	1,217	September	562
April	2,218	October	491
May	4,665	November	1,294
June	4,963	December	5,271

This table bears marks of two epidemic outbreaks, one in the hot season and the other at the end of the year, but this latter augmentation took place chiefly in Lucknow district. The most severely affected district was Lalitpur, which yielded a small-pox death-rate of 5·94 per 1,000. In this area small-pox deaths were registered during every month of the year, and 22 registration circles out of 24 yielded deaths.

The same law held in this and other severely affected districts, as we have shown often to be the law of cholera. Lalitpur contains 670 population groups, of which the large proportion of 660 suffered from what was a distinct local epidemic, showing the necessity for increased vigilance in sanitary work, including vaccination.

20. *Vaccination.*—The following abstract, showing the numbers vaccinated for a series of years, is of importance when considered in relation to a statement of the Sanitary Commissioner about the figures :—

Years.	Successful Primary Vaccinations.	Years.	Successful Primary Vaccinations.
1870	199,674	1877	625,064
1871	286,997	1878	622,458
1872	337,593	1879	524,735
1873	369,916	1880	640,224
1874	375,244	1881	684,026
1875	430,906	1882	598,906
1876	532,861		

Of late years, as will be seen, there has been a great increase of vaccination operations pronounced to be "successful," but a large falling off in 1882; and the following is the explanation given :—"As a "matter of fact, the apparent decrease of primary operations in 1882 has not been due to any serious "decrease of efficient vaccination in that year, but to the elimination from the record of cases of "pretended primary vaccination which had vitiated the total results of previous years, raising them "to a figure of progress to which they have no just claim." The error appears to have been mainly incurred in Oudh, Rohilcund, and Kumaon, where the vaccinations admitted fell short by 93,195 of the preceding year's number.

Where the successful vaccinations are the results calculated on percentages examined, errors of this kind are very likely to happen; but we may place the vaccinations, as a whole, alongside the yearly mortality from small-pox given in a preceding table, and by doing this we obtain what appears to be satisfactory evidence of lowered small-pox mortality.

If, however, the actual births be compared with the successful vaccinations of the last four years, we shall at once see that great extension of vaccination work in these provinces is necessary, but, unfortunately, the deaths among children are not available to complete the data, which are as follow :—

Years.	Births.	Successful Vaccinations.
1879	1,225,832	524,735
1880	1,390,870	640,224
1881	1,779,473	684,026
1882	1,656,159	598,906
Total	6,052,334	2,447,891

It is probable that the actually protective vaccinations do not much exceed one-third of the births, but the vaccinations include all ages, and not merely infants.

The successful vaccinations according to age were—

Under one year	258,200
Over one and under six years	288,784
Total of all ages	598,906

which last is the corrected number given in the preceding table. The general result is, that in 1882 about 15½ per cent. of the children born may possibly have been vaccinated, but allowance must be made for those born in 1881. Statistically, however, the vaccinations in infants amounted to 15½ per cent. of the births, a very small ratio when dependence is placed on this protective power of vaccination, and showing how large an extension the work requires.

21. The vaccination staff under the Sanitary Commissioner for 1882 was as follows:—

Superintendents of circles	5
Deputy superintendents of circles	7
Native superintendents	50
First class vaccinators	273
Second „ „	345
Servants, &c.	63
Total staff	743

Successful vaccinations and re-vaccinations amounted together to 693,792. The total cost was Rs. 117,686 14 7, and the average cost of each successful operation was As. 3·1. The facts as a whole show clearly the present condition of the work, and where improvement is required.

22. *Fevers.*—We shall begin our notice of this class of diseases by referring, in the words of the Sanitary Commissioner, to the unsatisfactory nature of disease definitions, to which we have directed attention year after year.

Mr. Planck says, "As a general rule, almost all deaths from diseases of the general system other "than fever, almost all the deaths from diseases of the internal organs, are returned as deaths from "fever, because a feverish condition is a symptom of such diseases. And this extraordinary and most "vexatious circumstance is due in great measure to the careless and uneducated character of reporting "agents, the country watchmen."

The complaint is the same all over India, and there is no use concealing the fact that Indian fever registration is quite unreliable. We have formerly suggested that possibly some improvement might be introduced in this important statistical division if an instruction were issued to the reporters to cease recording deaths as from fever where heat of skin was the only diagnostic mark relied on, and to substitute for it paroxysmal character. But if this mark were adopted, it would have to be adopted generally, or errors of another kind would be introduced.

23. As already stated, the deaths assigned to "fevers" in the registration returns of these Provinces amounted to no fewer than 1,098,414 during the year 1882. The fever death-rate of the year was for males 25·58 per 1,000, and for females 24·16 per 1,000. The average rate for both sexes was 24·90 per 1,000, which was 1·05 per 1,000 above the preceding five years' average.

The fever death-rate in country districts was 24·86 per 1,000, and in the towns 25·57 per 1,000.

A sufficient indication of the extent of registration error is afforded by the fact that nearly 74 per cent. of the total mortality in 1882 is assigned to this one cause. Every district returned fever deaths in 1882, and 1,116 circles of registration out of 1,143 made similar returns.

All towns making returns of deaths and nearly all villages, 105,421 in number, reported fever deaths.

The monthly numbers were as follow:—

Months.	Deaths from Fever.	Months.	Deaths from Fever.
January	93,302	July	81,170
February	73,796	August	103,139
March	75,183	September	144,663
April	76,183	October	114,788
May	87,832	November	102,533
June	79,423	December	96,403

This table shows a preponderance of fever mortality during the fever months, but not to such an extent as might have been anticipated had the diagnosis been more accurate.

24. Fever mortality was lowest in Jhansi division, in which division Lalitpur district registered a fever death-rate of 7·27 per 1,000 against a previous five years' average of 11·15 per 1,000. In other districs most of the death-rates were between 20 and 30 per 1,000, and the highest rate of the year was in the Tarai, namely, 47·79 per 1,000, against a previous five years' rate of 34·03 per 1,000. Town fever death-rates varied considerably; the lowest of the year, 7·49 per 1,000, was in Lalitpur town, and the highest, 70·94 per 1,000, took place in Ajudhia. In a number of towns the death-rates were 4 and 5 per cent.; but, generally, the town death-rates were lower than those of districts, due, probably, to less inaccurate registration.

The great fever mortality in the Tarai is apparently due to local and climatic peculiarities, but the Sanitary Commissioner states, that it "occurs chiefly amongst persons who are unacclimatized settlers "in the district." Indeed, he says, "I think only the Tarus or aboriginal inhabitants of this district "escape from attack of fever disease, which prevails at one time or other of the year against every "foreigner."

25. The relation of canal irrigation works to increase of fever death-rates is again referred to in the present report, although it cannot be said that any fresh light has been obtained on the subject. Only the fact is, year by year, more firmly established that such a relation exists. A remarkable instance is cited in Fatehpur district, in which, under extending canal irrigation works, the fever death-rates during ten successive years ending 1882 have been in the following annual ratios per 1,000 :—12·2, 9·7, 10·5, 13·0, 10·6, 15·5, 37·6, 32·0, 28·2, 31·56. The ratio of 37·6 per 1,000 marks the irrigation period. "Meerut, Saharanpur, Cawnpore, and Mazaffarnagar, all districts of excessive "canal irrigation, witness to the continued action in that year (1882) of this cause of excessive "deaths." In these districts the fever death-rates were 30·96, 29·09, 29·0, and 28·32 per 1,000 respectively.

In the irrigated districts, taken as a whole, the fever-death-rates were all high in 1882, and, to show the past fever history of these districts, we may quote the following table from the present year's report :—

Districts under Canal Irrigation.	Fever Deaths per 1,000 of Population.				
	1878.	1879.	1880.	1881.	1882.
Saharanpur	21·7	42·4	31·9	27·1	29·0
Muzaffarnagar	26·7	58·7	42·5	29·2	28·3
Meerut	25·4	81·9	42·2	33·5	30·9
Bulandshahr	21·6	118·7	28·9	29·1	25·6
Aligarh	21·1	118·5	23·8	23·4	20·6
Etah	23·7	57·8	23·3	25·4	27·0
Farukhabad	29·8	42·7	29·3	27·2	27·6
Mainpuri	27·4	63·4	29·7	26·4	27·5
Etawah	24·7	45·8	31·0	26·6	24·5
Cawnpore	20·6	46·3	29·0	26·2	29·0
Muttra	59·0	63·9	22·2	22·4	22·5
Agra	37·3	52·3	21·6	22·4	24·3
Mean	29·1	67·9	28·0	26·5	26·8

We have already seen that the fever mortality for the Provinces was 24·90 per 1,000 in 1882, with which may be compared the rate for these districts, 26·3 per 1,000 in the same year, but it must be borne in mind that the total rate of 1882 includes the higher rates of these irrigated districts. We thus arrive at the conclusion that, if the errors in diagnosis are similar all over the Provinces, the fever death-rate is everywhere very high, and that this high rate is exceeded in the irrigated districts by 1·4 per 1,000 at least.

26. The meteorological data given in the present report do not enable us to arrive either at the localization or distribution of rain, so that it is impossible to separate the influence of rainfall from that of irrigation.

What the probable influence of this latter element may be can be judged of by the following account of irrigation practice in these districts :—"There cannot be a doubt," says the Sanitary Commissioner, "that extensive irrigation operations do tend to increase fever prevalence and "mortality, and that such result must be accepted as one of its unavoidable attendants. The medical "history of Northern Italy witnesses to the truth of this, and there, I believe, the actual irrigation of "land neighbouring the habited site is forbidden. No such rule is enforced in this province, and "nothing is more common than the persistent irrigation of land touching the walls of the habitations. "As a result, many habitations of canal irrigated districts may be found with dampness permeating "the walls up to the tiles or thatch which form the roof. Of all the causes favouring the attack of "fever disease perhaps none is so potent as residence in a damp house."

This general statement of the case may be accepted as correct, but we cannot admit that the excessive fever rates of these irrigated districts are amongst the "unavoidable attendants" of irrigation. In most of the warmer districts of Southern Europe, where there is deep soil under wet cultivation, there is fever, as there is fever in districts of an opposite character. The only difference as regards India lies in the condition of the people, and in their far higher fever death-rates even where there are no irrigation works, which death-rates are subject to sudden and great augmentation everywhere, but especially in irrigated districts by abnormal rainfall. When there is superadded scarcity of food, for the prevention of which irrigation works have been carried out, these fever death-rates may assume the character of a pestilence. The point for consideration, therefore, is, whether the occasional loss of life from scarcity would be less without irrigation than it is known to be at present under irrigation and abnormal rainfall in a series of fairly plentiful years. The account of dwellings given in the preceding extract furnishes the reply, for no population living under such conditions can escape great loss of life year after year from fever. And the sanitary problem is simply how to obtain the unquestionable benefits of irrigation to the food supply of the people without a great annual destruction of life from wet subsoil and damp habitations. The answer must be that, beyond the possibility of doubt, excess of water added to the soil of these provinces, especially in cases where there is an impervious subsoil which retains it, and more especially in saline soils where putrid decomposition is likely to take place in organic matters in these wet saline soils, is the most potent known agent of fever causation. The remedy is, of course, generally that drainage of subsoil should accompany irrigation, and that some method should be adopted to limit or apportion the amount of water applied to the land. There are, no doubt, also local drainage problems requiring

separate study; but, taking everything into consideration, we feel quite warranted in stating that high fever death-rates are not "unavoidable attendants" on proper irrigation, drainage, and agriculture, and this is true even if it be admitted that it would be practically impossible to extirpate fever and its causes in India or elsewhere.

27. These remedies, however, are quite apart from sanitary measures applicable at present to every village and town; the chief of these are cleansing and keeping clean, protecting water sources, filling up water holes, and local drainage cuts to free the subsoil under houses from excess of water. Raising the floors of the houses above the ground level should also be done. All this is well known; but if fever mortality is to be diminished in these Provinces, it can only be accomplished by translating the knowledge we possess of local fever causes into practical action for their removal.

28. *Bowel Complaints.*—The following was the monthly mortality from diseases classed under this head in 1882 :—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	6,124	July	8,699
February	5,092	August	19,111
March	5,085	September	11,695
April	5,772	October	10,636
May	6,673	November	8,267
June	6,446	December	7,062

Of these deaths, 12,510, equal to a death-rate of 4·54 per 1,000, took place in the towns, and 81,151 in country districts, giving for the latter a death-rate of 1·96 per 1,000. The total bowel complaint death-rate for the Provinces was 2·12 per 1,000, against a previous five years' average of 2·20 per 1,000. The number of population groups furnishing the deaths is not given in the returns, but these diseases prevailed in all the registration districts, and in 1,068 registration circles out of 1,143 in the Provinces.

The Sanitary Commissioner thinks that deaths classed under this head are chiefly from dysentery, and he points to the fact of the greater mortality from them in the autumn months appearing to indicate a malarious origin.

If this be the case the remedial measures against them would fall under the same category as those against fever. There must be local causes of some kind for the much greater fatality from bowel diseases in certain districts than in others. Why, for example, should Hamirpur yield a rate of 7·93 per 1,000 per annum raised in 1882 to 10·38 per 1,000, or Garwhál have a bowel complaint death of 9·64 per 1,000 in 1882, and a previous five years' rate of 6·99 per 1,000, while there are 17 districts in which the death-rate is under 1 per 1,000? most of them less than half this amount. It is by investigating problems of this kind that light is most probably to be obtained on the causation of disease.

29. *Injuries and Accidents.*—Under these heads were registered 21,133 deaths in 1882 = ·49 per 1,000 of the population. The chief causes were—

Suicides, Males	615
" Females	1,645
Wounds and accidents	12,358
Snake-bite and wild beasts	6,515
Total	21,133

The remark made on the last of these heads by the Sanitary Commissioner is "the registration of "the last five years appears to witness to a progressive increase of deaths from snake-bite and attack "of wild beasts." What appears to be required in this matter is more outlay in the way of reward, and greater activity in this branch of the public health service.

30. *All other causes.*—No fewer than 155,919 deaths, or a death-rate of 3·53 per 1,000 of the entire population, were returned under this head. The town registration showed 7·15 per 1,000 in circles where registration ought to be so far advanced as to reduce materially the number of deaths, of the causes of which we have at present no knowledge.

31. We shall conclude our remarks on the disease history of 1882 by introducing the following statistical data for 24 cantonments in the North-West Provinces and Oudh :—

Population, 1881	193,049
Deaths, all causes, 1882	4,680
Or 24·24 per 1,000.	
Of these,—	
Deaths from cholera	53
Small-pox	11
Fevers	3,162
Bowel complaints	329
Injuries	74
All other causes	1,051

It cannot be said that these cantonment populations are healthy while nearly three-fourths of the entire mortality were due to fevers in 1882.

32. *Sanitary Works (Civil).*—The following summary of the year's sanitary work is given by the Sanitary Commissioner:—"Works of sanitary improvement continued to be effected throughout the "year in all parts of the province. I select those most worthy of record, excluding a great number "of minor improvements of this character which are locally important, without doubt, and attended "with considerable benefit to the populations concerned, but do not require separate record. Indeed, "it may be truthfully said that sanitary improvement characterizes the management of every important "centre of population, so general is the desire to improve their appearance and condition as places "of residence."

We accept this statement as satisfactory so far as it goes, provided the actual sanitary condition of the people, as shown by the statistics, is not overlooked, for we find that while the total death-rate for five years averaged 26·20 per 1,000 per annum for the rural population, this had risen in 1882 to 33·15 per 1,000. For the towns, however, there is statistical evidence of improvement in the fact that the death-rate in 1882, which was 41·32 per 1,000, very high, no doubt, showed a considerable reduction below the preceding five years' average rate, which was 45·67 per 1,000.

The statement of sanitary works, referred to by the Sanitary Commissioner, includes 83 cities or districts, and are of the usual simple proceedings, such as surface drainage, well cleansing, water-supply, filling up hollows, provision of latrines, paving, tree-planting, improved conservancy, and the like. The most important works have been the completion of the Almora water scheme, by which water is brought to the town from its source in an iron pipe to a covered reservoir, whence it has been distributed to the people. In Saharanpur town "a large number of filthy lanes in the most "densely crowded parts of the town were paved and drained. Most of the cesspools were done away "with." Provision was being made for flushing out the surface drains by water taken from the Jumna Canal. This essential addition to all town surface drainage works was completed at Roorkee, and successfully worked with beneficial results.

At Cawnpore a pipe drain was being laid for carrying canal water to flush out the main drainage channel.

The survey of Gorakpur town had been completed, and the main drainage lines determined.

The surface drainage of Lucknow was being extended and other improvements carried out, but this large city has still to be provided with proper drinking water.

The chief work at Benares appears to have been filling up holes with town sweepings and rubbish. The Sanitary Commissioner very properly observes that "the resulting surface will not be a safe residence for men," and he advises the only safe treatment of such cases by tree-planting, and also we would add by cultivation or the formation of garden ground.

33. Whatever importance may be attached to these very partial improvements, it cannot be questioned that the following statistical evidence of their real sanitary state amounts to a proof that local disease causes in these towns have only as yet been very partially dealt with.

Towns.	Population, 1881.	All Causes Death-rates per 1,000.		Fever Deaths per 1,000, 1882.
		1882.	Previous Five Years.	
Saharanpur	59,194	37·47	38·19	20·46
Gorakpur	55,936	30·84	36·02	21·93
Cawnpore	120,161	53·63	47·17	36·70
Lucknow	239,773	54·02	45·68	27·10
Benares	193,925	52·23	31·85	34·20

34. *General remarks.*—The first point of importance requiring notice under this head is the account given of the Allahabad mela of 1883, in contrast with the previous year's mela of 1882. On this latter occasion some three millions of pilgrims were crowded on the triangular area between the Ganges and Jumna without due sanitary preparation, and cholera broke out among them. At the next mela in 1883, there were some 300,000 persons present. "Comprehensive and efficient measures were enforced," says the Sanitary Commissioner, "in aid of the general and sanitary welfare of the "assembled people under the immediate orders and direction of the magistrates. . . . A "remarkable surface cleanliness was maintained everywhere in the fair site and in its neighbourhood. ". . . . All the conditions of lessened crowd, drier site, improved cleanliness, greater order, "conspired to give the fair of 1882–83 a character of comparative pleasantness from a sanitary point "of view. . . . . Certainly no disease like cholera occurred from the beginning to the end of "the mela."

At this fair we have another example of application of sanitary principles and freedom from epidemic disease. Another point ought also to be noticed as bearing on the question of healthy and unhealthy camping sites, and this is as follows:—During the great fair of 1882 with its three millions of visitors the whole site was polluted when the crowd dispersed.

In the course of the year the rise of the rivers "newly fashioned" the site; it was higher raised, and firmer than during the great mela of January 1882, and, no doubt, the subsoil was also cleansed by the year's rains.

35. The following important statement on the influence of railway communication on sanitary works is made by Mr. Planck:—"As a rule the sanitary aspect of the centres of population inspected "was satisfactory. Wherever means are provided for the realization of improvement, and local "authority exists to direct it, a very commendable advancement is apparent. So considerable, indeed, "as quite to alter for the better the appearance of places formerly characterized to my knowledge by "appearance of neglect and careless management. The advancement in aspect of respectability and "improved sanitation is most obvious in towns which have been provided with railway communication. "Almost without exception this result of better management seems to follow upon the opening out "of communication, so that I have come to look upon the railways as the greatest power in aid of "my especial work. Wherever the railways go, there inspections multiply; things unknown before, "or only suspected, come to the surface. And wherever knowledge of marked insanitary conditions "is acquirrd by frequent observation, there improvement follows. Streets are paved, excavations are "filled up, surface impurities removed, over-crowded quarters opened out." These are not the least among the important results already achieved in India by railway communication, but there is nevertheless a small and fortunately diminishing section of etiologists who would set at nought these advantages, and have us believe that railways are among the chief vehicles of epidemic cholera.

36. The Report under review contains little sanitary detail. The Commissioner appears to have been chiefly occupied in the investigation of false vaccination returns, and in overlooking the registration. Towns and villages were also visited, but the details are not given. Generally, however, he states that the recently appointed local authorities have not as yet fairly entered on their work. "The district boards do not yet perhaps quite apprehend their new position, or the opportunity it "confers of doing good." But he at the same time says that "certainly nothing of improvement "already established in the towns lately inspected has been allowed to fall back." This is so far well; but it refers only to the towns, for he says that "little, if anything, has yet been done, I think, "to better the condition of the smaller market townships, or chief villages of a group." These are the places where local produce is brought for sale. As a general rule their market-places are much neglected, the surface undrained, often broken into holes. The wells also require attention.

37. The only sanitary notes are those taken from a report of Dr. Pringle, of the first vaccination circle, who states as follows:—That the wells in cantonments generally in his circle are not properly cared for; that so plentiful is the fall of leaves into them that a thick layer of leaf mould collects at the bottom of the well, the water which rises through it having "hurtful properties likely to produce fever, dysentery, or diarrhœa."

In regard to the water-supply of Chakrata, Dr. Pringle states that the supply tanks "collect contaminated water likely to cause typhoid fever in the consumers" (troops sent there for their health), and he urges the use of iron pipes without delay.

At Landour, he states his opinion that soda-water has been made from the impure water of a tank into which sewage entered.

At Mussoori a permanent water-supply has been provided out of municipal revenues, at the cost of Rs. 30,000, "a permanent sanitary improvement without equal in any municipality in India." And he contrasts with this work and its cost the expenditure of Rs. 30,000 a year at Chakrata for the "carriage of water on mules" there.

The supply of Dehra Dun is liable to pollution by native habits along its channel, and Dr. Pringle proposes to filter it. But the only real remedy is to convey the water in closed pipes along all the course where such pollution is possible. He further advocates a very proper substitution of pumps for raising water at railway stations, instead of permitting the use of cords and lotas in all states of impurity for drawing water. He advocates the use of Bull's dredger for cleansing wells to improve the water-supply and reduce the prevalence of fever among the people. The prohibition of slaughtering animals within town sites is also advocated.

There is a leper asylum at Dehra Dun, containing 58 inmates. It is doing much good in its sphere, but may soon have to be closed unless assisted by Government. This is a matter which appears worth considering. The only other point in Dr. Pringle's report concerns the unhealthy central prison at Meerut, which it is proposed to remove to a new site, "as it is impossible to improve the existing site, because, being two low, it is water-logged beyond any possibility of efficient drainage."

This case, like many others in India, shows the need of correct topographical knowledge of soils, subsoils, means of drainage, &c. before a site is selected for building on, and the proposed remedy with its great cost might probably have been rendered unnecessary if the principle we long ago laid down had been observed, namely, that if a site does not admit of being efficiently drained it should not be adopted.

38. We have endeavoured in the preceding paragraphs to give an abstract of the disease history of the North-West Provinces and Oudh, and also of such an account as is available of the sanitary state of population and the works and measures in progress for its improvement. It cannot be said that the practical sanitary administration in these Provinces has overtaken the work of the sanitary inspector and reporter. No man has worked harder than Mr. Planck to expose the sanitary defects under which this great population lives, and, after many years of effort, he has been obliged in this the latest of them to give us such an account of the public health as to show that real fundamental progress in dealing with the causes which have decimated the people has scarcely been entered on. It is true that much surface work has been done among the comparatively small population of the towns. But what of the 105,421 villages with their 41,351,375 inhabitants? Can it be said in the face of these death statistics that anything has been done for them to save life? We can only deal with the facts as they come before us, and surely if any step could be justified by such an exposure as

they have made it is an earnest recommendation that the administrative authorities should make it a chief object to consider them, and to proceed without delay to deal effectually with the worst cases at least. We have long ago pointed out in our "Suggestions" the simple measures of cleansing and keeping clean, protection of wells and water sources, drainage, equalizing the surface, removing manure beyond the boundaries of villages, and cattle from houses and house compounds, which would do much to improve the health of village populations all over India; we have also called attention to the fact that surface and outside improvements in towns may leave untouched the real disease causes within houses and compounds.

The new municipal authorities require to be instructed in their duties, and measures adopted to ensure as far as practicable that these duties are efficiently performed. But the chief sanitary duties lie among the village populations, and some method to be determined by Government requires to be applied, whereby the village authorities may be required to do their duties in this matter. The end of the whole discussion is that the sanitary inspector and reporter has done his work, and the administrative officer has still to enter on his proper function.

In the matter of irrigation and drainage proceedings must necessarily be taken by the Government, but some method should be adopted to limit the use of irrigation water to the simple requirements of agriculture.

And above all, no time should be lost in turning the information already at hand to practical use.

29th April 1884.

No. 7.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER of the CENTRAL PROVINCES for 1882.

1. According to the census enumeration of 1881, the population of the Central Provinces was composed of—

Males	5,801,794
Females	5,703,355
Total	11,505,149

The previous census of 1872 gave a total population of both sexes of 9,251,229, showing an increase in the decade of 2,253,920, or 25 per cent.

But, as the Officiating Secretary to the Government points out, these numbers considerably exceed the "total population under registration," which was 8,802,040 in 1882 as against 7,409,865 at the time of the preceding census of 1872. The increase of registered population has been nearly 16 per cent. in 10 years, and as the ratios were calculated on the population of 1872, the birth-rate under the increased population has suddenly fallen from 48·94 to 41·73 per 1,000, and the death-rate from 32·58 to 29·98 per 1,000.

2. In 1882 the registered births were as follows:—

Sex.	Number.	Ratio per 1,000.
Males	190,466	21·64
Females	176,862	20·09
Total	367,328	41·73

3. The deaths registered during the same year were:—

Sex.	Number.	Ratio per 1,000.
Males	140,521	31·69
Females	123,347	28·24
Total	263,868	29·98

4. The next abstract shows the distribution of births and deaths over the districts :—

Districts.	Population 1881 (under Registration).	Area in Square Miles.	Birth rates, 1882.	Death-rates per 1,000 of Population.	
				1882.	Previous 5 Years.
Saugor	564,950	4,005	48·81	37·27	38·66
Damoh	312,957	2,799	47·28	41·28	37·41
Mawara	205,807	1,176	44·16	27·59	31·90
Jubbulpore	481,299	2,742	43·06	38·58	37·34
Narsinghpur	365,173	1,915	44·23	43·34	34·80
Hoshangabad	488,787	4,437	25·17	29·81	27·33
Nimar	154,677	2,202	45·55	33·55	37·95
Burhanpur	76,446	1,138	33·93	23·34	34·59
Mundla	361,760	4,719	38·34	25·96	37·68
Betul	304,905	3,905	43·27	34·78	31·13
Chindwara	308,388	2,981	45·65	29·30	30·21
Seoni	334,733	3,247	39·33	36·81	29·58
Balaghat	340,554	3,146	39·69	30·06	32·33
Bamdhara	609,279	5,922	41·94	28·34	33·59
Nagpur	697,356	3,786	43·91	28·01	30·24
Wardha	367,221	2,404	39·06	24·64	34·13
Chanda	534,245	10,785	40·89	24·62	30·22
Raipur	1,141,882	5,467	39·92	23·77	35·43
Bilaspur	746,180	3,641	41·12	28·93	35·09
Sambalpur	371,491	1,830	38·66	24·82	25·32
Total for the Province	8,802,040	71,245	41·73	29·98	33·21

These figures refer to the total registering population. Divided between rural and town circles the death ratios stand as follows :—

Districts and Towns.	Population, 1881.	Death-rates per 1,000.	
		1882.	Previous 5 Years.
20 districts	8,054,308	30·47	32·44
72 towns	747,732	27·90	44·14
Total	8,802,040	29·98	33·21

In the 10 years interval 1872 to 1881 it does not appear that any annual estimate of the population was used in calculating the ratios, and hence it would be scarcely worth the trouble to compare the death-rates of 1882 with those of preceding years, were it not that no other data are available. The comparison in the tables already given, namely, an aggregate death-rate of 29·98 per 1,000 for 1882, against the previous five years average of 33·21 per 1,000, is all that need be stated, except that the difference between the two rates must not be taken as a result of sanitary work done.

6. On the general question of registration accuracy there is a remark made by the Sanitary Commissioner that may be quoted, as pointing out a danger which has presented itself in India. He says, "In ordinary years the great difficulty in the way of obtaining accurate returns is that "the reporting officers are often unnecessarily dictated to. When in any circle the number of births "or the number of deaths is a little above or a little below the average, it is too often the practice "to write and demand an explanation, indicating the supposed mistake. When this is done month "after month and year after year, the police authorities are tempted to try to make their returns "agree with the supposed wishes of the Sanitary Commissioner." This is, unfortunately, a Native propensity; but a properly drafted circular, explaining what is actually wanted, and positively forbidding all tampering with the facts on pain of punishment, might possibly lead to greater accuracy in reporting. Explanations of this nature are frequently necessary under all statistical organizations, and in the present case the matter has not been overlooked by the Government, for in cases of doubt a chief constable is deputed to make a house-to-house inquiry when considered necessary. Possibly the method suggested by the Sanitary Commissioner of the North-West Provinces, of receiving the report of births, and, we have suggested, of deaths also, from the head of the family, might meet the difficulty, at least, in time.

7. We shall next give a brief account of the disease history of 1882. The following deaths were recorded under the usual heads, and ratios are calculated on the population of 1881 :—

Diseases.	Registered Deaths.	Deaths per 1,000.
Cholera	11,952	1·36
Small-pox	3,945	0·45
Fevers	152,407	17·31
Bowel complaints	24,639	2·80
Injuries	4,236	0·48
All other causes	66,709	7·58
Total	263,868	29·98

8. Taking each of these death causes in order, we shall begin with—

Cholera, the annual mortality from which for the last 16 years has been as follows:—

Years.	Deaths from Cholera.	Years.	Deaths from Cholera.
1867	253	1875	14,646
1868	7,592	1876	20,124
1869	57,079	1877	3,418
1870	107	1878	40,985
1871	19	1879	27,575
1872	1,592	1880	330
1873	344	1881	9,140
1874	14	1882	11,932

The great mortality of 1878–79 was connected with the famine, and, allowing for these as exceptional years, the statistics show recurring periods of great epidemic prevalence, followed by marked diminution of cholera for a year or two.

9. The report contains a table showing the number of cholera deaths in relation to the year's rainfall, which it is not necessary to give in detail, because any influence exerted by rainfall on cholera is local and temporary, and not general and annual. The lowest rainfall during the 16 years was 29·81 inches in 1868, in which year there were 7,592 deaths from cholera. The highest rainfall was in 1867, with 58·94 inches and 253 cholera deaths. The greatest death-rates of the entire period were those of the famine year 1878, which yielded 40,985 cholera deaths, with a rainfall of 49·31 inches, and the 57,079 deaths of 1869, during which the annual rainfall was nearly the same, viz., 49·38 inches.

10. Cholera was pretty generally diffused throughout the Provinces in 1882, for deaths from it were registered in all the 20 districts, with two exceptions, Burhanpur and Betul, and in 101 registration circles out of 168. But the deaths, as usually happens, took place in a few population groups. In the present case all the deaths were returned from 1,605 groups out of 27,529. And out of 72 towns 31 only returned deaths, 656 in number, or, on an average, a little over 20 deaths per attacked town.

The death-rate for the whole town population was 0·88 per 1,000, and for the rural districts 1·40 per 1,000. The lowest district death-rates of the year were those of Hoshangabad, 0·04 per 1,000, and Sambalpur 0·18 per 1,000; the highest rate, 5·77 per 1,000, was registered in Seoni. A town in Seoni district, Lakhnadon, yielded the greatest death-rate from cholera perhaps on record, namely, 40·74 per 1,000. It has only a small population of 1,350, out of which 55 died of cholera.

11. The following was the monthly incidence of the epidemic of 1882:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	451	July	2,513
February	542	August	3,064
March	186	September	923
April	594	October	265
May	1,236	November	12
June	2,140	December	1

This abstract shows that a wave of cholera passed over the Central Provinces in 1882. In past years attempts have been made to connect the Central Provinces epidemic with that of the endemic area of Bengal by means of pilgrims returning from Cuttack and Juggernauth, and entering the eastern districts of the Province. This idea was not supported by the experience of 1881, and the facts of this epidemic of 1882 show that, wherever the cholera came from, it did not enter the Provinces from the east. The preceding table shows that there were 451 cholera deaths in January, but none of these took place at the eastern extremity of the Provinces. In like manner there were 542 deaths in February, only two of which took place in the East; but still, there was not a single death in the district nearest the endemic area, Sambalpur. It was not until March that Sambalpur yielded six cholera deaths, while the provinces yielded 186 deaths in the same month. Where, then, did this epidemic come from? A map attached to the present report gives the position of cholera as regards the more severely-affected districts, and it appears to show that there were two eruptions of cholera into the Provinces, both from the north. The most severe one entered the northern boundary of the Central Provinces from Bundlecund and from the south-eastern districts of the North-West Provinces, where the disease began to assume an epidemic form in January 1882. The map shows the epidemic in its more severe form as extending right across the Provinces from north to south, with a breadth of about 70 miles, until it entered the Berars. The minor outbreak is shown to have arrived from Chota Nagpur, and to have extended, in a south-eastern direction, to the centre of the Provinces. We have thus two facts presented by this epidemic:—1st, a pretty general diffusion of cholera in a milder form over the area of the Provinces; and 2nd, a distinct invasion from the north in severity along two lines of march.

12. We shall next see what relation these epidemic inroads bore to the cholera epidemic in Northern India in 1882.

Throughout the entire year cholera prevailed all over Bengal as a great epidemic, and 182,352 people died of it, exclusive of deaths in Calcutta. Cholera also existed as an epidemic in the south-eastern districts of the North-West Provinces for the first half of 1882; and in January and February of that year the Sanitary Commissioner had reported 1,172 and 973 deaths from cholera, 2,145 deaths in all, as having occurred in eight districts around Allahabad, lying to the north of the Central Provinces, and at a nearest point distance of about 60 miles. It was in the month of January that the great Allahabad Mela of 1882, described in our Memorandum on the North-West Provinces Report for 1881, was held, at which three millions of people were present; and we shall next examine what was the relation between this fair and cholera, in the region where it took place, as part of the history of the Central Provinces epidemic of 1882.

13. The first case of cholera at the fair took place in a child on the night of 17th January, and the epidemic distinctly showed itself on the 18th and subsequent days. On the 20th January the people began to disperse. But while cholera appeared at the fair it also broke out out in districts outside its influence. Cholera appeared in Sultanpur district on 4th January. On the 10th it was in Banda; on the 15th in Allahabad district, all before it appeared at the fair. On the 20th Partabgarh was attacked, and on the 22nd Fatehpur. Judged by the dates of attack, the fair cholera was part of the general epidemic. But the pilgrims carried cholera away with them from the fair, and died at places along the roads and railroads, without, however, affecting the localities. At a subsequent date the epidemic prevailed severely in Benares district, and crossed the Ganges into Rohilcund, where it occasioned great loss of life before its force was spent.

Pilgrims returning from Allahabad into the Central Provinces were also attacked on the road. It is stated that 95 of them died at Jubbulpore alone. To some extent the experience of pilgrim trains in the North-West Provinces was reproduced in the Central Provinces, but it is important to note as part of the epidemic history that cholera had already shown its presence in these Provinces before it appeared at the Allahabad Mela. The earliest reported case given by the Sanitary Commissioner took place in Kahani circle in Seoni on the 17th January, and it lasted till August. Its time of greatest severity was May and June. It attacked 19 villages out of 185, and occasioned 148 deaths.

This circle lies towards the centre of the Provinces, and 60 miles from the nearest point of the railway. But cholera appeared also at Jabbera, a rural circle in Damoh, 86 miles to the north-west of Kahani, on the 21st of January, on the day after the pilgrims at Allahabad began to disperse. During the month of January there were the following deaths in the Central Provinces within 10 days after the commencing dispersion of pilgrims:—

District.	Total Villages in Districts.	Villages attacked in the Year.	Deaths from Cholera in January.
Saugor - - -	1,333	52	58
Damoh - - -	1,121	293	329
Marwara - -	686	36	18
Jubbulpore - -	1,606	113	35
Narsinghpur - -	983	128	3
Hoshangabad - -	1,344	2	1
Seoni - - -	2,452	252	7

This abstract shows the amount of cholera in the Central Provinces for the week after the fair had completely broken up, and also the villages attacked during the year. The history is an epidemic one, although there is a concurrence of opinion among medical officers that part of the deaths took place among returning pilgrims. The real epidemic, however, did not follow these January deaths. It set in during April, and continued until November. In a preceding table we have given the monthly deaths. The facts, as a whole, appear to point to the following conclusions:—1st, that cholera moved early in the year from Bengal into the North-West Provinces; 2nd, that at the same time the Allahabad Mela was held where cholera appeared among the pilgrims, who also carried cholera with them on their departure; 3rd, that this cholera did not spread beyond the pilgrims; 4th, that of the moving Bengal cholera part passed across the Ganges into Rohilcund, and part moved to the south into the Central Provinces in two columns, one by way of Marwara, and the other from Chota Nagpur to Bilaspur and Raipur. The first column moved into Berar, the second stopped in the centre of the Provinces.

14. We have already seen that out of 27,329 villages, all the cholera deaths of the year were furnished by 1,605. This is one of the facts of which no explanation has yet been given. A year or two ago we expressed a wish that, in marked instances of comparative exemption from cholera, some attempt might be made to solve the difficulty, especially in the towns were good sanitary work had been done. The epidemic of 1882 was a severe one, and yet only 31 towns out of 72 suffered. The total populations of 747,732 yielded 656 deaths, or 0·88 per 1,000, while the more sparse country population of 8,054,308 had 11,276 cholera deaths, or 1·40 per 1,000. Of the towns, 43 per cent.

were attacked, and these yielded 21 deaths per town. The attacked villages were under 5·8 per cent. of the total villages, and the deaths in the attacked villages averaged a little over 17 in each. The facts in either case appear to show a high but limited local intensity. So far as the villages are concerned, there is reason to believe that their sanitary conditions did not essentially vary from those of previous years, and hence the year's experience confirms that of all other epidemics, namely, that some other agency is required to light up an epidemic besides local sanitary defects. This fact is well known, but it is necessary from time to time to refer to it, because of a tendency in some Indian reports to treat sanitary condition as distinctly causative of cholera, *i.e.* without the co-operation of any other agent. One of the civil surgeons in the present Report considers it necessary, in the face of so many observed facts, where sanitary defects have existed in the absence of cholera, to enter a protest against "the argument employed by the supporters of what may be called the 'dirt theory,' that cholera and "small-pox are *caused* by filth, impure sub-soil, impure air, bad drinking water, &c." It cannot be said, so far as existing evidence is concerned, that either cholera or small-pox are *caused*, in the etiological sense, by these local defects, any more than the blowing up of a powder magazine can be said to be *caused* by the presence of the gunpowder. In either case a spark is required to let loose the imprisoned force. Fire may be kept out of a powder magazine, but there are no known means of keeping out the epidemic spark, and hence the only safety lies in getting rid of the magazine altogether. The parallelism may be drawn still closer; for any number of electric discharges may pass through a magazine with perfect safety if there be no powder there, and any ordinary epidemic force may pass over groups of poulation with little or no danger if there be no "filth, impure subsoil, impure air, bad drinking water, &c." But just as no one would argue against the use of lightning conductors for a powder magazine, because the powder had not hitherto been exploded during a thunder-storm, so no argument can be sustained against the most rigid application of sanitary measures in an epidemic country on the ground that some foul villages had escaped cholera or small-pox, while others had unquestionably suffered. Our present knowledge is limited simply to facts, and we do know that the only protection against epidemics everywhere lies in the observance of wholesome conditions of life.

15. Of course, we should all be glad if we could obtain any scientific help in dealing with epidemics. But such help is not likely to come from any of the theoretic quarters dealt with by the Sanitary Commissioner in this Report. We should have welcomed any new facts brought to light during the epidemic of 1882, but, instead of any such help, we are presented with five folio pages of theories about cholera, which are mainly set up to be knocked down. This work is not of the least practical value, and we quite concur in the criticism on it of the Chief Commissioner, who points out "that the "great practical object of that portion of the sanitary report which treats of disease must be to "point out insanitary conditions, to connect disease history with them, and to indicate their remedy."

The opinion of the Sanitary Officer appointed to deal with these conditions is simply as follows: "I have never seen cholera, fever, or small-pox caused by dirt." If this means, not direct causation, but that this officer has never observed any relation between dirt and these diseases, then the question may fairly be asked, What was he appointed for? Had he the necessary qualifications for the work? The expression is probably an unguarded one, for he quotes from the civil surgeon of Wardah, that, in his opinion, "impure air, impure subsoil, and impure water are merely conditions associated "with and favourable to the development of epidemics; they do not in themselves originate "disease." It does not matter whether they do or not. What we complain of is that these conditions are allowed to exist at all, and to be turned in this way into what may very well be excuse for doing nothing. This has occurred before in India.

16. There is not much information in the Report on the main subject of these remarks, namely, the relation of sanitary defects to cholera, but the following may be cited. The Civil Surgeon, Seoni, says, "I noticed repeatedly that in nearly all the villages in which cholera had been "unusually prevalent, it is the custom of the villages to stall their cattle close to and amidst their "dwelling-houses. The stench, principally from decomposing urine, in these villages was very "pronounced." The inference which in this case is made the basis of a theory is denied by the Sanitary Commissioner, because cholera occurs where no cattle are kept.

There appears to have been a considerable amount of inspecting work done of which no account whatever is given in this Report. What is said is usually confined to a single line or two; for example, "Water good, villages not clean, no cholera." "Fairly clean, water good, no cholera." "Fairly clean, no cholera." There are pages of this kind of work, which could just as well have been done in England. Properly speaking, there is no sanitary history of the Central Provinces cholera of 1882. There is plenty of writing, but it is all about generalia; and, moreover, the Sanitary Commissioner appears to have a theory about cholera which does not concern itself with locality. His view, if, indeed, it be the only one he has put forward, is that cholera is due to eating unwholesome rice.

The whole subject is a painful one, and all that can be said is that this year's Report has no practical value whatever, so far as throwing any light on cholera history, or on the far more important matter of showing by what means liability to cholera among village populations can be diminished. What can the Government do when the sanitary administration is in such state that they have to complain that Civil Surgeons evidently report just as if the code (the Village Sanitary Code of 1879) were not in existence? This complaint merely implies that, in the proper sense of the term, there was no sanitary work done by the accredited inspecting officers in 1882.

17. *Small-pox.*—Deaths from small-pox were reported in all the 29 districts of the Central Provinces, with one exception, Chandla, and from 122 out of 168 registration circles. But the attacks

were essentially endemic, as only 1,628 population groups out of 27,529 registered deaths from this disease. Taken by months, the deaths were as follow:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	148	July	519
February	224	August	211
March	389	September	142
April	516	October	74
May	573	November	115
June	764	December	241

The hot weather months were, as usually happens, those of highest mortality. The rural circles, with a population of 8,054,308, yielded 3,700 small-pox deaths = 0·46 per 1,000. The towns, with a population of 747,732, had 245 deaths = 0·33 per 1,000. The town deaths were returned from 27 towns out of 72. A number of the attacked towns had no more than one or two deaths. The most severely affected town was Sehora, which lost 57 of its people out of 5,736, or 9·94 per 1,000. The total small-pox mortality of the year was 2,007 males and 1,938 females, in all 3,945 deaths, or 0·45 per 1,000, against a previous five years' ratio of 1·38 per 1,000. Of the deaths, 1,498 took place in children under one year of age.

The next abstract gives the annual death-rates from small-pox in the Central Provinces for a period of 14 years.

Years.	Death-rates per 1,000.	Years.	Death-rates per 1,000.
1869	3·40	1876	0·51
1870	0·20	1877	0·37
1871	0·20	1878	2·18
1872	0·57	1879	3·44
1873	1·37	1880	0·69
1874	2·38	1881	0·24
1875	3·73	1882	0·45

This table shows that, while small-pox is always more or less prevalent, it takes on the epidemic character in groups of years.

18. The relation of vaccination to small-pox mortality is shown as follows:—

Vaccination for Five Years, 1878–82.		Small-pox Deaths, Five Years, 1878–82.	
Total Number.	Ratio per 1,000.	Total Number.	Ratio per 1,000.
1,627,577	173·49	52,588	5·97

The vaccination report for 1883 is not included in the Report under review. But attention may be directed to the fact that there were 367,328 children born in the year, most of whom ought to have become subjects of vaccination during the year.

19. *Fevers.*—We have the usual caution given by the Sanitary Commissioner under this head, that Indian "fevers" include many other diseases attended by heat of skin besides fevers, and he cites the results of an inquiry made by the Civil Surgeon, Wardha, into 46 so-called fever cases, which showed that,—

13 were cases of ague.
7 of infantile inanition.
5 of worms.
10 dysentery and diarrhœa.
4 chronic bronchitis.
2 measles.
1 rheumatic fever.
1 peritonitis.
1 dropsy.
1 calculus.

To this list of diagnostic errors, the Sanitary Commissioner adds the remark that "In India, by "fever is generally understood malarial fever or ague, and there can be no doubt that this is the most "common of Indian diseases, and the one which carries off the greatest number of people." We may here suggest whether the paroxysmal test, if applied to the reporting of fatal fever cases instead of

the heat test, might not result in better classification. If ague is the most common of Indian death causes, it ought to be easily distinguishable by its paroxysmal character. There are however, other fevers mentioned as occurring among the Native population, such as "thermic fever," "typhus fever," "typhoid and relapsing fever." "Thermic fever" attacks suddenly, with well marked head symptoms, and is frequent and fatal in hot weather. "Typhus" is of gradual onset, with head symptoms, and a rash like flea-bites, followed by petechiæ. "Relapsing fever" is of sudden onset, with hepatic and splenic symptoms, and tendency to hemorrhage.

"Typhoid fever," the Sanitary Commissioner says, "has been persistently misunderstood," and then follows a statement which we must notice, although with deep regret, as to the cause of this most formidable and fatal of Indian fevers. He says he believes "that it is a very infectious disease, occurring once in a lifetime, identical with distemper in the dog, and almost invariably caused in a human being by infection from a dog ill of distemper;" which infection he represents as being conveyed from distempered dogs in barracks to young soldiers there, and he supports this view by quite untenable statements, the practical result of which, if true, would be to show that, so far as this fever is concerned, neither soldiers' ages, nor local sanitary defects, nor climatic causes could have any influence on the prevalence or fatality of the disease, either in India or, indeed, anywhere else.

Much more than this might be abstracted about it from the Sanitary Commissioner's report, but what has been said will be sufficient to show that, if this view is really put forward seriously, it must be ranked among those disease theories which have hitherto obstructed sanitary work everywhere. We have no mission to interfere with private opinions on medical subjects, but we have a perfect right, for practical purposes, to ask for specific cases where typhoid fever has been traced to distempered dogs, and where the destruction of barrack dogs has put an end to enteric fever among young soldiers. Without this proof this dog theory, and, indeed, all theories without experience to support them, have no more *raison d'être* than any village theory attributing cholera and fever and small-pox to the anger of local gods or demons.

20. But, to return to the fever history of 1882, we find the following facts regarding its monthly incidence during this year:—

Months.	Deaths from Fever.	Months.	Deaths from Fever.
January	10,805	July	12,311
February	9,876	August	14,969
March	10,580	September	16,445
April	10,813	October	16,475
May	12,127	November	14,882
June	10,695	December	12,429

These monthly deaths show the influence of drying up of the ground and of low temperature on the amount of fever.

Fevers in 1882 prevailed all over the Central Provinces. Every registration circle returned fever deaths. Fever deaths were reported from 21,204 villages out of 27,529. The country registration circles reported 144,230 fever deaths, or 17·91 per 1,000 of the rural population. All the 72 towns returned deaths, 8,177 in number, or 10·94 per 1,000. The fever death-rate for the whole province was 17·31 per 1,000 against a previous five years' ratio of 20·68 per 1,000.

The fever-rate varied considerably in different districts. The lowest rate of the year was returned from Nagpur, namely, 5·24 per 1,000, Wardha returned 9·17 per 1,000, and Sambalpur 8·20 per 1,000 against a previous five years' average of 8·04 per 1,000. We shall refer afterwards to the last of these cases. The highest rate of the year was 29·60 in Narsinghpur district. Fever death-rates varied to a much greater extent in town than in country circles. In several towns in Nagpur district the fever deaths were under 3 per 1,000. In two towns the rates were under 1 per 1,000. In Nagpur town itself, with its population of 98,299, the fever rate was 3·26 per 1,000. Kamptee in the same district returned 23 fever deaths out of a population of 50,987, or 1·24 per 1,000. Most of the higher rates were returned from less populous towns. Seoni, out of a population of 6,928, yielded 225 fever deaths, or 32·15 per 1,000. The highest fever-rate of the year, 35·04 per 1,000, was returned from the small town of Mahrajpur, but it has only 1,541 inhabitants.

21. The local fever-rates vary to a much greater extent than do the annual rates, as is shown by the following ratios for the last nine years:—

Years.	Fever Deaths per 1,000.	Years.	Fever Deaths per 1,000.
1874	15·90	1879	18·84
1875	16·26	1880	18·46
1876	20·22	1881	19·42
1877	17·70	1882	17·31
1878	29·50		

The year 1878 was the famine and scarcity year, which accounts for its higher rate.
As regards the varying local rates, the present report contains no account of their causes.

22. *Bowel complaints.*—In 1882 there were returned 24,639 deaths under this head, equal to a death-rate of 2·80 per 1,000. The preceding five years' rate was 2·75 per 1,000, so that the mortality from this cause is tolerably constant. All the circles of registration returned deaths in 1882, but out of 27,529 villages all the deaths were reported from 8,336.

The monthly mortality was as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	1,616	July	2,342
February	1,714	August	3,313
March	1,698	September	3,080
April	1,828	October	2,313
May	1,997	November	1,736
June	1,697	December	1,405

The hot and rainy months are apparently those when bowel diseases are most fatal.

23. The extent to which bowel complaint mortality prevails differs in different districts. In several districts the rate is under one or two per 1,000. The highest rate was 12·38 per 1,000 in Sambalpur district against a previous five years' average of 10·63 per 1,000. This high rate is persistent, and led us in a former memorandum to suggest some inquiry into its cause, with reference also to another peculiarity about its persistently low fever-rate of about 8 per 1,000. We further suggested a comparison between the rates from both causes in Sambalpur and Bilaspur, in which latter districts the rates appeared to be reversed. The problem will be understood from the following abstract, premising that both districts are in the Mahanadi division:—

Districts.	Ratios per 1,000 Fevers.		Ratio per 1,000 Bowel Complaints.	
	1882.	Five Years' Average.	1882.	Five Years' Average.
Sambalpur	8·20	8·04	12·38	10·63
Bilaspur	24·16	26·96	0·40	0·58

The following appears to have been the result of the inquiry:—

(1.) Registration is conducted in the same way in each district.

(2.) The people in Sambalpur district depend for their water-supply on more surface tanks supplied from unprotected surface areas, and the tanks so supplied are used for all purposes, "ablution, drinking, watering of cattle, and washing of clothes." The tank supply falls low, and becomes impure, in the dry weather. These bowel diseases are, moreover, related to great prevalence of worms among the people, a fact which points to impure water containing ova of worms as a probable cause of the whole class of diseases.

It is admitted, however, that further inquiry is necessary.

(3.) As regards the fever. Sambalpur occupies a comparatively unfertile tract with light soil and underlying silicious highly indurated rocks, while Bilaspur is "a damp country, the very place where one would expect malarious fevers."

There are many wells besides tanks in Bilaspur, but in Sambalpur water is chiefly derived from tanks.

These facts appear to point to the causes of difference in disease prevalence in the two districts.

24. *Injuries and all other diseases.*—Under the first head are returned 4,236 deaths, of which 648 were suicides, and 1,287 deaths from snake-bite and wild beasts. Under the head of "all other diseases" are included 66,709 deaths, of which a number were reported as having been due to measles, pleurisy, &c.

25. *Sanitary Works (Civil).*—Abstracts of Civil Surgeons' reports show steady progress in town improvements, so far as any account of such improvements is given. But for 19 towns only is there any account of the municipal income and expenditure. Details are not given, but it is stated that such and such percentages of income were spent on conservancy. The lowest amount under this head is 3·81 per cent. for Jubbulpore. The highest is 69·09 per cent. in Balaghat. A few notes for each town will show the nature and progress of works in hand.

In *Nagpur*, water distribution to private houses from the Ambaghari reservoir was being extended. Conservancy arrangements were being improved, and the surface drains deepened and cleansed. Drainage of the civil station was being improved. This town has been undergoing improvement for a number of years, and has an excellent water-supply laid on by gravitation. Its population in 1881 was 98,299, and its death-rate in 1882 was 30·76 per 1,000, of which 0·89 per 1,000 was due to cholera, and 3·26 to fevers. It has only surface drainage as yet; but conservancy appears to be well attended to.

Wardha.—The Hinghanghat waterworks were nearly ready for opening.

Balaghat.—"A very fine tank is being built at head-quarters." A statement is made about the head-quarter town which may be introduced. Balaghat district had a death-rate from cholera of 2·18 per 1,000. There was no cholera at the station where the Deputy Commissioner "made "arrangements to prevent the lower classes from polluting the drinking-water supply."

Jubbulpore.—The water scheme for this town "has been pushed on vigorously." This town of 60,181 inhabitants has been under active improvement, and in 1882 its total death-rate was 24·94 per 1,000, of which 0·40 was due to cholera, and 11·93 to fevers. The corresponding district rates were 2·80 from cholera, and 17·94 from fevers.

At *Saugor* the water-supply was being improved. Similar improvements had been carried out at Damoh, and surface drains had been formed.

At *Seoni* considerable improvements in water-supply had been effected, and filtered water was in use. An unwholesome irregular tank had been lined with stone, and greatly improved. Drainage and conservancy have also been attended to. This town had an old system of covered surface drains, which were being abolished, and open saucer-sectioned drains substituted, an arrangement much better adapted for purposes of health. It is always necessary to provide water for washing out surface drains in towns. Many open pits and hollows have been filled up. This town lost 5·51 per 1,000 from cholera in 1882, while the district had a cholera death-rate of 5·77 per 1,000. The chief death cause in Seoni, both town and district, is fever, from which the town had a death-rate of 17·38, and the district of 22·65 per 1,000. These figures may shew the direction in which work should be extended. The total death-rate in 1882 was very high, namely, 37·26 per 1,000.

It is unnecessary to pursue these details further, except to state that the main direction which public health works appear to have taken has been the very important one of improving the water-supply. From a table in the Report it appears that in the course of the year 54 wells were repaired, and 226 new wells constructed. These figures, of course, represent a single year's work, one of many preceding years, but the total improvements are very small when compared with the number of villages. None of the year's reports contain any account of the internal sanitary economy of villages or village houses, or of efforts made by Civil Surgeons or by the Sanitary Commissioner to forward village improvements under this head of the Report.

26. We have already alluded to the sanitary statements under the head of cholera. No doubt inspecting work was done; but everything depends on its object, and on the manner of doing it, and the final result is that, without any indication of a single village compound or house having been examined with ordinary sanitary care, we are told that "defects there are, it is quite true, such as bad "water-supply, in many instances cow dung in greater or less quantities always present, but the foul "smells and human excreta in quantities in every direction so often described were very generally "conspicuous by their absence." Where were they, if not outside the houses? And the final result is that "any attempt to introduce compulsory conservancy or sanitary rules in the rural districts, "even if practicable, would be attended with great expense, would inevitably fail, and would in "every sense be an unmixed evil." Of course there are rules and rules, and more ways of administering rules than one, but a general statement such as this can lead to only one conclusion, and this is, that the present sanitary organization can be of little use in these Provinces.

A somewhat similar remark is applicable to the manner in which the vaccination service has been used for instructing the people. It was never contemplated that all vaccinators, merely because they were such, should be constituted sanitary officers. Men of the class of superintendents were considered the most likely to be useful in such work. But it appears as if no training or care had been exercised in the matter, and the vaccinators have hence been disliked by the people.

27. We conclude these remarks with an expression of regret at having been obliged, in the sanitary interests of these Provinces, to have made them. We can only deal with the Civil Surgeon's reports as they have been presented to us, in abstract, in the hope that as a whole, if we had had them before us, we might have been able to have formed a more favourable estimate of the year's work.

As this Report has come before us we can arrive at no other conclusion than that, as already stated, its sanitary contents are without value.

The Officiating Secretary to the Chief Commissioner, as we have said, has expressed regret that the Sanitary Commissioner has in no part of his Report referred to the Village Sanitary Code of 1879, which is the ground of village sanitary work, and "Civil Surgeons evidently report just as if the code "were not in existence. In not a single instance does Mr. Jones find a Civil Surgeon reporting that "such and such a rule has been neglected." And we adopt the views of the Chief Commissioner that this code, with such improvements as experience may dictate, "should be the foundation of all village inspection," and consequently of all village sanitary work. For it never should be forgotten that Indian epidemics have their home in the present foul and neglected state of the villages of India, and that the entire cost of the sanitary service has been incurred by Government for no other reason than to aid in rendering all population groups, as far as practicable, secure against epidemic invasions.*

22nd July 1884.

No. 8.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER of the HYDERABAD ASSIGNED DISTRICTS for 1882.

1. All the statistical data in this Report have been calculated on the census population of 1881, which consisted of—

Males	1,380,492
Females	1,292,181
Total	2,672,673

The previous census of 1867 gave a population of 2,227,654, so that in 13 years there had been an increase of 445,019, or in the ratio of 19·98 per cent. for the whole period, or about 1·5 per cent. per annum. This rate of increase is not abnormal, and ought to represent the excess of births over deaths in a stationary population in health. The difficulty, however, is to ascertain what this excess really is, on account of the great diversity in the annual births and deaths registered in different years. The years of highest registration numbers were 1881 and 1882, and, taken on these two years, the actual increase of population would be about 400,000 in the period. But the population is liable to additions from immigrants, of whom 435,933 entered Berar in the 13 years. It is possible, also, that numbers of people may have left the districts and settled elsewhere. If this were so, the statistics for the assigned districts would be reliable for practical purposes, and the ascertained addition would be the normal one. There appear to be no means of coming nearer the actual causes of increase but the census numbers of 1881, and the latest registration returns may be safely used for purposes of comparison.

2. The population totals already given include Melgat, but the number actually furnishing returns of births and deaths in 1882 was 2,630,018, and from among this number there were registered in 1882, of—

Births	110,454
Deaths	77,214

The births were 42 per 1,000, and the deaths 29·4 per 1,000, of the population. The births exceeded the deaths by 33,240, or 12·6 per 1,000, which, it will be seen, is a little under the average 13 years' increase, which was 1·5 per cent. per annum.

3. The next abstract shows the distribution of births and deaths in the districts:—

Districts.	Ratio per 1,000 of Population.					
	Rural Circles.		Towns.		Total.	
	Births.	Deaths.	Births.	Deaths.	Births.	Deaths.
Amraoti	43·9	31·3	35·3	30·0	42·7	31·3
Ellichpur	42·2	30·3	38·4	26·2	41·4	29·4
Wun	39·5	26·3	—	—	39·5	26·3
Basim	41·5	23·7	32·8	22·2	40·4	23·7
Akola	40·9	33·9	35·0	23·7	41·5	33·9
Buldana	45·5	28·3	35·2	28·6	45·0	28·3
Means	42·2	28·9	35·3	26·1	43·2	28·8

There are 29 towns in the districts, and 133 registration circles. These ratios show that, either from differences in registration accuracy, or from local causes, the rural death-rates exceeded the town rates by 2·8 per 1,000. The total mean death-rate in this table is 0·6 per 1,000 under the rate given in the Report.

The Sanitary Commissioner has discussed the subject at greater length, but our present purpose is limited to the year's deaths and their removable causes.

4. *Death causes.*—These come under the following heads:—

Diseases.	Total Deaths.	Deaths per 1,000 of Population.
Cholera	3,573	1·4
Small-pox	369	·1
Fevers	39,340	15·0
Bowel complaints	13,546	5·2
Injuries	1,003	·4
All other causes	19,383	7·4
Total	77,214	29·4

This statement includes the population as a whole, but the census enables us to show the death-rates among different classes, as follows:—

Classes.	Population.	Deaths registered.	Deaths per 1,000.
Christians	1,330	13	9·8
Muhammadans	186,033	5,706	30·6
Hindus	2,311,614	60,380	26·1
Other classes	131,041	11,115	84·8
Total	2,630,018	77,214	29·4

The death causes are not given by classes in the returns.

5. We shall next discuss the facts connected with each death cause, beginning with cholera.

The following abstract shows the annual cholera deaths in comparison with the total annual deaths registered since 1868:—

Years.	Deaths, all Causes.		Deaths from Cholera.	
	Total.	Deaths per 1,000.	Total.	Deaths per 1,000.
1868	86,743	19·1	5,447	2·9
1869	47,338	22·8	10,947	5·2
1870	53,872	24·6	504	0·22
1871	38,725	17·7	581	0·2
1872	81,108	37·1	1,578	0·7
1873	49,896	22·8	—	—
1874	60,797	27·9	2	0·0009
1875	88,068	40·3	22,465	10·2
1876	69,832	31·9	2,682	1·2
1877	61,459	28·1	842	0·4
1878	178,404	81·5	34,306	15·6
1879	51,907	23·7	223	0·1
1880	51,725	23·6	1	0·0004
1881	76,661	29·1	3,404	1·3
1882	77,214	29·4	3,573	1·4

This abstract shows deficient registration generally in the earlier years, but approximately accurate registration of cholera deaths. The year of maximum mortality, 1878, was a year of great scarcity of food, and it is certain that it was the year of greatest cholera mortality. This epidemic, aided by want of food and the presence of local insanitary conditions, cut off 34,306 people, or a death-rate of 15·6 per 1,000. Cholera in Berar is a disease of sudden and violent outbursts and rapid subsidences, but, allowing for all this, it is by no means the most fatal epidemic incident to the province. In 1882, for every death from cholera there were above 10 deaths from fever, and during the entire 15 years, 1868 to 1882 inclusive, out of 1,033,150 deaths, 86,556 were from cholera, 43,939 from small-pox, and 473,015 from fevers. The relative mortality will be better shown by comparing the aggregate death-rates from epidemics for 14 years, 1868 to 1881, as follows:—

	Aggregate Death-rates per 1,000.
Cholera	38
Small-pox	20·78
Fever	195·9
Bowel complaints	86·2
All other causes	430·2

The reason for adducing these facts is simply to show that cholera epidemics are by no means the important death causes which their sudden fatality would lead us to expect, that they occupy an important but subordinate position in the epidemic history of Berar, and that the improvement of public health includes the mitigation of other fatal diseases besides cholera. Sanitary history concerns itself not only with the present, but with the past, in order to be better able to comprehend the extent and nature of its future work.

6. But to return to the cholera epidemic of 1882, from which 3,573 people died, the following was its monthly distribution:—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
January	14	July	26
February	—	August	1,868
March	—	September	1,116
April	—	October	321
May	—	November	128
June	—	December	100

The 14 deaths in January occurred in Wun district, which has a population of 392,102. The other five districts escaped until July, when the true epidemic began, and it then affected all the districts. To all appearance the 14th January deaths belonged to the previous year's cholera, and the real epidemic would pass over to 1883.

7. Cholera mortality was divided between rural districts and towns in the following proportions:—The district population numbers 2,491,640, and it yielded 3,375 deaths from cholera in 1882, equal to 1·4 per 1,000. The towns returning cholera deaths had a population of 138,378, and registered 198 deaths, and a death-rate of 1·4 per 1,000, the same rate as ruled in the country districts. Both districts and towns showed considerable difference in the rates. In the former the rates were between 0·4 per 1,000 in Ellichpur, and 2·4 per 1,000 in Amraoti. Deulgaon Raja town had the lowest town death-rate from the epidemic, namely, 0·3 per 1,000, and Amraoti town 3·7 per 1,000, the highest.

The cholera of 1882 was very generally present over the provinces, for deaths were returned from 111 out of 133 circles of registration. There was, however, the same disposition to attack specific localities, as is shown by the fact that the cholera deaths all took place in 481 population groups, out of a total of 5,328 in the province.

8. It has been already shown that the epidemic really began in July, but that there were 14 deaths in January 1882. These 14 deaths took place in two registration circles in Wun district, contiguous to those parts of the Central Provinces where cholera prevailed epidemically in 1881. The affected circles, were, in fact, part of the same epidemic region. There was next an entire absence of deaths from cholera until the 20th July 1882, on which date the disease reappeared in another rural circle in Wun district, and within a few days thereafter it attacked other circles in Wun, Buldana, Akola, and Amraoti districts, none of the attacked points having been contiguous to Wun, but lying in the course which the epidemic was apparently following south-westward. On this subject the Sanitary Commissioner remarks, this westward movement of the epidemic was "unusual, and not "in accord with experience which would show that the disease, as a rule, always prevails in the "Khandeish district of Bombay Presidency to the west before it reaches us." The history of this epidemic presents points of considerable interest and importance, because the first cases appear to have been carefully investigated at the time, simply to arrive at the truth about them, and it may be useful to abstract the leading results obtained as follows.

9. As stated above there were 14 deaths in Wun district in January 1882. Of these the last death took place on the 21st January, the epidemic in this district having passed over from December 1881. It is remarkable that this district furnished a similar epidemic history in 1882. The first case of the true epidemic took place on the 20th July 1882, and during the remainder of the year the monthly deaths in Wun district were as follow:—

	Deaths.
July	8
August	309
September	317
October	40
November	44
December	28

The disease passed over into January 1883, and ended on the 22nd of that month, after having caused 30 additional deaths, so that we have here a distinct seven months' epidemic, covering a well defined area. It attacked 19 circles in Wun district out of 26, and 106 villages out of 1,139. The first fatal case in this district occurred on 20th July, and the next case on 25th July. It is necessary to keep these dates in mind, because the 20th of July case has an importation history, to the proper estimation of which dates are of importance.

On the 21st July, the day after the first Wun case took place, cholera appeared in Buldana district, in Chikhli rural circle. This circle is 110 miles west of Kulgaon and Digras circles in Wun, where the January cases took place, and 130 miles westward from Kalamb and Nandura rural circles, where the first cases took place in Wun district on the 20th and 25th July, the former of which was the imported case. But besides this, on the 23rd July the first case in Akola district took place in Shegaon rural circle, 100 miles from Kalamb in Wun, and on the same date the disease appeared in Takulkheda circle in Amraoti district, 60 miles to the north-west of the supposed imported case.

These facts clearly show that cholera was spread over nearly the entire area of Berar at the time the importation took place, and by themselves they would apparently class the imported case among coincidences, for it is quite certain that the subject of this case was not the only one who had arrived from the Central Provinces, but she was apparently the only arrival who was attacked.

10. Let us next see what was the nature of the locality at which she arrived from the Central Provinces. It is thus described by the civil surgeon:—"On reaching Ashti I observed the road "from Madin, a bazaar village, was occupied by a running stream, the water of which entered the "village nullah. On each side of this stream almost the whole village resorted for purposes of "nature; dead animal remains, bones, ordure, &c., were washed down this stream into the nullah, "which, when overflowed, filled two pits immediately behind the Mahar's huts. One pit contained "all the refuse of the town, animal and fæcal matter, the other pit contained festering heaps of "rubbish collected for burning bricks." To this account the Sanitary Commissioner adds, "The "cases first attacked lived near these pits, the stench from which was so intolerable that one could

" scarcely stand to windward of them. The water-supply of these first cases was from a well polluted " with the overflow water of the pits." We have in this importation case two preliminary facts, namely, epidemic extension over the country, and local conditions quite sufficient to supply the spark required to light the fire. Let us now state the importation case.

11. A Mahar woman, an inhabitant of this village of Ashti, "had been to Nagpur in the Central " Provinces, and returned on the 19th (July) (her husband having brought her by forced marches " a distance of about 70 miles). On the day following her arrival in the village she was seized " with purging and vomiting, and died the same night." We have here another predisposing condition added to the history, namely, fatigue, and the Sanitary Commissioner states that "there was no evidence that cholera was prevailing at Nagpur at the time." On the 25th July, the woman's son-in-law and his child, aged four years, were attacked and died. "The disease then spread throughout the village, attacked 97 persons, and caused 47 deaths."

The opinion that this woman's case was imported, and was the cause of the village outbreak, does not appear to have been held by any one except by the villagers.

In Nandura circle the village of Surwul yielded the second case of the year's epidemic. It lies 14 miles from Ashti, and there was no communication between the cases. The locality where this second case took place is described by the Sanitary Commissioner as follows:—"The streets were " found very clean, but in the compounds of houses were cesspools containing fæcal matter, emitting " offensive smells, and about the houses were decomposing dung-heaps. The village had been " flooded by heavy rains, and the overflow had passed into the wells, contaminating the drinking " water."

There is nothing peculiar in the facts. Wun district was invaded by cholera from the east, and there is no proof that the disease was imported by any one. The history merely shows that the first epidemic case occurred on 20th July under marked unwholesome local conditions.

12. As already stated, the second case took place next day at a distance of 110 miles in Buldana district, in Chikhli village, where a girl 11 years of age was attacked. This case was followed by others, as in the Wun example. "The civil surgeon who visited the village reported that the " origin of the case was indigenous, and that there had been no communication between these five " cases, who were of different castes and lived far apart."

The sanitary state of the village is described as follows:—"The general cleanliness of the village " is satisfactory, but the houses are terribly damp. The late unusually large rainfall and the situation " of the village in a basin prevents sufficiently quick surface drainage, although there is some attempt " at a system of drains." These Buldana cases proved the presence of cholera over the district, and the Government discouraged the holding of Deulgaon-Raja fair in consequence, but as the people nevertheless showed no disposition to keep away from it, steps were at once taken to place the locality in as good a sanitary state as possible before the people arrived, by active conservancy, providing proper latrines, and protecting watercourses. Over-crowding was prevented, and a cholera hospital provided. The usual attendance at the fair has been from 80,000 to 150,000, but on the present occasion the gathering "was the largest that has taken place for several years."

Only one case of cholera took place at the fair, which is held generally for about three weeks before the end of October. But it did not occur until the 31st October. There was a case in a man who was taken ill with diarrhœa on the road to the fair, and this became developed at the fair into cholera, from which the man recovered.

"Here," says the Sanitary Commissioner, "were two cases of epidemic cholera in the very midst " of a large concourse of people, yet though the cholera influence was present in the place, either at " the time or imported by these people, no spread of the disease occurred."

13. The first point in Akola district where cholera appeared was in the village of Gavan, in the Shegaon circle, on the 23rd July, three days after the first Wun case; it then attacked the surrounding villages and the town of Akola itself. There was no evidence whatever of importation, and it was an exception to find more than one case in a house "although as many as five slept and lived in the same room."

14. The fourth of these simultaneous cholera outbreaks was at Sirala village in Amraoti district on 23rd July. The patient, a man, was taken ill while working in his field. The disease then extended in the district, and was attributed by the people to a man who had not suffered, but was supposed to have been in contact with affected persons at Pandharpur, in Bombay, where cholera existed. But it turned out that there had been no cholera at this place.

The sanitary condition of the village where the first case took place "was very bad. Manure heaps " in and around the village, which was damp and dirty, with rain-water in pools and in the streets " and lanes. In front of the house of Jeysing, the first case attacked, there was a foul smelling water " hole, or, as described by the hospital assistant, a long ditch full of rotten water, cow-dung and " grass."

The next case took place in a village 12 miles away, and was also a local one. The village where it occurred is situated "on an elevation and near a river, with gutters for streets and dung-hills for " squares. The inside of the court-yards are also receptacles for filth. Near the well from which " the drinking water was obtained was a swampy dung-hill, the water from which must percolate " into the well."

15. We have given these first cases of four simultaneous outbreaks of cholera at four different points of these provinces many miles away from each other, because they show the absolute necessity of a careful inquiry into first cases, and the great advantage which accrues from following this course,

instead of trying to account for the facts on any general theory. If the first report of importation had been accepted as ground of action, then the remedy was unquestionably such a quarantine as would have stopped all intercourse, and the real facts and dates, together with the insanitary conditions under which the affected villages suffered, must have been ignored and indeed unknown. Now everything is plain enough, and we know that the most perfect quarantine measures could have effected not the least good; for the disease was already above 100 miles from the point where these measures should have been applied. And, moreover, we know what were the local conditions under which the disease swooped down on the affected localities, while the experience of Deulgaon-Raja fair has shown how cholera was kept from extending among a great concourse of people, by timely application of simple common sense sanitary proceedings. The practical result, therefore, is, that these poor people should be saved from similar visitations by having their villages and houses cleansed and kept clean, and their water-supply protected from pollution.

16. It is not necessary to discuss the cholera history further, because these first cases and their surroundings are typical of the remainder, and point to the same remedial measures, and we shall conclude these remarks by citing the last opinion on the subject, which, unfortunately for Indian sanitary work, we shall ever receive from Dr. Little:—"Putting aside, then, all theories as to the "origin and propagation of cholera, it must be admitted, in the light of the above facts, that clean- "liness, pure air, pure water, and good drainage are the most likely preventives we can employ "against this terrible disease, which, when once it has seized upon the human body, runs its own "course irrespective of any known remedy or reputed specific."

17. *Small-pox.*—Increase of small-pox deaths co-existed with decrease of deaths from cholera, and the following abstract shows that towards the end of 1882 small-pox was assuming an epidemic character, instead of its usual summer increase:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	21	July	29
February	22	August	21
March	42	September	5
April	30	October	10
May	17	November	28
June	15	December	122

The total year's deaths were 369, of which 231 took place under 12 years of age, and 128 under one year. The death-rate, 0·1 per 1,000, was equally divided between males and females, and it was exactly one-tenth of the preceding five years' average rate.

Small-pox existed in all the six districts during some parts of the year, but in one district, Akola, every month furnished deaths. Of 133 circles of registration 40 yielded deaths, but all the deaths were returned from no more than 95 villages out of a total of 5,238 in the provinces.

Divided between town and country districts small-pox was fivefold more fatal in the former than in the latter. The town rate equalled ·5 per 1,000, and the country rate ·1 per 1,000.

18. For a number of years past considerable progress has been made in extending vaccination among the people, and the next abstract enables us to compare the small-pox mortality with the vaccination.

Years.	Small-pox Death-rate per 1,000 of Population.	Ratio per Cent. of successful Vaccinations to Births.
1869	3·6	24·6
1870	·63	13·2
1871	·20	29·2
1872	3·8	38·5
1873	3·8	58·5
1874	·5	41·6
1875	·4	58·5
1876	·2	63·7
1877	2·9	77·6
1878	2·7	81·1
1879	·03	71·9
1880	·02	73·8
1881	·1	—
1882	·1	—

This abstract shows that of recent years small-pox has been less fatal, while vaccination has been considerably extended. The total vaccinations during the last 14 years have amounted to 642,431, out of a population of about 2½ millions; but the proportion of different ages vaccinated is not stated. The death-ratios at different ages were 62 per cent. between 1 and 12 years, and 3 per cent. over 12 years. This result appears to show that there is room for a large increase of vaccination work at the younger ages. The preceding abstract shows two years of low mortality, following one year,

1869, of high mortality; next two years of high mortality, followed by three years of low mortality; then follow two epidemic years, during which the death-rates had fallen, and then four years up to 1882, during which the small-pox death-rate was lowest of all. It appears probable that part of the decrease may be due to vaccination; but the Sanitary Commissioner very properly gives a caution against assuming that vaccination can stay an invading small-pox epidemic, which, "like a cholera epidemic, will follow its own course." Vaccination, so far as can be judged from Indian experience, is only one sanitary measure among many others which are needed to diminish the liability of the people to epidemic diseases.

19. *Fevers.*—In a preceding table we have stated the fever deaths in the provinces at 39,340, equal to a death-rate of 15 per 1,000 of the population, or more than half the total mortality. The deaths from fever among males to the corresponding deaths among females may be taken as 21 to 18. As usually happens, all the districts returned fever deaths, as did also all the 133 registration circles. But all the population groups did not register fever deaths, although 4,207 of these groups out of 5,238 did so. The registered fever death-rate in the country circles was 15·1 per 1,000, and in the towns 12·6 per 1,000, a difference which may possibly admit of being accounted for by better diagnosis in the town groups. Any way the fever registration cannot be depended on, for reasons we have often stated; namely, that fatal diseases with heat of skin are often entered under the fever heading. There can be no doubt, however, as stated by the Sanitary Commissioner, that malarial fever is the chief death cause in Berar as elsewhere in India.

20. Fever death-rates vary considerably in different districts, as will be seen by the following facts:—

Districts.	Fever Deaths per 1,000.	
	2. 188	Previous Five Years.
Amraoti	14·9	17·5
Ellichpur	15·3	18·8
Wun	21·3	20·1
Basim	10·0	11·7
Akola	16·4	19·0
Buldana	11·2	14·7
Total	15·0	17·1

There are obviously persistent differences in fever death-rates in different districts, and such differences form an important basis on which to rest local sanitary inquiries. There must be reasons, climatic, topographical, and local, for the differences, and we would suggest, by way of trial, an exhaustive local examination, engineering as well as sanitary, into the causes of such differences in rates as exist in Wun and Basim, for example.

Similar differences present themselves in the towns whose average fever-rate is 12·6 per 1,000, while the town rates vary between 2·8 per 1,000 in Basim town, with a population of 11,576, and 25·9 per 1,000 in Akot town among 16,137 people. There must be reasons for all this, and upon discovery of these reasons efficient sanitary work to a large extent depends.

21. As a contribution to the discussion of climatic causes, we shall here extract the monthly elements of climate for the whole area of Berar, and place with them the monthly deaths from fever and cholera.

Months.	Temperatures.			Rain.	Cholera Deaths.	Fever Deaths.
	Max.	Min.	Mean.			
				Inches.		
January	83·5	56·4	69·9	·74	14	3,176
February	85·8	58·1	71·9	—	—	2,752
March	96·3	69·0	82·9	—	—	3,020
April	69·3	55·1	62·2	·03	—	3,187
May	102·0	77·2	89·6	·23	—	3,169
June	88·1	71·6	79·8	11·38	—	2,110
July	80·3	69·9	75·1	13·15	26	2,519
August	82·8	69·3	76·05	4·99	1,868	4,182
September	83·6	69·7	76·6	7·91	1,116	4,763
October	87·8	65·3	76·5	·10	321	3,680
November	81·0	59·1	70·05	·96	128	3,563
December	82·4	56·4	69·4	—	100	3,219

These average climatic data appear to be scarcely sufficient to account for the statistical facts. It is true that increase of fever followed increase of rain, and continued into the drying-up period of the year, but as regards cholera, we have a distinct epidemic outburst during the rain, which continued after any effective rainfall had ceased; but these climatic data will not account for the very various fever and cholera death-rates in different districts and towns. The presumption, therefore, is that local peculiarities of rainfall and topography lent their aid in causing different

local death-rates. There is a diagram in the Report showing the relation of rainfall in inches to the monthly fever deaths in each district, but the monthly ratios to population are the data required. All we can do is to call attention to the facts, and suggest local inquiry.

22. The next abstract shows the annual fever mortality from 1868 to 1882.

Years.	Fever Deaths.	Years.	Fever Deaths.
1868	10,936	1876	39,875
1869	12,917	1877	34,453
1870	23,023	1878	85,260
1871	18,125	1879	32,475
1872	31,853	1880	31,027
1873	19,242	1881	41,681
1874	26,732	1882	39,340
1875	26,076		

The great fever death-rate of 1878 was connected with the famine. There is an apparent increase in the later years above the average fever mortality, but this is no doubt partly due to improved registration.

23. We shall return to the subject of local causes. But in the meantime the following remarks of the Sanitary Commissioner will give a general idea of what they are:—"Our Indian fevers are "most prevalent after heavy rains have water-logged the subsoil, . . . and for which the "remedy is drainage. In some of our large towns drainage schemes are in progress, and will be "urged on to completion. In our *smaller* towns and villages, however, but little has yet been done "in this direction. For villages a deep cutting, to answer as a drainage channel where water is "likely to lodge, is what has been recommended, and though the people could do this themselves, "still it requires to be done under direction."

24. *Bowel complaints.*—Fatal cases registered under this heading are still subject to important errors in classification, as has been hitherto the case, and the returns can be accepted as only partially correct.

The monthly deaths in 1882 were as follow:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	829	July	1,159
February	791	August	2,427
March	797	September	2,077
April	784	October	1,242
May	919	November	966
June	704	December	851

The total registered deaths from "bowel complaints" (chiefly diarrhœa and dysentery) were 13,546, or 5·1 per 1,000 of the population, exactly the same ratio as ruled during the preceding five years. It would appear as if a certain average error in diagnosis had established itself, for these diseases showed very different ratios of mortality in different districts. Deaths from them were returned from all the districts, but the ratios differed from ·6 per 1,000 in Wun district to 8·3 per 1,000 in Akola district, which last had a death-rate during the previous five years under this head of 9 per 1,000. These simple facts suggest the necessity of local inquiry. There must be some reason for the differences which have prevailed for many years. If these diverse death-rates are due to errors in diagnosis, it would at least be advantageous to be informed in what the error consists.

Out of 133 registration circles bowel complaint deaths were returned from 127. But out of 5,238 villages, all the deaths were returned from 1,954. Bowel complaints may be expected to become less fatal as sanitary work advances, but we would suggest whether some special inquiry might not be carried out in Akola district, for it is just possible that local reasons may exist for part of this great rate (8·3 per 1,000) there. As regards the towns, the question may be asked why, for instance, Akot town should have a bowel complaint death-rate of 9·1 per 1,000, and Akola town, in the same district, a rate of 1·2 per 1,000.

25. *Injuries.*—Deaths from various classes of injuries were as follow:—

Suicides	152
Wounding, &c.	639
Snake-bite and wild beasts	212
Total	1,003 = ·4 per 1,000.

The mean annual deaths under the head of "Snake-bite and wild beasts" amounted to 243, a little over the number of 1882.

26. *Other causes* yielded 19,383 deaths, or 7·4 per 1,000 of the population, so that the causes of 25 per cent. of the total year's deaths are unknown.

27. *Sanitary Works (Civil).*—The total expenditure under the head of sanitary improvements in Berar in 1882 was as follows:—

	Civil Stations.	Municipal Towns.	Non-Municipal Towns.	Villages.	Total.
	£	£	£	£	£
Conservancy	266	2,975	1,792	544	5,577
Drainage	320	800	377	896	2,393
Water-supply	188	435	349	2,154	3,126
Other sanitary improvements	832	1,001	841	472	3,146
Total 1882	1,606	5,211	3,359	4,066	14,242

The sum spent on sanitary work is not large, but it shows a certain appreciation of the necessities of the case. As we have often said, however, the main village improvements, except, perhaps, providing new water-sources, can all be done by the people themselves. Outlay has been incurred for current sanitary work rather than for new works, but, nevertheless, some advance appears to have been made in providing new works.

28. The town of *Khamgaon* is providing a water-supply of 20 gallons per head per day for a population of 12,400. No account of the work is given, but it will cost about 17,000*l.*

29. *Amraoti* is to receive a water-supply of 20 gallons per head per day for a population of 25,000. It is to be supplied from a tank and drainage area of 3·3 square miles. The estimated outlay is 27,886*l.* The water will be distributed by pipes into the town, but the method of partial delivery by dipping wells should be avoided altogether. It is intended to put up hydrants 500 feet apart, and with such a water-supply there ought to be the necessary means of distributing the water in a pure state, either by hydrants or by cisterns above ground, with suitable taps. Dipping wells are simply a modification of the ordinary Indian well, and water in them is subject to all the usual sources of surface impurity and foul drawing vessels and ropes.

In Amraoti municipal town surface drains have been extended, conservancy arrangements have been improved. "The waterworks now in progress will be a great boon to this town."

30. *Ellichpur.*—"No regular system of drainage. Rain-water is carried off by side cuttings, and waste water from the houses runs into cesspits, which are emptied periodically." It is not unlikely that part of the great death-rate of this town may be due to polluted subsoil. Its death-rate in 1882 was 26·5 per 1,000, and its previous five years' average rate was 40·1 per 1,000.

31. *Akola.*—Surface drains, to the extent of 6,090 feet, have been provided, and "the town has been surveyed with the view of systematically carrying the drainage scheme to completion." Water-supply is abundant, and the conservancy has been improved.

32. *Khamgaon.*—The new town drains "are open masonry surface drains, and carry off all sullage water from the houses, which before used to stagnate in cesspits and sink into the soil." The new water-supply will afford ample water for everything, but care should be taken that all refuse water is removed at once from the town site. Conservancy well carried out.

33. *Shegaon.*—This small town had been under the Municipal Act for a year. But the funds were limited. Some drains were repaired, dust bins were erected, and a few latrines provided.

34. It can scarcely be said that the works in municipal towns have been on an extensive scale during the year; and that great need exists for more activity in this important matter is shown by the death-rates of 11 towns in the returns, which amounted in the aggregate average to 29·7 per 1,000 against 35·7 per 1,000 on the average of five previous years. The rates in five of these towns exceeded 4 per cent., and all except one were above 25 per 1,000 on an average of the previous five years.

35. *General Remarks.*—Under this head are included inspection reports drawn up by the Sanitary Commissioner. They contain a considerable amount of useful information of local interest, and as some of the statements involve general principles, we shall extract them as illustrating the nature of epidemic disease causes in India as well as in Berar. Take, for example, the town of Akola, with a population of 16,614, and a five years' average death-rate of 46 per 1,000. For draining this town deep surface masonry drains were being provided, difficult to keep clean. Shallow saucer-sectioned drains were proposed, but objected to by the executive engineer on the ground that there was not sufficient water to flush them, and he proposed underground drains instead. All house sullage was to run into the shallow surface drains, and so into shallow sectioned main drains to the river.

36. The question raised in the discussion is simply whether cesspits should be continued and kept out of sight, or whether cesspool matter should be passed into surface drains with deficient water for flushing. Clearly the real question is that of water-supply. With the concentrated flow of closed pipe drains much less water suffices for cleansing than is required for shallow surface drains; but in either case there must be sufficient water, and then the question arises as to the comparative sanitary advantages of each class of drains. We have stated the points which require consideration in our suggestions for the sanitary improvement of Indian stations, and it may be stated generally that the safest way to dispose of household excreta in cases where closed drains

are not adopted, is to make provision in the sanitary administration for collecting and removing daily all household sewage, and in this case the ordinary refuse water of households might be passed into properly laid impervious surface drains to keep it out of the subsoil, and to pass it by the aid of water to an outfall. In some Indian towns water for this purpose is raised specially from wells. Water for the purpose at Akola might possibly be obtained from the river. It will be seen that in no case is it advised that cesspool matter from a town or large village population should be passed into open surface drains in the public highways. The advantage of a closed system of drains with sufficient water is, that it solves all the difficulties, especially if the sewage be applied for agricultural purposes.

The present report shows conclusively that until some such system of drainage combined with water-supply is adopted for Akola, there must be great improvements in the conservancy. All cesspits and privy wells should be filled up forthwith, and cesspool matter collected and removed for application as manure by hand.

37. A very unsatisfactory account is given of the civil station of Akola. The house compounds are made the places of deposit of sewage. "There are no latrines, and no arrangements made for the removal of house refuse." I noticed, says the Sanitary Commissioner, "some heaps of stable "sweepings thrown on the side of the public road. The native servants resort to pits just in "front of these quarters, and empty the house night-soil into them also. These pits were caused "by digging unorum for the roads." All these unwholesome practices ought to cease under a proper conservancy system; but, he continues, the municipal authorities "want experience and guidance." So far as can be judged of from other reports, this want is a general one, and ought, as far as possible, to be supplied by the Sanitary Commissioner and his assistants.

38. Local civil authorities can lend efficient aid in sanitary work, as in the instance of Khamgaon town, where "Mr. Dunlop has been indefatigable in his endeavours to improve this town, and it must be a source of much satisfaction to him to see his efforts so far crowned with success." But in this instance, as in Akola, the house drainage system appears to constitute the chief difficulty. The present position of this matter is as follows:—"House moris, or cesspits, which were the great "sanitary defect in this town, are being done away with, and the house sullage, instead of running "into pervious cesspools, thus causing corruption of the soil, and creating numerous foci of disease, "is now being run into these open saucer drains, and carried outside the town. The great "advantage of open saucer drains is that it can be seen at a glance whether they are clean or not, "and whether the sweepers are doing their duty. Closed drains get clogged with filth and refuse, "and being out of sight are also very often out of mind until they become utter abominations, "poisoning the air with noxious gases." Both of these positions may be sustained as correct. As we have stated in the case of Akola, all depends on the water supply, and also on good primary execution and subsequent oversight. Latrine matter is removed by hand labour, but urine is permitted to mingle with other refuse water, and is passed into the street drains, the reason being not that it is considered the best arrangement, but because the municipality do not wish to undertake the separation on the score of extra expense.

39. The question of adopting the best method of house drainage is also closely connected with the number of inhabitants. The population of Akola is 16,614, and of Khamgaon 12,390, and in either case considerable latitude might be allowed in deciding on the drainage system. But the case is otherwise with large cities, where, on the score of economy, an efficient system of house water-supply with proper house drainage would be more economical than the large and constant expense which would have to be incurred for an equally efficient method of hand cleansing.

40. In the course of the year a number of villages were inspected with this practical result, that the great remedy against epidemics in all of them is cleansing, keeping clean, and the provision of pure water. Their condition is described as follows:—

"A great defect in the conservancy arrangements of these villages is the number of dung-heaps "found either inside or at every few paces all round the outskirts. These dung-heaps, when "saturated by rain, ferment and decompose, and the resulting foul exhalations from them pollute "the air circulating through the village, and thus generate disease. In addition to polluting the "air, these dung-heaps also foul the water of the wells, for in the rains the surface drainage "dissolves much of the deleterious salts contained in the manure which, along with the lighter "particles of the heaps, find their way into the wells." Much of this universal prevalence of filth is due to the practice of stalling cattle inside villages, or even inside houses. In one village of about 2,000 inhabitants 2,000 cattle are stalled.

These village facts are quite sufficient to account for all the epidemic severity with which the rural districts of Berar are visited, and they also clearly indicate the sanitary measures required for protecting the lives of the people. Rules for their application have been circulated; but, so far as the information goes, they have been only feebly responded to. Local disease causes, whether in towns or villages, have been generally investigated; but, in view of the very great diversity in epidemic death-rates in different towns and districts, some technical local inquiries, including local drainage defects, appear to be required. But, above all things, more activity in turning to account the knowledge we at present possess is the remedy required, and this is our general conclusion from Dr. Little's latest and last contribution to the practical sanitary history of these provinces.

7th April 1884.

No. 9.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for Assam for 1882.

1. The year 1882 was marked by an important extension of registration in Assam. This was part of an improved system, which, however, did not come into full operation until the 1st July, and consequently the data are only available for the last six months of 1882, during which the registration of births was effected for the first time in two plain districts, Sylhet and Cachar, which previously only returned deaths, while returns both of births and deaths were made for two hill districts, Khasi and Jaintia hills and Garo hills, for the first time. In subsequent years, therefore, we may expect registration returns for the whole of Assam except for the population of Naga hills, which does not at present admit of being brought under any general system of record.

2. The population from which returns both of births and deaths were obtained for the completed year 1882 was 2,225,271. The population from which death returns only were received for the whole year and birth returns for the latter half of it was 2,258,434, and the population which made returns of births and deaths only for the last six months of 1882 was 44,229.

The birth registration in the last group was carried out only in selected areas. We may, however, expect that in future years births and deaths will be registered among 4,527,934 people, or virtually for the whole population. A beginning of this important work had been made, and it is satisfactory to learn that no insurmountable difficulties have been encountered in it, and that our recommendation for introducing registration into tea-gardens had been carried out.

3. The results of birth and death registration for 1882, taken on the census population of 1881, stood as follows:—

Population returning Births for the whole year 1882.	Birth-rate per 1,000 of Population.
2,225,271	26·34

Population returning Deaths for the whole year 1882.	Death-rate per 1,000 of Population.
4,483,705	25·85

It is clear that the registration of births is defective, and no explanation short of this would account for the facts; but it is at the same time satisfactory to see how much really good registration work had been done in the course of the year.

4. The following abstract gives the census population and area for each district, together with the birth and death registration results for 1882:—

Districts.	Population, 1881.	Area in Square Miles.	Births per 1,000.		Deaths per 1,000.	
			1882.	Last Six Months 1882.	1882.	Last Six Months 1882.
Goalpara	446,282	3,897	32·69	—	32·94	—
Kamrup	644,960	3,631	27·65	—	32·88	—
Nowgong	310,579	3,417	22·97	—	26·14	—
Darrang	273,333	3,418	22·34	—	29·03	—
Sibsagar	370,274	2,855	27·48	—	23·95	—
Lakhimpur	179,893	3,723	15·44	—	14·74	—
Sylhet	1,969,009	5,440	—	11·19	23·59	—
Cachar	289,425	1,285	—	14·	20·66	—
Khasi and Jaintia Hills	43,485	—	—	17·98	—	16·14
Garo Hills	744	—	—	32·25	—	—

This abstract shows precisely the state of the registration at the commencement of the new decennial census period. The six months' columns will disappear in 1883, and thenceforth the whole province will make returns annually, but the registration in hill districts will, in the meantime, only represent the ratios of births and deaths in selected areas. As the figures stand, they show deficiency to a considerable extent in the birth registration in certain districts, but otherwise good registration work.

5. *Births.*—The first six districts in the table for which a year's birth-rates are given had a census population in 1882 of 2,225,271, and births stood as follow:—

Males	30,194
Females	28,432
Total	58,626

The remaining population was 2,302,663, and from among these there were the following births recorded during the last six months of 1882 :—

Males	13,697
Females	13,212
Total	26,909

The birth-rate for the first series was 26·34 per 1,000 for the year, and for the second series 11·68 per 1,000 for the last six months of 1882.

6. *Deaths.*—The preceding table shows that deaths were returned for a whole year for eight districts with a population of 4,483,705, and for one district for six months. The year's deaths in the eight districts were as follow :—

Males	61,678
Females	54,242
Total	115,920

The six months' deaths returned from the Khasi and Jaintia hills were, of—

Males	373
Females	329
Total	702

The year's death-rate for the first group was 25·85 per 1,000, and the six months' rate for the hill district was 16·14 per 1,000.

The ratios of births and deaths, according to sex, and for the districts where a year's data are available, were as follow :—

Males born per 100 females	106·19
„ died „	113·70

Similar ratios of births and deaths have been registered all over India, and if correct, would show a gradual decrease of males. They are, however, the result of incomplete registration. A similar circumstance may probably account for about 41½ per cent. of the deaths being returned at and under five years of age.

7. The next abstract gives briefly, the vital statistics of different classes in Assam :—

Classes.	Population.	Death-rates per 1,000 in 1882.
Mahomedans	1,812,220	23·89
Hindus	2,626,383	22·27
Christians	4,289	22·85
Other classes	138,813	129·56
Total	4,483,705	25·85

8. There are nine towns in the eight districts with a conjoint population of 62,211. Their death-rate in 1882 was 29·48 per 1,000. The district death-rate, apart from that of the towns, was 25·80 per 1,000 against a five years' mean of 11·30 per 1,000, affording another proof that registration is improving and that a more correct estimate of the sanitary state of the population is gradually being arrived at. This conclusion is further sustained by the following registered deaths for the last three years :—

1880	51,666
1881	71,941
1882	115,920

We shall next discuss the causes of these deaths.

9. *Causes of death.*—The following were the classified death causes in 1882 :—

	Deaths.
Cholera	21,055
Small-pox	3,195
Fevers	60,218
Bowel complaints	14,074
Injuries	1,150
All other causes	16,228
Total registered deaths	115,920

10. *Cholera.*—There can be little doubt that the deaths in this abstract ascribed to cholera are approximately correct. In the two preceding years the deaths under the same head were 2,803 and 5,010 respectively. It is not improbable, however, that many deaths from cholera escaped registration in these years; any way, the cholera death-rate of 1882, which was 4·69 per 1,000, was very high, and it was apparently related to the great epidemic of cholera which existed over the whole area of Bengal in the same year. In one district, Kamrup, with a population of 644,960, above a third of the whole cholera mortality of the year took place. In this district 7,896 people died of cholera, equal to a ratio of 12·24 per 1,000. Deaths from cholera were registered in all the districts of Assam and in all the nine towns. The death ratio in the districts was 4·69, and in the towns 5·33 per 1,000. The epidemic attacked 3,082 villages out of 18,701, and deaths from it were returned from 314 out of 686 circles of registration, thereby affording a striking confirmation of a law of cholera diffusion to which we long ago called attention, namely, that the intensity of an epidemic is represented not only by the number of deaths in each locality, but by the number of localities attacked.

Even in Kamrup district, which suffered so severely that the cholera deaths averaged 10 per attacked village, 777 villages were attacked, and 1,785 escaped the disease. The epidemic in Kamrup district was made up of 777 endemic seizures in separate localities. If, on the other hand, we take the case of Goalpara district, with a population of 436,642, which had a cholera death-rate of ·91 per 1,000, and Lakhimpur, whose population of 172,740 yielded a cholera death-rate of ·53 per 1,000, we find that, although 13 out of 23 circles of registration in Goalpara district returned deaths, only 54 villages out of 1,225 suffered. These 54 villages yielded 406 deaths from cholera, or about 8 deaths per attacked village on an average. In the same way in Lakhimpur district cholera deaths were returned from 9 registration circles out of 108, and from 14 villages out of 1,100. There were in all 96 deaths from cholera, averaging about 7 per attacked village.

11. The next abstract shows the deaths from cholera registered month by month for the province:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January - - -	1,017	July - - -	1,611
February - -	869	August - - -	608
March - - -	1,701	September - -	384
April - - -	1,916	October - - -	863
May - - -	4,952	November - -	1,757
June - - -	3,583	December - -	2,694

This table shows the overlapping of two epidemics, one in the Bramahputra valley, which culminated in April, May, June, and July, the other in the Surma valley towards the end of the year, and probably passing over into next year. No general comparison can be made between the total cholera mortality and rainfall for this reason; but the Sanitary Commissioner has made a useful addition to cholera history in 1882, by placing the rainfall of head-quarter towns alongside the cholera deaths in the same districts, and from his tables the following results have been tabulated:—

Months.	Kamrup.		Nowgong.		Sibsagar.		Sylhet.		Cachar.	
	Cholera Deaths.	Rain.	Cholera Deaths.	Rain.	Cholera Deaths.	Rain.	Cholera Deaths.	Rain.	Cholera Deaths.	Rain.
		Ins.		Ins.		Ins.		Ins.		Ins.
January - - -	588	0·03	8	·48	2	1·63	356	—	50	·29
February - - -	333	1·29	9	1·65	1	2·82	460	2·84	59	3·78
March - - - -	709	4·69	87	4·85	—	5·19	751	13·77	111	14·05
April - - -	968	2·39	198	3·51	3	8·98	574	18·82	61	6·97
May - - -	2,745	7·91	447	11·85	29	4·02	272	23·85	177	18·93
June - - -	1,790	8·79	796	11·26	130	9·29	456	27·76	134	24·68
July - - - -	505	7·58	536	5·96	161	10·26	112	12·60	75	9·28
August - - -	102	15·00	173	13·55	33	15·13	151	44·92	31	17·79
September - - -	62	2·45	8	5·15	14	12·08	180	17·68	63	7·22
October - - - -	47	13·26	1	12·04	12	10·33	719	14·81	72	5·62
November - - -	17	1·36	—	0·48	96	1·29	1,421	·10	207	·75
December - - -	35	—	12	0·29	273	·67	2,010	—	302	·04
Death-rate per 1,000 of population - - -	12·24	—	7·22	—	2·03	—	3·75	—	4·63	—
Rainfall - - - -	—	66·75	—	71·07	—	82·19	—	176·65	—	109·40

These five separate sets of observations show that the lowest cholera death-rates co-existed with the higher rainfalls of the year, and that the lower rainfalls had the higher death-rates. Taken by months, it may be concluded generally that increasing and cumulative rainfall was accompanied and followed by decline of cholera, and there is also an indication of rise in cholera death-rates with reduction of rain.

As the monthly temperatures and temperature ranges are not given, we have no means of estimating their relation to cholera mortality.

12. Some interesting information on topographical and local accompaniments of the epidemic are given, from which the following facts are abstracted:—

Barpeta thana, in Kamrup district, had a cholera death-rate of 23·60 per 1,000, in reference to which the medical officer remarks:—"Its natural features stamp it as a typically pestilence-stricken "region. Much of the land is periodically inundated; every rise in the level of the Brahmaputra "puts it under water. The subdivisional town, Barpeta, is a miniature mud Venice, its streets "during half the year being waterways for boats, by which communications are carried on. It is "densely populated, and in many parts highly cultivated."

Gauhati town was visited by a slight epidemic, which began by a single death in January, and another in February. It culminated in 38 deaths in May, and ended in three deaths in July. The medical officer states of this attack that "it seemed to miss the most insanitary and worse regions "of the station, and the poorer and most ill-provided of the inhabitants, while it entered the best "houses occupying the best sites, and struck down those persons surrounded apparently by the best "sanitary precautions the town is yet capable of.

"The regions chiefly attacked lay near the river, and their most accessible source of water supply "was the river, than which the town has no better, . . . I do not think that in this short "outbreak the water-supply entered as a factor." And there being thus no evident cause for the outbreak, he says: "The disease was imported and travelled along lines of communication chiefly in direction of the wind."

If sanitary conditions afforded no help towards accounting for this outbreak, neither will the contagion and importation theory. The imported case was taken ill and died on the 30th April:—"He sickened and died on the 30th of April." But cholera existed during the three preceding months in Gauhati as well as in Gauhati thana, and of the first supposed "infected" case, it is stated that "on the 29th a man living near by was seized and died," that is before the importing case was taken ill. There is thus no foundation for the supposed importation, neither is such an agency necessary to elucidate the facts, which were as follow:—

Kamrup district was the seat of a severe epidemic outbreak which was part of the year's cholera, and 7,986 people died in this district, of whom 57 died in Gauhati town, and 304 in the thana. Cholera was most severe along the river, a well-known aggravating locality. The sanitary account given of attacked places refers not to absolute sanitary condition at all, but to relative sanitary condition. It is quite possible for the more elevated positions to suffer and the low ones to escape. This is matter of knowledge, and extends to the behaviour of cholera for hundreds or even thousands of feet of elevation. What really is wanted in such apparently anomalous cases as the present is to examine and report minutely on the absolute sanitary condition of affected houses and districts, with the view of improving them. We have devoted more space to this discussion than it merits, because it belongs to a class which has done great injury to sanitary work in India as elsewhere, and the practical result is that such statements should never appear in sanitary reports intended for practical purposes. The remark of the Sanitary Commissioner that "it appears quite clear that the conditions "necessary for the development of the disease existed in the Pan Bazaar, it was the breeding ground "of the contagium, from thence it spread," affords no clue to the history. It should be shown that "contagium" exists, and what it is, and, moreover, that it can spread the disease and how it does it.

For practical purposes we cannot do with less than this. On the other hand, we know from experimental inquiry that cholera cannot be communicated to any of the lower animals, not even to monkeys, and there is no satisfactory proof of its having been communicated to human beings. Inferences in such questions are next door to errors, and in the present state, at least, of the inquiry into cholera, it is safer, so far as the interests of the public health are concerned, to leave them out of official reports.

In regard to cholera in *Sylhet*, Dr. Macnamara, the civil surgeon, says that it is never wholly absent from the district. "It is endemic and propagated locally, but it is also epidemic, and its "course can sometimes be traced. It is true no importation theory will account for it in all cases. "The difficulty I find is, while accepting the theories of its propagation as generally laid down, to "explain why it ever stops under all the insanitary conditions under which we suffer. I believe the "general wave of cholera in the district during the year took a south-westerly direction, following "the course of our two great rivers, and rarely going far from them except in cases where a con-"nexion could be traced" (cases not given). "It is easily understood why this should be so, as the "river banks are used as public latrines, and for the reception of half-burnt bodies." With reference to the opinion stated in this passage, that cholera spread in a south-westerly direction, it is not borne out by the statistics of which an abstract is given in paragraph 21. This table shows that cholera existed in all the districts in January, and that in all the months Kamrup, which is the most westerly district except Goalpara, suffered most. Cholera, indeed, shaded away from Kamrup to the north-west. Dr. Macnamara's observations point to the existence of cholera independent of conditions, as well as to the determining influence of local causes. This latter fact is more clearly stated by the civil surgeon in his report on Sylhet municipality, which he describes as "an area thrown, by the "perversity of its inhabitants, ignorant of the simplest principles of sanitation, into a number of "elevations and depressions, the former covered with decaying vegetation, and the latter filled with "decomposing sewage, while the whole is buried in an atmosphere so noisome as to be at times very "offensive to the sense of smell." To this the Deputy Commissioner replies:—"While horribly "insanitary, it has proved generally healthy, though in 1882 cholera has swollen our death-rate. "The insanitary condition of the town is admitted." Here we have the statement made that insanitary condition and health can exist together. This is, however, a mistake, for on turning to the statistics we find the death-rate of Sylhet town to have been 33·80 per 1,000, including 6·73 from

cholera, while for the previous five years the death-rate averaged 35·95 per 1,000, an enormous rate for a small population of 14,407. The Sanitary Commissioner himself adds the remark that on his late tour of inspection he "failed to find any sanitary improvement in this municipality during the year." The practical conclusion is obvious enough, namely, that steps should be taken to make the municipality discharge its duty.

The following extraordinary statement about cholera in Cachar district is made by the civil surgeon. There were 1,342 cholera deaths, equal to 4·63 per 1,000 of the population, and 172 villages out of 450 were attacked. The civil surgeon states that he "inspected several villages himself, and could "find out nothing definitely. At a place called Natwanpur there were 17 deaths. The outbreak "was traced to two Manipuris bringing cloth from Lakhipur, where cholera had prevailed, and "selling it to the coolies." No attempt whatever is made to justify this opinion as to importation, while every report has shown year after year that Assam villages are in the very worst sanitary condition, and the very spots where cholera would be likely to appear during an epidemic.

The Deputy Commissioner states that "the insanitary condition of the villages remains much the same," although some efforts have been made towards improving them. It is in this direction that means are to be found for mitigating the ravages of cholera, and not in quarantine for stopping the importation of cloth. We need scarcely say that the unsupported opinions about cholera contagion enunciated in India are gladly accepted by quarantinists in Europe as affording justification for their own equally unsupported opinions. The only suggestions that appear applicable to such cases is that all similarly unsupported theoretical notions should be struck out of civil surgeons' reports before any notice is taken of them.

13. *Small-pox.*—The following have been the death-rates from small-pox during the last three years:—

Years.	Small-pox Deaths.	Ratio per 1,000 of Population.
1880	2,239	·59
1881	3,129	·69
1882	3,195	·71

The next abstract shows the monthly small-pox deaths, and it includes, besides the number for 1882 already given, 2 deaths in Khasi and Jaintia hills district, 3,197 in all.

Months.	Small-pox deaths.	Months.	Small-pox deaths.
January	216	July	243
February	201	August	173
March	419	September	95
April	567	October	87
May	566	November	108
June	365	December	157

Small-pox was generally diffused over the province in 1882. All the districts returned deaths from it, but its attacks were local, and deaths were registered from 246 circles out of 686, and from 1,368 villages only out of 18,701. As usually happens in India, the hot months yielded most of the deaths.

No vaccination statistics are given, but there appears to have been a considerable increase of operations during the year.

The death-rate from small-pox in the towns slightly exceeded the country rate. It was ·85 per 1,000 for the former against ·71 for the latter.

14. *Fevers.*—As usually happens, the chief death cause of the year was registered under this head. Fever deaths were returned from all the districts, from 484 out of 686 circles of registration, and from 11,262 villages out of 18,701. The fever deaths were 60,218, distributed month by month as follows:—

Months.	Fever deaths.	Months.	Fever deaths.
January	4,973	July	5,758
February	3,919	August	4,780
March	3,922	September	4,998
April	4,317	October	5,452
May	4,927	November	5,793
June	5,219	December	5,160

Besides these monthly fever deaths there were 212 returned from Khasi and Jaintia and Garo hills, the total year's fever deaths were hence 60,430.

15. In a previous table we have given the statistics of cholera in relation to rainfall, and it may be useful to reproduce the climatic data to show their relation to fever mortality.

Months.	Kamrup.		Nowgong.		Sibsagar.		Sylhet.		Cachar.	
	Fever Deaths.	Rain.	Fever Deaths.	Rain.	Fever Deaths.	Rain.	Fever Deaths.	Rain.	Fever Deaths.	Rain.
		Ins.		Ins.		Ins.		Ins.		Ins.
January	927	0·03	321	0·48	271	1·63	1,862	—	176	·29
February	733	1·29	265	1·65	232	2·82	1,382	2·84	111	3·78
March	733	6·69	286	4·85	228	5·19	1,168	13·77	120	14·05
April	755	2·39	286	3·54	238	8·98	1,439	18·82	145	6·97
May	1,031	7·91	341	11·85	297	4·02	1,435	23·35	186	18·93
June	981	8·79	346	11·26	349	9·29	1,714	27·76	160	24·68
July	1,000	7·58	355	5·96	517	10·26	1,914	12·60	314	9·28
August	744	15·00	306	13·55	502	15·13	1,580	44·92	298	17·79
September	678	3·45	274	5·45	549	12·08	1,798	17·68	194	7·22
October	834	13·26	319	12·04	566	10·83	2,125	14·81	236	5·66
November	845	1·36	348	0·48	476	1·29	2,332	·10	240	·75
December	868	—	281	0·29	447	0·67	2,615	—	305	·04
Death-rate per 1,000 of population	15·70	—	11·98	—	12·61	—	10·35	—	8·58	—
Rainfall	—	66·75	—	71·07	—	82·19	—	176·65	—	109·40

This abstract shows a relation between rainfall and fever mortality to which topographical conditions appear to contribute. Assam fever mortality has never been so high as the fever death-rate returned from other provinces of India. The rate in 1882, namely, 13·43 per 1,000, was much higher than the previous five years' average, which was 6·09 per 1,000. It will be observed that the two districts, Sylhet and Cachar, which are among the wettest in India, returned the lowest fever death-rates. Water by itself does not raise fever death-rates, for these flooded districts were less affected by fever than Assam districts where the lowest rainfall took place.

We know from experience elsewhere, especially in the North-West Provinces, that in the existing state of irrigation and drainage works there, such rainfalls as those of Sylhet and Cachar would have led to the population being decimated by fever. Hence the state of the subsoil must have some relation to fever mortality. Simple flooding rather tends to lower epidemic death-rates, and in Assam and adjoining districts in Lower Bengal we know that when the surface of the country is under water cholera is as effectually extinguished as a fire would be.

Malaria is the product of heat, moisture, and vegetable decomposition, and in a country where it shows itself by its effects on public health, its extent can be reduced by lowering the water level and increasing subsoil water movement, and, here in Assam, a similar result follows from raising the water level until the surface is covered. Probably there is more movement of subsoil water in Sylhet and Cachar than in other fever-stricken regions, and then we have the fact shown in the preceding table that in both districts the fever mortality rises when rainfall is reduced and evaporation with temperature variability succeeds. Of course the influence of purely local causes in villages, such as damp subsoil, bad houses, filth, bad water, and excessive growth of jungle, must not be overlooked; but it is unlikely that there is such a difference in these elements in Sylhet and Cachar as to account for the lower fever death-rates; hence we must admit that under topographical and general climatic conditions in these districts excessive rainfall is beneficial to health, and the most probable reason of this circumstance is that there is better subsoil drainage and consequent cleansing of the subsoil and replenishing of water sources brought about by the heavy rainfall.

The practical result of this discussion, therefore, is that as we cannot lessen the rainfall, the best course to take is to improve drainage outlets where this can be done, and to improve the local drainage and other sanitary conditions of villages.

16. Before concluding our remarks of Assam fevers, we may notice briefly "a form of malarial "poisoning known among the natives as *kálá ázár*, or black sickness, from the darkened colour "which the skin assumes in chronic cases." The medical officer at Tura states "that it begins with "a high temperature, severe pains in the head and body, loss of appetite, and other symptoms of "general febrile conditions; fever sometimes of an aguish form, and sometimes fever without "remission for many days together. The spleen and the liver enlarge, the skin becomes gradually "darkened, and in advanced cases there often is hæmorrhage from the nose and gums, œdema of "the feet or general dropsy, is likewise common, and life ends by a combination of disordered "functions known as malarial cachexy." The Sanitary Commissioner does not consider this to be a new disease. The cases take place in the Garo hills, and have been known as they now appear for the last 20 years. He further says that "the localities chiefly in which the disease prevails "are those which combine all the conditions under which the most intense forms of malarial diseases "are produced. . . . . It is so inimical to life that large tracts of hill country are being "depopulated in consequence. The affected localities are those where the low densely-wooded Garo "hills join on to the low-lying central Assam plain. It extends also to some distance into the hill "country, where the lower outer ranges are overtopped by higher interior ranges, but among these "higher hills the disease is almost unknown. The villages where it is prevalent are often built in "the midst of dense jungle, which the sun cannot penetrate and where the air cannot have "access."

The disease is yet imperfectly known on account of local prejudices of the people, but so far as an opinion can be formed about it, this Garo fever is only an intense form of Terai fever taking place among people living under aggravated topographical and local Terai influences.

The remedies proposed by the Sanitary Commissioner are clearing, drainage, and other similar improvements, but he very properly points out that the partial annual clearings by the people living on the spot are a probable added cause of sickness.

In cases such as this, the best remedy would apparently be to treat the affected tracts as new country, to remove the people to the high ground until the country is cleared and cultivated. But the question suggests itself, whether the enforced depopulation of such an unpromising tract does not point to the best and cheapest remedy, namely, the emigration of the inhabitants?

17. In our memorandum on the Assam Report for 1880 we noticed six cases of enteric fever as having occurred among Khasias living in a very filthy village, Maokar, which had, nevertheless, been supplied wholly or partially with pure water; and, as the case appeared to be one in which the prevalent water etiology might be put to a test, we asked this pointed question, "Did the cases take place before or after the better water was introduced?" To this the Sanitary Commissioner replies as follows:—"Enteric fever among the people of Maokar occurred between the months of July and "November, *after* the introduction of the new water-supply into the suburbs or outskirts of the "village." But at that time the village itself does not appear to have had good water.

18. *Bowel complaints.*—Diseases registered under this head are returned from a larger comparative area in Assam than in any other province. In 1882 bowel complaint deaths were registered in 451 out of 686 circles, and out of 18,701 villages 5,172 returned bowel complaint deaths.

The monthly mortality from them was as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	1,001	July	1,297
February	745	August	1,211
March	758	September	1,230
April	1,604	October	1,348
May	2,134	November	1,275
June	1,866	December	1,565

The total bowel complaint deaths of the year amounted to 14,074, or 3.13 per 1,000 of the population. The previous five years' rate had been 1·60 per 1,000, but this does not show more deaths under the heading in 1882, only much better registration. No account is given of the local causes of bowel complaints (chiefly diarrhœa and dysentery); but it may be fairly assumed that these are of the same general nature as prevail in all towns and villages.

19. *Injuries.*—Among deaths from injuries there were registered—

85 suicides.
797 wounds and accidents.
268 from snake-bite and wild beasts.

1,150 = ·26 per 1,000 of the population.

20. *Sanitary Works (Civil).*—Under this head are given returns of expenditure from 13 towns, municipalities, &c. The total amount was 5,656*l.*, and its objects were as follow, in round numbers:—

	£
Medical relief	297
Vaccination	46
Drainage	886
Water-supply	208
Conservancy	1,520
Disposal of dead	13
Roads and culverts	2,294
Markets and slaughterhouses	217
Village sites	22
All other sanitary improvements	152

Most of the year's expenditure, as will be seen, was laid out on useful sanitary work.

There are a few points in the municipal reports which are worthy of record. The *town* of *Shillong*, besides attending to conservancy and drainage, has had a constant water-supply introduced, which is derived "from the steep, grassy, uninhabited hill slopes above the Crinoline falls. Culti- "vation is prohibited on the watershed, and the whole area is strictly preserved by the Forest "Department." After discussion, it was decided by the municipality to adopt subsidiary reservoirs, "into which the pure filtered water would be flowing night and day," from which it was to be laid on at high pressure to the extent of 20 gallons per head per day. "Pipes were ordered from "England, and the head works, reservoirs, and filter beds constructed, and by June 1883 the water "will be laid on to the various houses in the civil station and to the bazaar." The cost was estimated at Rs. 12,984. An attempt was made unsuccessfully to raise this amount by loan, and the work was carried on by advances made by the local administration. The population of the

town of Shillong is given in the statistics at 3,606; so that if all the people are to benefit by this work the capital outlay will be about 7*s.* per head.

As a proof of the coldness of the climate in winter, it is stated that a water-pipe was burst by the frost in January.

The town of *Gauhati* will, it is hoped, be soon provided with a similar water-supply. The following scheme had been adopted by the Commissioners and commenced:—"The water is to be procured "from the Brahmaputra by sinking a well in the south bank of the river, and from it to be pumped "into a reservoir on a small hill, which will afford a head of about 70 feet above the town. Settling "and filter tanks are to be provided, and a service reservoir, namely, a deep circular tank with "concrete floor and brickwork sides, covered by a roof to exclude heat. . . . . The delivery "will be by the means of about 20 closed tanks furnished with draw-taps and by stand-pipes. "Private houses and Government buildings are to have their own supply pipes and taps." The daily supply will at first be 100,000 gallons, but this can be doubled without adding to the works. The estimated cost is Rs. 38,214. The population of the town was 11,695 in 1881, so that the capital outlay will be a little over 6*s.* 6*d.* per head. It would be a great advantage if we, at home, could have our water-supplies provided at such a rate. The advantages of pure water-supply are, however, not confined to the plain towns. Far away up in the Naga hills, at an elevation of 5,500 feet, is Kolima, where a native infantry regiment is now stationed, with a cantonment and civil station. Water is obtained from a mountain stream as a source. "Already settling tanks and filter beds have "been constructed, and a considerable quantity of iron piping brought up. From the filter beds "a main two-inch pipe will run into an iron cistern in the fort. From the cistern two branch pipes "will carry water, one to the civil lines, and one to the cantonment. On the branches will be "placed overflow cisterns at intervals, and these will furnish the water-supply to the whole "population," which is about 3,000, and the supply will be at the rate of six gallons per head. At several stations and towns sanitary work is being done, but nowhere on any large scale, and little progress has as yet been made in improving villages. It may be suggested that wherever water is conducted from a distance into any locality, provision should be made for draining it away again after use, otherwise increase of fever may follow its introduction.

21. *General Remarks.*—The most important part of these remarks applies to the question of coolie transport up the Brahmaputra, and to outbreaks of cholera on board the steamboats. It may now be considered as a settled point that the view originally held as to cholera-tainted water having been the cause of cholera on the voyages was erroneous. Water-supply on board coolie steamers is of unexceptionable quality, and the causes must be sought for elsewhere. So far as can be judged of by the facts stated in the present Report, these are of the following kind. Cholera is always more or less prevalent in districts from whence coolies arrive at the ports of embarkation, so that predisposition to cholera may be already present among them. The steam transports themselves appear to be kept in good sanitary condition, but in the course of upward voyages they move slowly up stream through districts where on both banks of the Brahmaputra cholera prevails, and in these districts the disease has been known to show itself in comparatively good houses, proving the existence of the epidemic and its activity along the river banks. It must also be remembered that epidemic intensity is a potent factor in cholera history as well as local insanitary conditions; and, bearing this in mind, it is not difficult to understand why these coolies, in passing slowly through a cholera infected district, should have furnished a certain number of fatal cases.

The voyage from Dhubri, in Goalpara district, at the western extremity of Assam, to Dibrugarh, in Lakhimpur district, in the far north-east, may be assumed at from 360 to 400 miles, and usually takes from 12 to 14 days. No doubt many who enter on the voyage have come from localities where cholera always exists, and on this account may have been to a certain extent under cholera influence, but in 1882 it is certain that they entered and passed through districts where cholera prevailed epidemically.

This fact is shown by comparing the cholera prevalence in river-side districts with cholera deaths on board coolie transports for the same months as follows:—

Months.	Deaths from Cholera.								
	Goalpárá.	Kamrup.	Nowgong.	Darrang.	Sibsagar.	Lakhimpur.	Date of Embarkation at Dhubri.	Numbers embarked.	Deaths from Cholera.
January	17	583	8	—	2	1	12th	384	—
February	39	382	9	23	1	5	1st, 9th, 16th, 23rd.	1,517	8
March	5	709	87	27	—	1	3rd to 22nd	1,325	33
April	29	958	198	81	3	2	4th to 17th	1,107	7
May	81	2,745	417	330	29	1	5th, 22nd, 24th.	846	4
June	126	1,790	796	146	130	5	21st	43	1
July	40	505	536	151	161	31	—	—	—
August	21	102	178	90	33	7	—	—	—
September	4	62	8	49	14	4	—	—	—
October	2	47	1	8	12	11	20th	90	1
November	2	17	—	4	96	10	—	—	—
December	40	35	12	4	273	18	29th	342	8

The districts affected by cholera in this table are arranged from west to north-east, and coolies proceeding from Dhubri to Debrugarh would pass successively through them up the river. The evidence is not all that would be desirable for arriving at the causes of attacks on board the transports, but this abstract points forcibly to local epidemic prevalence as an efficient cause. Not only coolies but passengers suffered. The vessels were frequently inspected during the voyages, and reported in good sanitary condition. So far as removable causes of this nature are concerned, there appears to be nothing requiring notice. There is, however, one matter not referred to, in regard to which some information would be of importance. How does it happen that in a voyage of 12 or 14 days' duration the death-rates should be so enormously greater on board these inland emigration vessels than they are among coolies on outward emigration voyages to foreign countries? In 1882 there were embarked at Dhubri 12,636 coolies for transport upwards, and among these there died within the fortnight 79, giving a yearly average of 150 per 1,000. Leaving out cholera altogether the annual death-rate from other causes would have been 30·4 per 1,000.

The discussions which have taken place of late years have tended to clear away mistakes, and to bring us nearer to the truth about this river cholera; and we would beg to suggest, as matter for inquiry, whether emigrants on board these coolie transports are as well cared for in the matter of area, space, and shelter, especially at night, as they would be on board emigrant ships going beyond sea. This appears to be the next point to be looked to, and as there are months when cholera is least present in the country, as well as months when it exists in severity, we may repeat the recommendation we have made in our Memorandum on last year's Report, that these river voyages should be arranged as far as practicable so as to avoid the cholera months.

There is one matter bearing on the personal liability of these coolies which is of interest, viz., that the disease attached itself to groups of people coming originally from the same locality, so that if certain batches had not been embarked on a steamer there would have been little or no cholera on board it.

22. It will be seen that most of the present year's Sanitary Report on Assam is taken up with the disease history, and that, except as regards new water-supply, the Sanitary Commissioner has been able to report comparatively little work done.

The Government in its Resolution on the Report states, that "there is unfortunately not much to "record. . . . . The great needs of towns in Assam are a proper system of conservancy and "a good water-supply. The former is exceptionally difficult of attainment in this Province, because "no sweeper caste, accustomed to the work, exists, and mehters have to be imported from Upper "India at a heavy cost." Certain popular objections, and filthy habits also, stand in the way of local improvements, but we are bound to state that none of these circumstances are peculiar to Assam. Both the Government and its Sanitary Commissioner are perfectly aware of the improvements required for towns and villages, and all that we can do is to urge as strongly as we can, on the facts of the disease history, that some organized effort should be made to cope with epidemics by removing their local causes as far as practicable.

21st February 1884.

No. 10.

Memorandum of the Army Sanitary Commission on the Report on the Sanitary Administration of British Burma for 1882.

1. It appears to be necessary to commence our notice of this Report on British Burma by quoting the following paragraph (81) of the Report itself:—"This office" (that of the Sanitary Commissioner) "was in charge of Deputy Surgeon-General William Pearl up to the 31st March. Dr. Kelly "held office from the 1st April to the 3rd July, since which date the undersigned (D. Sinclair, M.B.) "has had officiating charge."

To any one who knows what sanitary work really implies and includes, such a state of the administrative arrangements for a Province amounts simply to an acknowledgment that there is no sanitary organization except in name, and that it would be better to discontinue the present half-and-half procedure, because we should then know exactly what we had to deal with.

The system, not the officers, must bear the blame, and the present year's Report shows that although some reporting has been done for a few towns, the sanitary problem for the great bulk of the population has not received, and in all probability could not have received, that amount of attention which its importance demands from officers charged with other onerous duties.

2. A paragraph following the one we have quoted contains the following statement (83):—"It "would be useless to further encumber this Report with those observations or my recommendations "in detail. The sanitary circumstances of most Burman towns, including the large municipalities, "are identical; and, generally speaking, the observations applicable to one were applicable to all. "There is ample room in all for greater cleanliness. Roadside drains are substitutes for sewers "and unoccupied sites for cover for latrines. In densely-peopled parts cesspits or small split "bamboo enclosures with no pit whatever are the usual destination of ordure. The ground beneath "the houses is polluted by rubbish, including, in many cases, human discharges. These spaces

" are frequently enclosed and converted into piggeries or fowl-houses. Scrub jungle and herbage " is not kept as low as it should. Wells are insufficiently protected from surface water, and near " enough cesspits to be dangerous from underground communication. To keep them passable " during the south-west monsoons roads are raised above the house sites, the road embankments " dam back the water, and the sites or parterres are, many of them, at this season of the year, two " or three feet under water. The contents of cesspits and wells are now freely interchangeable. " . . . . Village sanitation alone is applicable; one of the most effective aids to which is the " education of the people themselves."

3. We accept this general statement of the Burmese sanitary problem as being instructive and useful so far as it goes, but its practical result is to point to the need of dealing with the details on some definite and continuous system; and it is quite clear that, if the Sanitary Commissioner is to be the head of any such organization, he will be of very questionable utility, if he is to be changed every year, or three times in one year, as is shown to have been the case in the present Report.

In previous Memoranda we have urged that a better arrangement of the duties should be made, so that both interests, medical and sanitary, should receive their due share of attention, bearing always in mind that continuous local experience is necessary to the efficient application of sanitary measures, and the necessity for some rearrangement of duties is clearly shown in the present Report.

With these remarks on the sanitary administrative arrangements, we shall proceed to discuss the facts bearing on the general sanitary condition of the province in 1882.

4. Excluding certain districts, from which accurate returns cannot at present be obtained, the population of British Burma in 1881 consisted of—

Males	1,952,530
Females	1,711,393
Total	3,663,923

Of this population, 425,775 were located in 20 towns, and 3,238,148 in country villages, of which there are 14,942; facts which prove that Burmese sanitary work is essentially village work, and that the present proceedings in the towns, if all were successfully terminated, would leave the bulk of the population without sanitary care.

The population of 1881 was made up of the following classes:—

Mahomedans	168,766
Hindus	87,902
Christians	83,604
Burmese or Buddhists	3,217,023
Other classes	106,628
Total	3,663,923

The Census population of 1881 showed an increase of no less than 35 per cent. over the population of 1872, much of this large increase being apparently due to immigration into British territory.

5. The births in 1882 were of—

Males	41,781
Females	39,067
Total	80,848

If the whole 10 years' births were added to the Census population of 1872, and no deaths deducted, the total would still fall short of the Census number of 1881.

6. The following deaths were registered in 1881:—

Males	32,509
Females	26,637
Total	59,146

The death-rate was 16·44 per 1,000, and the birth-rate was 22·07 per 1,000, so that if both rates were reliable there would have been an addition to the population of the province in 1881 of 5·93 per 1,000.

Registered death-rates differed materially in towns and in country districts. In the 20 towns the death-rate from all causes in 1882 averaged 26·02 per 1,000 against a previous five years' average of 30·14 per 1,000. In the 15 districts, on the other hand, the death-rate in 1882 was only 14·84 per 1,000 against a previous five years' average of 14·80.

Registration appears to be better done in town than in country circles. In both, the figures probably represent the registration accuracy already attained rather than the actual facts. But, no doubt, the registration machinery is improving.

The town death-rate of 26·02 per 1,000 was under the five years' average, which was 30·14 per 1,000. The lowest rate, 16·84 per 1,000, was returned from Thyetmyo, and the highest, 39·2 per 1,000, from Pantanaw. The Thyetmyo death-rate was apparently much under the truth, for its five years' average rate had been 31·62 per 1,000.

7. The following were the census data for 1881, together with the areas and death-rates for 1882 and preceding five years, for each rural district, excluding towns:—

Districts.	Area in Square Miles.	Population 1881.	Death-rates.		Villages in Districts.
			1882.	Previous Five Years.	
Akyab	5,535	325,717	18·93	19·20	1,929
Kyoukpyoo	4,309	149,303	19·76	20·39	937
Sandoway	3,667	64,010	16·89	20·51	469
Hanthawaddy	3,106	420,667	13·41	15·99	1,382
Tharrawaddy	1,198	271,044	9·90	No data	1,045
Prome	2,010	260,914	17·96	14·50	1,548
Thonegwa	5,413	265,216	15·15	12·25	978
Bassein	5,833	349,365	15·17	12·19	1,644
Henzada	1,948	288,372	18·94	13·55	1,231
Thyetmyo	2,397	147,638	15·92	23·39	872
Amherst	15,203	301,086	8·42	10·96	1,021
Tavoy	7,150	71,616	16·85	12·04	291
Mergui	7,810	47,926	11·92	12·13	200
Shwaygyin	5,587	163,625	12·10	15·30	559
Toungoo	6,354	111,649	12·86	12·73	836
Totals	77,500	3,238,148	14·84	14·80	14,942

These statistical data, together with the data for the 20 towns and their population of 425,775, show at the commencement of a new decennial census period the nature of the sanitary and registration problems which have to be dealt with in Burma, and we have introduced them here to show the need of a far more efficient superintendence of sanitary work than can be afforded by frequent change of the sanitary authority. We admit the difficulties, but our duty is to point out the apparent inadequacy of the means at present in use for dealing with the obvious necessities of the case.

8. *Chief death causes in* 1882:—

Diseases.	Total Deaths, 1882.	Deaths per 1,000.	
		1882.	Five Years' Average.
Cholera	7,177	1·96	1·52
Small-pox	770	0·21	0·77
Fevers	27,093	7·39	8·70
Bowel complaints	3,291	0·90	1·43
Injuries	601	0·16	4·18
All other causes	20,214	5·52	
Total	59,146	16·24	16·60

These data, like those already adduced, appear to show rather an average condition of the registration than a definite statistical account of the sanitary history of this Province.

We shall next give a brief account of each death cause from the Sanitary Commissioner's Report.

9. *Cholera.*—The death-rate from cholera in the towns exceeded the country rate by 1 per 1,000. It was 2·84 in the former districts, and 1·84 in the latter. The total rate varies considerably in different years, as is shown by the following annual abstract of deaths for 11 years. But, so far as the registered deaths show, there is not the same tendency to regular periods of increase and decrease as take place in India.

Years.	Cholera Deaths.	Years.	Deaths.
1872	640	1878	6,759
1873	8,109	1879	1,828
1874	960	1880	2,638
1875	761	1881	5,239
1876	3,678	1882	7,177
1877	7,276		

Allowance must apparently be made for defective reporting of cholera deaths, in arriving at an estimate of cholera mortality in individual years.

The epidemic of 1882 did not follow the same law of increase in all the districts, as is shown by the following monthly abstract of deaths in each division. The average monthly rainfall in each division is also given to show the relation between the two classes of data :—

Months, 1882.	Arakan.		Pegu.		Irrawaddy.		Tenasserim.	
	Deaths from Cholera.	Average Rainfall.	Deaths from Cholera.	Average Rainfall.	Deaths from Cholera.	Average Rainfall.	Deaths from Cholera.	Average Rainfall.
		Inches.		Inches.		Inches.		Inches.
January	1	0·4	102	—	54	—	157	0·24
February	—	—	8	1·63	137	0·43	39	0·68
March	—	—	55	—	283	—	38	2·15
April	—	3·16	270	2·20	290	1·22	78	5·47
May	2	10·79	104	5·74	374	5·28	62	11·73
June	—	55·63	125	10·77	478	13·90	24	39·6
July	42	55·16	782	17·36	478	12·82	24	42·2
August	159	42·9	429	18·89	122	11·53	35	34·82
September	183	17·40	88	19·88	55	11·4	114	26·76
October	145	8·46	49	6·64	61	4·27	246	11·2
November	103	1·75	87	1·32	175	1·16	236	2·81
December	403	2·45	142	0·68	383	0·19	245	—

This table does not show a constant relation between rainfall and cholera prevalence. In Pegu and Irrawaddy, cholera diminishes with heavy rain, but in the other two divisions it increases.

The monthly incidence of cholera for the whole province was as follows :—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	314	July	1,326
February	184	August	745
March	376	September	450
April	638	October	561
May	542	November	601
June	627	December	373

When this table is compared with the divisional average rainfall there is an apparent diminution of mortality after the rains, but the data are uncertain, and the real effect of rain on the mortality from cholera and fever may have to be sought in very circumscribed localities in a country where the rainfall is excessive.

10. The incidence of cholera in 1882 presented the usual features. Deaths from it were returned from 143 circles of registration out of a total of 850; and 13 out of 15 registration districts registered deaths. Cholera was sown broadcast over the Province, but the whole 7,177 deaths were reported from no more than 232 population groups, while 14,710 escaped the disease. Out of 20 towns 19 were attacked, pointing clearly to the probable influence of locality and local causes.

These 19 town population groups yielded 1,211 deaths, while the whole country groups yielded 5,966 deaths.

11. It cannot be said that the Report under review gives an account of the circumstances attending this epidemic. Two or three remarks by medical officers are introduced, but they throw no light on the subject. There is one report by Dr. Dalzell, however, which may be quoted, because it gives the only information on the relation of local causes to cholera prevalence. It relates to Akyab. "There were 42 (43) deaths from cholera reported during the year. The number of "cases which actually occurred were not ascertained, as apparently deaths only were reported. "The origin of the disease is difficult to trace; as it occurred among the residents, there was no "evidence of importation. One isolated case occurred in January, and the disease did not make its "appearance again till May, when another single death was reported. I am strongly inclined to the "belief that neither of these were cases of real cholera. In September the disease broke out "in the form of a circumscribed and local epidemic in the Mawleepara division of the town. I "visited several of the houses where the disease first occurred, and satisfied myself as to its true "nature and extent, and endeavoured to ascertain its cause. I found the locality (which was "extremely crowded) in a very filthy condition; the drains were choked up with sewage matter, and "the enclosures were in a swampy and unwholesome condition; the state of the well in one of these "compounds has already been described in a previous paragraph. I at once communicated the "result of my investigations to the magistrate, and recommended that a gang of conservancy coolies "should be sent to the spot, with orders to clean the drains and remove filth and rubbish from the "neighbourhood of the affected locality, and also that the well above alluded to should be closed. "My recommendations were promptly carried out, and we had the satisfaction of seeing the "epidemic gradually die out." The medical officer evidently did what he could, but the question

for the sanitary administration is simply this, "Why was it not all done before?" Why was it necessary to wait until this foul state of matters had done its work before the "conservancy coolies" were sent into the locality?

12. *Small-pox.*—The following abstract gives the deaths from small-pox in Burma since 1872:—

Years.	Small-pox Deaths.	Years.	Small-pox Deaths.
1872	845	1878	1,406
1873	1,416	1879	2,297
1874	1,191	1880	5,402
1875	752	1881	1,766
1876	1,335	1882	770
1877	1,230		

In 1882 these 770 small-pox deaths were returned from all the 15 districts, with two exceptions, Tavoy and Mergui; but out of 850 circles of registration only 30 reported deaths, and these deaths all took place in 35 villages out of 14,942 in the Province. It would hence appear that the year's mortality was due to 35 endemic outbreaks of small-pox, in which the average deaths exceeded the high proportion of 20 per village or population group. The country circles yielded 651 deaths, 0·20 per 1,000 of population; and the towns, six of which out of 20 returned deaths, had 119 casualties from this disease, or in the ratio of 0·28 per 1,000.

The monthly mortality in 1882 was as follows:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	70	July	43
February	75	August	41
March	97	September	38
April	95	October	32
May	120	November	47
June	91	December	21

13. The vaccination establishment for the official year 1882–83 consisted of—

Superintendent General	1
Superintendents of circles	17
Native ditto	4
Vaccinators, 1st class	17
Ditto, 2nd class	45
Chuprasies, &c.	2
Total	86

The following was the relation of vaccinations to births:—

Births	80,848
Total vaccinations	55,095
Of which successful	44,704

or about 55 per cent. of the births.

The re-vaccinations were 2,713, of which 1,639 were successful. The vaccinations amounted to 12½ per 1,000 of population.

One of the tables gives the results of vaccination and small-pox for 5 years for each of the divisions of Burma, as follows:—

Divisions.	Population, 1881.	Average Ratio per 1,000 for Five Years.	
		Vaccinated.	Died of Small-pox.
Arakan	487,518	8·37	0·18
Pegu	1,162,393	19·97	1·46
Irrawaddy	1,161,119	9·79	0·88
Tenasserim	795,732	10·83	0·48

The results are not satisfactory. The successful vaccinations are apparently too few to show any influence on reduction of small-pox mortality, and it must also be borne in mind that medical officers complain of the prevalence of inoculation in their districts. The most practical suggestion as regards small-pox is one made by the civil surgeon of Akyab. He proposes to appoint officers of

circles to do the vaccination work, to conduct the registration, and to attend to sanitation. But the Sanitary Commissioner, while admitting the importance of the proposal, says that the cost would be prohibitory.

This proposal, nevertheless, includes a principle for which we have often contended, namely, that the vaccination staff should do sanitary inspecting and advising work for villages while on their tours of duty.

14. *Fevers.*—In dealing with the fever mortality, the usual difficulty about diagnosis recurs in Burma as elsewhere in the East. The present Report repeats the statement that deaths preceded by heat are classed as fevers. As we have suggested before now, it might get over the difficulty if persons charged with registration were directed to include under the term "fever" only those cases attended by paroxysms.

Fever deaths in country districts were 23,487 in number, or 7·25 per 1·000 of the population. In the towns, 3,606 fever deaths, or 8·47 per 1,000, were registered. The fever death-rate for the whole Province was 7·39 per 1,000,—a very low rate, even if we take no account of errors in diagnosis.

15. The Sanitary Commissioner has given the following table, showing the monthly relation of fever deaths to climate:—

Months.	Fever Deaths.	Humidity Average.	Mean Temperature.			Rainfall.
			Max.	Min.	Range.	
			°	°		Inches.
January	2,212	69·77	86·15	60·58	27·7	0·19
February	1,806	64·15	89·44	63·48	26·1	0·72
March	1,757	55·90	94·17	69·02	24·6	0·42
April	1,714	60·22	94·93	74·04	20·2	3·45
May	1,725	87·22	91·84	75·34	15·4	9·45
June	2,111	85·77	87·39	75·35	14·7	32·35
July	2,737	86·77	85·31	75·22	9·6	34·27
August	2,784	88·31	85·24	74·86	9·9	28·97
September	2,674	84·15	86·56	75·02	11·3	20·70
October	2,421	82·85	87·86	74·83	12·9	8·39
November	2,431	74·59	87·45	71·26	16·3	2·09
December	2,676	68·38	86·51	65·31	21·4	0·73

The most humid months, and those with highest rainfall accompanied by heat, were the months of highest fever mortality. Temperature range appears to have exercised no influence on this, except at the end of the year.

Deaths from fever were reported from all the districts, and from 564 out of 850 circles of registration. Fever covered the whole area of the country, more or less, but it was nevertheless strictly endemic, for the whole fever mortality of the year was yielded by 1,377 out of 14,942 population groups. On several occasions we have called attention to the low fever death-rate of Burma, but these facts appear to show that the real cause of this apparent low rate may be due to bad registration. Why should the whole death-rate have been yielded by less than a tenth of the population groups, and why should upwards of nine tenths have escaped? The fever causes, as the table show, were operative over the entire area of the Province, and yet we have the anomaly of their being inoperative, so far as mortality is concerned, for nine tenths of the population probably.

The only statement of local causes is the following:—"As in the previous year, July, August, " and September was the quarter which returns the greatest mortality. At that season, the whole " country, especially the delta, is water-logged; water in wells rises to within a foot or two of the " surface; atmospheric humidity is then most pronounced." If the registration were more reliable, this question might admit of further discussion, but we have shown that the foundation facts are wanting. As the case stands, the delta districts by no means yield the highest death-rates from fever.

The year's rate, as already stated, for the whole Province was 7·39 per 1,000 against a previous five years' ratio of 8·70 per 1,000. The delta districts had a fever rate for the year of 5·93 per 1,000, and the north-western sea-side districts of 13·23 per 1,000, viz., where the rainfall is heaviest the fever death-rate is highest. The rainfall in 1882 was there about 200 inches.

16. *Bowel complaints* yielded 3,291 deaths in 1882, or 0·90 per 1,000 of the population, against a previous five years' annual average of 1·43 per 1,000. Of these deaths 864 took place in the towns, equal to a ratio of 2·03 per 1,000 of the town population; and 2,427, or a death-rate of 0·75 per 1,000 of population, were returned from country circles. But we have here the same anomaly as in other diseases, viz., that while cases of fatal bowel complaints were returned from all the districts, they were registered in 131 circles only out of 850 in the Province and from 148 villages out of 14,942. These facts show how much registration requires to be improved.

The following were the monthly deaths from diseases classed under this head :—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January - - -	329	July - - -	434
February - -	156	August - - -	483
March - - -	150	September - -	322
April - - -	221	October - - -	227
May - - -	239	November - -	234
June - - -	306	December - -	290

This table merely shows how many deaths were registered each month. Nothing else can be deduced from it.

17. *Injuries.*—Deaths registered under this title included 72 suicides, 323 wounds and accidents, and 206 deaths from snake-bite and wild beasts.

18. Under *all other causes* were registered 20,214 deaths, or nearly a third of the total mortality of the year.

The circumstances under which registration in Burma has to be carried out are of well known difficulty, and continuous efforts have been made to ensure greater accuracy of record and report, but from the facts we have dealt with, it will be seen that at present only a general idea of the disease history of this Province is available for sanitary work.

19. *Sanitary Works (Civil).*—Under this head are given a number of notes on sanitary works carried out during the year in certain of the towns, together with remarks on the registration as it exists at present. The details are without arrangement, and the general impression conveyed by them is that while vaccination and registration are considered necessary, especially the first of these, real sanitary work for the removal of disease causes is a matter not of primary importance, to say the least of it. All we can do with the data is to abstract from them such information as they contain on this subject.

Rangoon.—"The splendid waterworks by which the town is to receive an ample supply of pure "water have made rapid progress during the year, and will be soon completed. . . . The "executive engineer expects to have an almost unlimited supply of water by the end of August "1883." It has, however, been possible in the meantime to extend the supply to the town proper; and as drainage works had not proceeded *pari passu* with the water-supply, we are told that "there is an immense increase of the house sullage in consequence of the better supply of water "to the town. . . . . The open roadside drains are the channels through which most of it "flows; a vast amount is thrown on to the land in the drainage spaces, which, in consequence, are in "as bad, if not worse, condition than they were last year. In streets where the roadside drains are "not lined with bricks, there has been an aggravation of the evil, the sullage remaining in the "ditches stagnant and stinking. . . . . At present the roadside drains are the receptacles of urine "from stables, and often from coolie barracks, and of course there is in the dry weather much "ground of complaint from the stench thus caused." There is a drainage scheme in hand "which, it is hoped, will be started on the completion of the waterworks."

No information as to this proposed scheme is given in the present Report, and we can give no opinion about it, except that, with an almost unlimited water-supply, there ought to be no difficulty in laying down a drainage system sufficient to cleanse every house in the town, and to leave nothing to be carried away by hand labour except town sweepings and food refuse.

It is a fundamental principle of all town improvements that works of drainage should go on *pari passu* with the water-supply, to prevent the added water becoming an added disease cause. Such a state of matters as the following extract describes ought to cease when the town is drained:—"Some "improvements in the system of collecting house refuse is much needed. Stale rice, vegetables, "fish refuse, &c., are now either thrown into the drain in front of the house, or on the drainage "space." The present difficulties in dealing with public and private latrines ought also to disappear under a suitable drainage system.

Attention is pointedly called to evils of another kind, resulting from the large influx of Madras coolies as labourers into Rangoon. They are described as "the most dirty of the many various races "in this city, and the most difficult to deal with." The houses where they live "are always reeking "with filth, and generally are the centres of nuisances, bad smells, and diseases of their neighbour-"hood."

The following comment accompanies this statement:—"This is one of the numerous instances in "which the hands of the sanitary officer are tied by inefficient byelaws, framed under an Act which "has been pronounced by the legal adviser of the municipality and the magistrates to be inoperative." In other words, we have here an Act which practically arrests sanitary work. Why not rescind it, and pass another? No wonder there are so many weak places in the sanitary administration.

Akyak town.—No sanitary report. Municipal report (not given) stated to have been submitted by the President. Inhabitants of some villages have been instructed as to the necessity of sanitary precautions.

Bassein.—A few surface drainage improvements. Nothing else of consequence done. The income of this town of 5,355 inhabitants is stated at Rs. 7,800, and the expenditure at Rs. 14,000.

Sandoway.—Income, Rs. 14,600. Expenditure sanctioned for surface sanitary work, Rs. 460. "No public latrines; the river answers the requirements of the people in all respects." The river also receives all rubbish and sweepings.

Mergui.—Population, 8,633. Income, Rs. 7,145, most of which was spent on sanitary work, roads, wells, drains, conservancy. An original way of protecting wells is shown on a section. The well tube is raised about 5 feet above the ground, and surrounding this there is an outer wall half the height, leaving a circular space of about 3 feet between the walls, which is filled up with sand. It is not easy to see of what use this method can be, because it leaves the main cause of impure well water, the impure subsoil, where it was. In our "Suggestions" we have shown how this cause can be effectually dealt with.

Shwaygyin.—Population, 7,519. Income, Rs. 22,100. Expenditure, Rs. 29,500, of which Rs. 2,917 were spent on sanitary works, mainly conservancy. There are no public latrines. Cesspits are in use. Water-supply chiefly from wells. As we have often pointed out, wells under such conditions can never be safe as water sources unless all cesspits be abolished and filled up, and the whole sewage removed daily by hand labour.

Tavoy.—Population, 13,372. Expenditure for sanitary purposes, Rs. 2,513 out of Rs. 22,500 expended during the year. Surface work only done. Water-supply bad.

20. The sanitary information which it has been deemed sufficient to give about these smaller towns is practically reproduced in regard to the others of which any notice is taken. Drainage is provided for surface water only. Cesspits, wells dug in the same ground, and bad or indifferent water, appear to exist in most of them. Nevertheless, some current sanitary work is carried out in most of these towns, but all that can be said about them is that they are beginning to improve their sanitary condition. The chief large works in progress were the water-supply of Rangoon and the drainage and water-supply of Prome.

21. Municipal funds are now administered by committees, the majority of the members of which have been elected by the townsfolk. In the course of the year municipal committees were formed in 24 towns. Sanitary work is thus entering on a new phasis, and this is the time to systematize it, to prevent wrong courses being followed, and to exercise skilled supervision over the whole.

22. We would, in view of this change, strongly advise that the office of Sanitary Commissioner should cease to be held as a movable appointment. It is true that the work can be left to develop itself, and very probably in wrong and expensive directions; but if the Sanitary Commissioner is to be responsible for the supervision of the work under its altered conditions, it is clear that he must be able so to arrange his medical and sanitary duties as to gain knowledge and experience on the spot, and that village work should be placed under his supervision also. We have stated in our revised "Suggestions" the chief points to be attended to, both in towns and villages, and to them we must refer for practical details.

23. The main recommendation we have to make on the Report under review is what we have stated in regard to the need of efficient direction and supervision being bestowed on the work in such way as the Government may consider best. More attention might also be paid to systematic sanitary reporting, so that the precise state of towns and villages might be reproduced from time to time, bearing in mind that reporting is only a means to an end, and that the most acceptable reports are those which tell of good sanitary work done and lives saved.

18th January 1884.

No. 11.

Memorandum of the Army Sanitary Commission on the Sanitary, Vaccination, Dispensary, and Jail Report of Rajputana for 1882.

This Report is in the form of a selection from records of the Government of India, Foreign Department, and is not in the form adopted for the sanitary reports of Provinces. It, nevertheless, contains a number of important facts and particulars, which show that the public health movement is taking hold of opinion, and is not unlikely to make progress among the people at no distant date.

1. The vital statistics of Rajputana are based on the census of 1881, and are divided into two sections, Ajmere and the Native States. In the former the data are collected in the usual way, and in the Native States the data are supplied by the courtesy of the durbars, who in this matter are performing an important public service.

The Ajmere data are the more complete, and we hope that the details for the Native States will before long be brought up to the same standard.

2. The population of Ajmere and Merwara in 1881 stood as follows:—

Mahomedans	57,809
Hindus	400,337
Christians	—
Other classes	2,576
	460,722

The sexes of this population are not distinguished in the returns, but they are distinguished in the birth and death registration as follows:—

Births registered.	
Males	6,336
Females	5,520
Total	11,856 = 25·73 per 1,000.

Deaths registered.	
Males	4,761
Females	3,804
Total	8,565 = 18·59 per 1,000.

The previous five years' death-rate was 25·23 per 1,000, showing apparently some falling off in the death registration of 1882.

The death-rates per 1,000 registered among different classes were as follow:—

Mahomedans	15·65
Hindus	18·82
Other classes	1·94
Total	18·59

3. The following were the deaths registered under the usual headings in 1882 in Ajmere and Merwara:—

Death Causes.	Total Deaths.	Deaths per 1,000.
Cholera	289	0·63
Small-pox	718	1·56
Fever	5,380	11·68
Bowel complaints	810	1·76
Injuries	242	0·52
All other causes	1,126	2·44
All causes	8,565	18·59

We have shown in other memoranda that cholera prevailed as a severe epidemic over a large area of India, and Ajmere also suffered. During the previous year, 1881, there were only 16 cholera deaths in the Province; and while the cholera death-rate during the previous five years had been 0·16 per 1,000, the rate was 0·63, or nearly fourfold this average, in 1882. Out of 23 circles of registration, 15 returned cholera deaths; but, as usually happens in India, all the deaths were returned from no more than 38 population groups out of 739, or a little over 5 per cent. of the number.

4. The monthly distribution of cholera was as follows:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	—	July	61
February	—	August	103
March	1	September	69
April	6	October	—
May	3	November	—
June	48	December	—

These figures show that a distinct epidemic wave passed over the Province in the middle of the year.

The district population of 370,391 yielded 264 deaths from cholera, or in the ratio of 0·71 per 1,000; and the town population of 90,331 had 25 deaths, or 0·28 per 1,000. One of the towns, Pisangan, returned no deaths from cholera.

The epidemic fell with greatest severity on Ajmere rural district, where, out of 21,933 people, there were 138 deaths, or 6·29 per 1,000. This was the highest rate of the year. Ajmere town district had a rate of 5 per 1,000, but the town itself yielded 15 deaths out of a population of 40,559, or in the ratio of 0·37 per 1,000. The weight of the epidemic thus fell on the Ajmere circles, while the town itself comparatively escaped.

5. The following account of the Ajmere outbreak appears to have been carefully drawn up, and is worthy of quotation, as showing how cholera comported itself within a limited population where the facts could be ascertained:—"A death from cholera was reported by the police to have occurred "in the Kekri rural district, in the village of Oondri, on the 9th March. So far as can be "ascertained, this was the first case. On the 11th April two women arrived in Ajmere, very ill, "by rail from Ahmedabad, and died of cholera on the same day. The house where they lodged "was disinfected in the usual way. During the remainder of April, and throughout the whole "of May, no seizures took place in the vicinity of the city or in the rural district of Ajmere, "though seven deaths were reported by the police as having occurred during these months in towns "and villages at varying distances from the capital. On the 10th of June the disease appeared in "an epidemic form among some coolies, who were living in huts much overcrowded in the suburbs "of Ajmere. From this time fresh cases frequently occurred until the 18th August, from which "date cholera entirely disappeared from the city and its immediate neighbourhood. Cases continued "to occur in the outlying districts until the 26th September, after which date no more seizures took "place." Jails and troops escaped, a water carrier only having been attacked. No account is given of the localities where these cases occurred.

6. *Small-pox.*—Deaths from small-pox were registered in all the 23 circles, and in 164 villages out of 732 in Ajmere and Merwara. The towns were more severely affected by it than the rural circles. Out of a town population of 90,331 there were 148 small-pox deaths, or 1·64 per 1,000, while the country population yielded a rate of 1·54 per 1,000.

The year's rate for the whole Province was 1·56 per 1,000 against a previous five years' average of 2·58 per 1,000.

The monthly numbers of small-pox deaths stood as follow:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	42	July	52
February	36	August	24
March	89	September	7
April	152	October	7
May	146	November	20
June	113	December	36

7. The vaccination service consisted of six vaccinators, under superintendence of the Civil Surgeon and a Native Superintendent. The year's work consisted of 4,594 successful vaccinations, far from being equal to the births, which numbered 11,886.

8. *Fevers.*—As in other Governments of India, fevers were by far the most important death causes in Ajmere. There were 5,380 deaths assigned to this cause, equal to a death-rate of 11·68 per 1,000, against a previous five years' average of 15·31 per 1,000. All the 23 circles of registration returned fever deaths, and 704 villages out of 739 suffered. All the towns registered deaths from this cause.

No account is given of the local causes of fever; and the following monthly deaths appear to show that the amount of fever is not so strikingly influenced by merely climatic causes as it is in other districts of India; but there is still more fever in the drying-up season:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	481	July	356
February	365	August	569
March	345	September	618
April	335	October	541
May	368	November	499
June	334	December	569

There is nothing in the remainder of the year's disease history of Ajmere specially calling for notice.

9. *Native States.*—The census of 1881 was the first general enumeration made under British rule. The population of two states and five cities from which births and deaths have been returned amounted at that date to 1,294,319.

The registered births were of—

Males	4,283
Females	3,333
Total	7,616 = 5·88 per 1,000.

There were 14,941 deaths registered = a ratio of 11·54 per 1,000.
A very hopeful commencement has therefore been made in this important public work.
Deaths were registered as follows:—

Diseases.	Deaths.
Cholera	573
Small-pox	571
Fevers	4,935
Bowel complaints	535
Snake bite	34
Injuries	68
All others	8,225
	14,941

Vaccinations in the Native States are returned as 105,642 successful.

10. *Sanitation.*—In Ajmere division no sanitary work had been carried out. The method of cleansing had been under consideration by a local committee, which had decided that the town filth should be removed to a distance by rail, unless the cost stood in the way. Should this prove to be correct, some other means of removal would be adopted. The Ajmere water-supply scheme had been delayed on account of an accident during the rains, "and it is now uncertain" when the works will be completed.

The most satisfactory proceeding during the year appears to have been the examination of the vaccinators on Dr. Cuningham's sanitary primer, and these officials were instructed "to take every opportunity of spreading information regarding the laws of health among the villages."

11. A similar course has been adopted with the vaccinators in the Native States, and it is very satisfactory to be told that some movement in the way of improving the public health has begun in several localities. For example, in Jeypore the durbar has under consideration the introduction of the dry-earth system in combination with street tramways to facilitate the removal of sewage. The streets have been named; the houses numbered; some of the Ajmere registration forms have been introduced for births and deaths; and two city inspectors have been appointed. This city had a population of 142,578 in 1881, so that the introduction of conservancy on a definite plan among so many people is a work of no ordinary importance, and we must hope that the financial part of this proposal may be also met.

Ulwur city is a State capital, and has a population of 49,867. While attention has been paid to the city, the Surgeon-Major remarks that "special efforts were made this year to spread amongst the "people some knowledge of the importance to them of improvements in their sanitary surroundings. "Vaccinators were compelled to read up Surgeon-General Cuningham's Sanitary Primer, and to "show themselves able to explain to the villagers the broad principles it teaches. Tehsildars and "other district officers were instructed by circular from His Highness the Maharaja's office that they "were bound to see that some improvement in sanitary matters was stated in their respective "charges."

Attention was particularly called to the protection of drinking water from pollution, and of the necessity of marking off certain spots "to leeward of the village for manure heaps, and for the "purposes of nature. The Agency Surgeon states that during his tour he saw evidence "even in out-of-the-way places that these instructions were being attended to." His Highness the Maharaja was very properly thanked "for the substantial assistance afforded to the endeavour to "spread throughout the State some knowledge of the laws of health." A primer is about to be introduced into the State schools.

Of *Oodeypore* it is said that "the prevalence of cholera in this State during 1882 has not proved "an unmixed evil, for the epidemic had the effect of calling attention pointedly to some of the "sanitary requirements of the city." Refuse has been collected into heaps and burnt, and the ashes sold to cultivators. Vacant spaces have been set apart for purposes of nature, and for collecting manure, &c. Several surface drains have been made, and a jemadar, with a staff of 115 sweepers, has been appointed to attend to the sanitary arrangements. This city contains a population of 38,214. In other localities in these Native States similar work is being done. All this is matter of satisfaction, and we must hope that these examples may be followed in other places.

No doubt, as stated in the Report, old habits and customs are difficult to change, but the facts show that with care and judgment an important commencement in applying sound principles in practice has been already made.

12. *Jails.*—The average number of prisoners in the jails of Ajmere division was 495, and the death-rate in 1882 was 26 per 1,000. In the Native States the average prisoners amounted to 2,662, and the death-rate 36 per 1,000. Both rates are high, but the Native jail rate is the lowest of five years' rates.

It is worth while to place the rates side by side:—

Years.	Death-rates per 1,000.	
	Ajmere Jails.	Native Jails.
1878	45	160
1879	35	103
1880	10	48
1881	4	46
1882	26	36

The first year in the series was a scarcity year, during which there was a large increase of prisoners. There has been a continuous reduction of average inmates in the Native jails from 3,534, the maximum average in 1878 to 2,662, the lowest number in 1882. But in the Ajmere jails the number rose from 429 in 1881 to 495 in 1882. These facts appear to show that the element of crowding entered into the chain of causes of annual death-rates. It is satisfactory to learn that various sanitary improvements have been or are being effected in different jails. A new jail will be erected at Oodeypore, and another at Tonk. These are important improvements, for we are told that "since the occupation of the new jail at Kotah the number of fatal cases has steadily declined." 39 per cent. of the mortality in Native jails arose from bowel complaints, and 16 per cent. from malarial fevers.

13. *Dispensaries.*—These establishments are of a departmental character, and do not call for remark, but we cannot conclude this Memorandum without alluding to the provision made for sickness. We find from the tables, that in the Ajmere dispensaries there were treated in 1882, 740 indoor and 37,541 outdoor patients, while the Native States dispensaries treated 4,175 indoor and 275,066 outdoor cases.

14. In a former Memorandum we took exception to the small amount of public health work reported from Rajputana, but in the preceding paragraphs it has been shown that, although very much remains to be done to save the people from epidemics, there is evidence of commencing movement in this important work, and perhaps the most gratifying part of the Report is that which shows that the necessity of sanitary improvement is becoming recognized both by the people and by Native rulers.

3rd September 1884.

No. 12.

Memorandum of the Army Sanitary Commission on the Administration Report of the Commissioners of the Town of Calcutta for 1882–83.

1. In the following paragraphs we shall first give some account of the public health in Calcutta during the year 1882; and the first point which appears to require notice is the opening paragraph of the health officer's report, which states that, "in accordance with the provisions of Act I. (B.C.) of "1882, annual reports will for the future be prepared for the official year (ending 31st March) in "place of the calendar year as heretofore." This change in a current system of health statistics which prevails in all civilised states, and which, moreover, is in contradiction with the principles of statistical uniformity aimed at by the London International Statistical Congress, cannot be otherwise than matter of regret. Annual statistics of this class have to deal with scientific points alone, and have no relation to official convenience.

The year ending 31st March cannot be accepted as giving a true account of the public health and its relations to other elements, unless the whole of these elements were recalculated on this basis. In the present state of the law, the best course, apparently, to take would be to have two sets of figures, one for the calendar year, the other for the official year, and to print both.

2. The present year's Report gives the figures for 1882, with a supplement for the first quarter of 1883, from the 31st March, of which the statistics will be reckoned hereafter. These remarks apply to all the health statistics of India, and we have introduced them partly for the purpose of pointing out the injury which would arise from the Calcutta example being followed elsewhere.

3. The following table gives the population of Calcutta according to race for the 12 months of 1882:—

Race.	Population.		
	Males.	Females.	Total.
Non-Asiatics	9,193	4,658	13,851
Mixed races	4,515	4,389	8,904
Hindoos	189,684	98,678	288,362
Mahomedans	90,667	33,763	124,430
Other classes	4,358	2,314	7,282
Total	288,317	144,402	433,219

This table presents the usual anomaly of the male population being double that of females, showing, apparently, that many families live beyond municipal limits, while the husbands lodge in Calcutta for convenience of work. But the discrepancies between the sexes are partly due to the fact that in the preceding totals are included 3,002 males against 346 females in Fort William, and 28,037 males against 163 females in the Port population.

If both be deducted, the population of Calcutta registering sections will be:—

Males	257,778
Females	143,893
Total	401,671

4. Among this population the births registered in 1882 amounted to 7,505, or 17·3 per 1,000, and the deaths to 13,177, or 30·4 per 1,000, against 29·3 per 1,000, which was the previous 10 years' average.

This comparison is not a satisfactory one, but, even high as the rate is after the sanitary work which has been carried out, there is nevertheless abundant proof of the saving of life within the precincts of municipal Calcutta by comparing its death-rate with the rate which prevailed in 1882 among above 250,000 people in the suburbs beyond the influence of sanitary work. The deaths in the suburbs were 10,470, or 41·6 per 1,000; and this ratio showed a great reduction, chiefly in fevers, bowel complaints, and other causes, over the previous five years' suburban average, which was 53·8 per 1,000. Notwithstanding the higher town rate of 1882, it also showed a reduction over the previous five years' average, which was 31·3 per 1,000.

During the last year or two there have, we believe, been some improvements in bustees, water supply, &c. in hand by the suburban authorities, which may have been of service, but we have no means of knowing the facts.

5. The next abstract gives the death causes within municipal Calcutta, under the customary headings, for 1882 and 1881:—

Death Causes.	Total Deaths.	
	1882.	1881.
Cholera	2,240	1,693
Small-pox	17	133
Fevers	3,618	3,765
Bowel complaints	1,454	1,491
Injuries	236	5,948
All other causes	5,612	
All causes	13,177	13,030

There were 147 more deaths in 1882 than in 1881, partly accounted for by reductions as well as by augmentations. If we take the so-called zymotic diseases, we find in 1882 an increase of 547 cholera deaths, but a decrease of 116 deaths from small-pox, 147 from fevers, and 47 from bowel complaints. The decrease in these diseases was 310, against an increase of 547 from cholera.

There was an increase of 100 deaths under all other causes. We are thus brought to augmentation of cholera as the real cause in the rise of Calcutta death-rate, for if the cholera rate had been the same in both years the death-rate of 1882 would have been a shade lower than that of 1881. We

can go a step further in this analysis by comparing the cholera death-rates for the last five years in municipal and suburban Calcutta, which have stood as follow:—

Years.	Cholera Deaths per 1,000.	
	Calcutta.	Suburbs.
1878	3·0	9·3
1879	2·7	7·4
1880	4·8	8·8
1881	3·9	7·4
1882	5·7	9·3

This table affords evidence that, both in the improved and unimproved areas, the cholera mortality is determined by epidemic intensity as well as by local sanitary condition. But the influence of local causes on the mortality is strikingly shown at the same time by contrasting the annual rates of improved municipal Calcutta with the rates of the unimproved suburbs; and the practical lesson taught by the facts is that, whatever may be the intensity of a cholera invasion, the loss of life from it is greatly augmented by bad sanitary condition.

6. In our Memorandum on the Calcutta Report of 1881 we dwelt strongly on imperfect cleansing as a probable cause of increasing cholera mortality shown in the preceding table, but since that date there has been a great epidemic of cholera in Lower Bengal; in other words, there was in 1882 a notable increase of epidemic intensity, and municipal Calcutta showed the highest cholera death-rate of many past years.

The Officer of Health has shown that this increase included in it rural districts around Calcutta, and there is hence every reason to believe that the same lethal influence permeated the city and suburbs, and that their respective death-rates from cholera showed the results of their comparative insanitary conditions. The whole argument from the cholera of 1882 results in no discouragement so far as sanitary works are concerned. On the contrary, their efficacy in lessening pre-disposition among the inhabitants of municipal Calcutta to cholera when it is over the country has been satisfactorily established, while the experience affords every encouragement for pressing forwards every required improvement; and, as we formerly stated, the most important work, under present circumstances, is rigid attention to cleansing and keeping clean, and the speedy provision of wholesome water for the whole bustee population.

7. As the year 1882 was an epidemic year, it may be useful to give a tabular comparison between the chief climatic elements and the monthly cholera deaths as follows:—

Months.	Mean Temperature.	Temperature Range.	Humidity.	Rainfall.	Cholera Deaths.
				Inches.	
January	67·3	22·5	73	0·13	129
February	70·2	22·8	69	3·42	121
March	80·0	23·2	67	0·52	170
April	83·4	21·5	67	0·25	318
May	83·4	19·3	71	6·05	380
June	83·8	12·2	84	9·99	254
July	82·8	10·1	86	11·76	54
August	81·8	9·8	88	10·87	52
September	82·5	10·2	86	10·50	38
October	79·0	11·7	84	11·08	91
November	73·1	14·2	75	1·61	232
December	66·3	19·9	73	—	411
Mean, 1882	77·8	16·4	77	66·18	2,240
Mean of 24 years	79·2	—	75	66·38*	1,341†

*, Mean of 48 years. † Mean of 40 years.

This abstract shows increase of cholera deaths with rising temperature and little rain; great reduction of cholera mortality with increase of rain; great increase of cholera with cessation of rain and increasing range accompanying reduction of temperature. The element of air humidity appears to exert little influence on cholera, the actual amount of which appears to be more connected with the rainfall than with any other element.

8. We shall next trace the distribution of epidemic death-rates in different districts of Calcutta, selecting for this purpose cholera and fever, as being of most importance.

Registering Sections.	Population.	Persons per acre.	Deaths per 1,000.		
			Cholera.	Fevers.	All Causes.
Shampookur	25,487	78	6·1	8·8	35·9
Coomertooly	25,682	129	7·3	6·6	29·2
Bartollah	25,527	85	5·7	9·0	32·8
Sookia Street	20,572	89	5·8	8·5	35·4
Jorabagan	36,318	148	7·2	8·3	33·3
Jorasanko	32,824	131	6·1	9·0	37·1
Burra Bazaar	20,769	100	6·8	10·5	33·1
Colootolah	47,323	208	5·1	10·1	32·6
Moocheepara	39,241	148	5·3	8·0	30·0
Bow Bazaar	21,627	150	5·3	8·5	31·1
Puddopookur	20,516	124	4·3	8·1	30·5
Waterloo Street	5,785	28	3·9	5·1	17·6
Fenwick Bazaar	26,051	137	4·7	8·0	25·4
Taltollah	26,963	125	3·2	9·8	33·7
Colliaga	11,840	70	4·2	10·3	33·2
Park Street	4,968	26	2·0	5·6	16·7
Bamun Bustee	6,125	36	2·2	14·2	31·8
Hastings Street	4,953	87	6·0	13·7	40·9
Total	401,671	107	5·2	8·8	32·0
Fort William	3,348	—	2·6	3·9	18·5
Port of Calcutta	28,200	—	4·1	4·1	15·0
Grand Total	433,219	—	5·1	8·3	30·1

This abstract connects the death-rates with one element only, namely, crowding on the surface, but in some of the least crowded districts the population is of a better class than it is in the crowded areas, and, besides this, the condition of the subsoil and general sanitary state must be considered in estimating the influence of surface crowding.

Some of the densities are, no doubt, high, such, for example, as Colootolah, containing a population of 133,120 to the square mile, which is, nevertheless, below some home averages. All the district death-rates from all causes are high, except those for Park and Waterloo Streets. With the exception of five districts which had fever-rates at and above 10 per 1,000, none of the fever rates can be considered high for India, especially for a town population.

9. The general localizing causes of cholera in Calcutta have been so often discussed that it is unnecessary to do more in the present Memorandum than to quote the result of special instances where inquiry was made by the Officer of Health in 1882. He states as the year's experience, that "In all cases in which the disease presented any tendency to grouping special investigation was "made, and in every instance in which several cases had occurred in a house or village, or within "circumscribed limits, glaring insanitary defects were discovered,—a foul tank, obstructed drainage, "fœtid ditches, ill-kept byres, offensive latrines, and so forth. Numerous cases might be detailed in "support of this statement, but the conclusion forced upon me by all that I have seen of cholera "since I became Health Officer of Calcutta is that the disease flourishes in places and among com-"munities where cleanliness is neglected, and filth of all kinds allowed to lodge and fester in various "ways and under various circumstances."

10. *Fevers.*—The fever death-rate in Calcutta appears to be undergoing gradual reduction, as may be inferred from the following number of deaths registered in 11 successive years.

Years.	Registered Fever Deaths.	Years.	Registered Fever Deaths.
1872	4,895	1878	6,086
1873	4,632	1879	4,796
1874	4,461	1880	3,797
1875	5,328	1881	3,765
1876	4,361	1882	3,618
1877	5,154		

This abstract includes the augmented fever mortality for the scarcity years 1877–78, but the general result is satisfactory, and shows the benefit of improving the condition of the subsoil of towns by under drainage. The fever death-rate in Calcutta, including districts undrained or only partially drained, was 8·8 per 1,000, or about one-half of the rate for undrained suburban Calcutta, which was 16·7 per 1,000. It is now fully admitted that the prevalence of paroxysmal fevers, which are the main causes of Indian death-rates, is chiefly due to undrained subsoil in connexion with general neglect of house hygiene.

The Officer of Health had continued his inquiries into the alleged occurrence of enteric fever deaths among the native population of Calcutta, with the result stated, "that it is quite certain that enteric fever is a rare disease in Calcutta."

11. *Small-pox and Vaccination.*—There were only 17 small-pox deaths in 1882, but safety cannot be inferred from this small mortality, as the law of prevalence of small-pox in Calcutta is that of

severe recurring epidemics, with almost complete disappearance of the disease in the intervals. During the year 1882, there were 7,802 vaccinations and re-vaccinations performed, or above one thousand more than during the preceding year. It is worthy of remark that, while the small-pox death-rate was 0·04 per 1,000 in municipal Calcutta, it was 0·09 per 1,000 in the suburbs. In the same way, the death-rate from bowel complaints, which was below the average, notwithstanding the prevailing cholera epidemic, ruled at 3·5 per 1,000 in Calcutta against 5·1 in the suburbs. As the people are the same and are really part of the same community, the argument appears to lead to the conclusion that the municipal authorities in Calcutta have done good work, and it is very much to be desired that their example may be followed outside their limits.

We shall next give a brief outline of the sanitary work in Calcutta proper in 1882, beginning with the—

12. *Water-supply.*—We may here repeat what has been said on former occasions, that the water-supply of Calcutta is pumped out of the Hoogly at a sufficient distance above the town to be unaffected by tidal influences. It is first passed into subsidence reservoirs, where it is aerated; it is next filtered and conveyed in a 42-inch main to the pumping station at Tallah, where it is forced into the mains for supplying the town.

There is another pumping station at Wellington Square, where part of the water which has accumulated during the night is forced into the mains and thence distributed for use.

There is an unfiltered water-supply raised from the river near at hand, which is used solely for street watering, sewer flushing, and the like. It may be stated as matter of home experience that iron or steel water vans are best for street watering. With a strong horse, these vans might contain 450 gallons.

Portable flush tanks, where there is a water-supply and street hydrants, will be cheaper than fixed flush tanks for flushing tributary sewers or drains.

The filtered water only is supplied for domestic purposes. Its daily amount in 1882 was 7,824,576 gallons, showing a satisfactory increase of 616,123 gallons, or in all about 18 gallons per head per diem for the municipal population. The total connexions of premises with the water mains, up to 31st March 1883, amounted to 14,245, of which 859 were made during the preceding 15 months.

13. Calcutta appears to have an active staff of water inspectors, who made, during the 15 months, 28,773 house service inspections, on which they issued 3,083 notices of defects, which were remedied in one way or other. Besides this house work the inspectors examined personally 538 stand posts, 50 ground hydrants, and 41 cattle troughs, and ordered the necessary repairs. The cost levied for water inside the town was Re. 1 for 1,500 gallons.

With the exception of a few bursts, the whole machinery appears to have worked well during the year. The supply drawn for use at Barrackpore was 48,393 gallons per day, from storage capable of supplying 120,000 gallons per day.

14. The amount of unfiltered water for cleansing purposes averaged 1,838,725 gallons per day, which is distributed from 994 ground hydrants. This unfiltered water has also been supplied to 23 premises, four for privies, six for business, one for a latrine, and 12 for building purposes. It is a very obvious recommendation to make, that house supplies of this kind should be so provided as to prevent the use of unfiltered water for drinking or cooking. The supply of unfiltered water was being extended.

15. The filtered supply is not sufficient for the wants of the population, and further extension is under discussion. A needless question has been imported into the discussion, namely, the comparative advantages of open and closed conduits, because one of the axioms of water engineering is, that water once filtered should not again be exposed to any risk of impurity before it is delivered to the consumer. The practical result has been that the Commissioners have decided to lay down a second 48-inch main, to supply 8,000,000 gallons per day additional to the town and 4,000,000 gallons per day to the suburbs. This, though a very considerable improvement, is of course far below the wants of a quarter of a million of suburban population.

16. The corporation analyst, Mr. Pedler, has given an instructive account of the filtered water-supply for 1882, from which it appears that the quality and filtration have both been improving, although the quality is subject to the influence of dry weather and rainfall, affording in this matter a kind of index to the influence of climate on tank and well waters generally.

During dry weather the solids, including chlorine compounds, are all notably increased, until the rainy weather sets in to restore the balance. Perhaps the readiest way to show the quality of Calcutta water will be to place the average analyses of 1882 alongside the corresponding facts for London water as follows:—

	Calcutta Hydrant Water, 1882.	London Water Average, 1877.
Total solid impurity	16·91	31·00
Organic carbon	0·053	0·160
Organic nitrogen	0·035	0·024
Ammonia	—	—
Nitrogen (as nitrates and nitrites)	0·021	0·328
Total combined nitrogen	0·056	0·352
Chlorine	0·91	1·80
Total hardness	7·18	19·73

Out of 103 analyses made during the official year 1882–83, the water was colourless and transparent in 67. In 36 the filtration was imperfect, but all of these defects, except one, took place during a storm.

17. Although not part of his official report, we may quote the following statement from a lecture "On the Sanitary Past, Present, and Future of Calcutta," delivered by Dr. McLeod, the Calcutta Officer of Health, on the 10th April 1884, at the Bethune Society. He says, "In quality, the water "is declared by chemical analyses to be of unquestionable purity, and Dr. Koch's microscopic "researches recently confirmed the results of analyses." Unfortunately those who used this chemically and microscopically pure water did not all escape cholera, showing that this pestilence has other origins than bad water.

18. *Drainage.*—The chairman of the Commissioners, in his interesting account of the year's drainage work, alludes to the opposition formerly raised to the drainage of Calcutta on purely theoretical grounds, the truth of which has long been disproved by the result. The entire main brick sewers of the original scheme and some more appear to be completed. These had a projected length of 33·78 miles. The actual lengths constructed are 39·21 miles. The length of pipe sewers laid down up to 31st March 1883 was about 113 miles out of 154 in the original scheme.

The secondary drainage work, namely, widening lanes and obliteration of offensive surface drains, and providing man-holes, lamp-holes, gully grates, &c., has been pushed forward rapidly, so that during 1882 there were laid 476 feet of 15-inch sewer-pipe, 1,714 feet of 12-inch, 11,354 feet of 9-inch, and 83,200 feet of 6-inch pipes, in all 18·32 miles, with the requisite man-holes, lamp-holes, &c.

The work for the first quarter of 1883 amounted to 2·35 miles of similar pipe-sewers, so that the whole original scheme, with the exception of 15 miles of pipe-sewers, has been completed. There are few municipalities which can show so much work in the time. House drainage has also been making progress. The demand for house connexions depends on the street drainage, but in 1881–82 and the first quarter of 1883 there were 4,650 houses connected with the sewers. This work is done by authorised contractors under a staff of municipal inspectors. The drainage of bustees is also in hand.

19. The sewage is passed by gravitation to the pumping-station, and during a period of 15 months up to 31st March 1883 there were raised, on an average, daily, 15,514,886 gallons of sewage to an average height of 8·78 feet, to be discharged into the outfall. Now, it appears that the total daily water-supply, filtered and unfiltered, amounted at the same time to 9,663,301, hence, making no allowance for evaporation, which, however, is an important exit for water, the amount of sewage raised and discharged by pumping exceeded the total water-supply by 5,851,585 gallons, and to this extent the sewage system of Calcutta afforded daily relief to the low water-logged site it is built on.

20. Works of drainage and water-supply being now in a sufficiently advanced state to enable house improvements to be undertaken, we are glad to see that the municipality is determined to grapple with the all-important, though very difficult, question of *bustee improvement*, because it is in these foul places that the Calcutta epidemics have their origin. Without drainage and water the only remedy against this bustee property was simply clearance of the site, but now that the foundation has been laid many of them will no doubt admit of being improved in construction and in sanitary arrangements.

Up to the end of the official year 1883 there had been carried through the bustee districts 4,969,000 superficial feet of roads, and 19,684,000 superficial feet of ditch surfaces had been drained and converted into paths, making a total improved area of 24,653,000 feet, or 1,714 bighas of 14,400 superficial feet each, and on these facts of drainage work the chairman remarks that, "as there are "only 3,074 bighas of bustees in the whole town, many of which are very small and capable of "surface drainage, it will be easily understood what an enormous revolution in the condition of the "bustees has been silently effected by operations of the Drainage Department. Many bustees have "been so thoroughly reclaimed as to be quite unrecognisable by those who knew them in their "former condition."

There are many cases, however, in which properties have to be wholly or partially removed, and these are often difficult to deal with. The whole subject is, however, in hand, and need not be further dwelt on at present. Time and money are both necessary for the work. One of the worst blocks, Jora Bagan bustee, covering 28 bighas, it was found would cost 34,400*l.* for acquisition, and 7,100*l.* for roads and drainage.

21. But after all, the chief disease causes are distinct from the bustees, although incidental to their existence. These are the foul tanks and local difficulties in the way of cleansing. Years ago, Dr. Payne, then Officer of Health, called attention to the tanks, of which he had measurements made of 795, exposing a foul surface of 146 acres, as prominent disease causes among the bustees. Their contents were chiefly filth and sewage, and many of them were the sources of water-supply for the inhabitants. Up to the end of the official year 1883, 138 of them had been filled up, but the work is proceeding very slowly; and although "the majority of the worst class of tanks has been filled up," there had apparently been no supply of pipe-water laid on for the use of the people whose tank-water had been taken away. Steps, however, had been taken to remedy this deficiency.

22. In the matter of surface cleansing a special establishment had been appointed, "with the best results, from the commencement of 1883–84." In other respects the cleansing was being improved, and this Report for the official year 1882–83 shows increased energy in sanitary operations.

23. We cannot do better than close this review by quoting the skilled technical statement of the officer of health, who says: "New roads have been made, foul drains have been piped and converted into clean pathways, new areas have been provided with sewers, and the houses connected with these, for the removal of house and bath washings, which previously stagnated and stank. Streets have been widened, and facilities provided for the removal of refuse; tanks and wells containing water, which has been truly described as diluted sewage, have been filled up, and substantial progress made in the reclamation of some of the worst *bustees* of the town."

Public opinion had been so far educated on the subject of health improvements that public agitation on behalf of greater vigour had manifested itself on two occasions, on each of which the municipality appointed a committee, the outcome of which has been:—

"(1.) The organisation of a nuisance department.

"(2.) The organisation of an establishment for bustee conservancy.

"(3.) The assignation of more money for bustee improvement and general conservancy."

(4.) Household "rubbish, in place of being cast on the footpaths and roadways, is now retained in bins and baskets, and removed from the interior of compounds by carts.

"(5.) Accelerated effort to increase the water supply of the town."

(6.) Improvement in the sewer system.

This, of course, must include sufficient water for keeping all the drains and sewers free from deposits.

The whole case as regards future progress in the sanitary improvement of the capital of India is fully discussed in the Government Resolution on the Report under review. But the most important of all present work is cleansing and keeping clean. The extension of drainage, water-supply, and bustee and general town improvements will take time, but cleanliness is an ever-present need, which it is also possible always to comply with. Very much remains to be done, and it is in this direction that enlightened public opinion, properly expressed, may do good. Sanitary work has not the characteristics which generally ensure progress in other matters. It claims little scientific *éclat*; it has no glory, either military or civil, attached to it. It must be done solely for the public good, and the public must bear its part of the work and of its cost before it can reap the great benefits which follow in time.

24. Part of these benefits have been already reaped, and, while we are desirous of adding our voice on the side of progress more rapid than has hitherto taken place, we shall conclude the present memorandum with the following passage from Dr. McLeod's lecture already referred to, which gives a brief statement of the results to public health hitherto attained, and by doing so holds out abundant hope in the future. He says: "The time was when people met at the beginning of the cold weather, and congratulated each other on having escaped the perils of the hot weather and the rains. Malarious fevers have been all but banished from the city, the type of many diseases, dysentery, for example, has got milder, and life is more secure than it was. History tells of great plagues in former times; of a famine in 1752 that carried off large numbers; a severe epidemic in 1757; of another in 1762, which killed 50,000 natives and 800 Europeans; of a famine in 1770 that killed 76,000 souls. These terrific visitations have ceased. Sir Ranald Martin, in his work on the influence of tropical climates, gives figures showing the mortality of Calcutta for five years, 1832 to 1836. The rate was 51·7 per 1,000 of inhabitants. The present rate is 30 per mille. A difference of 20 deaths per 1,000 represents in Calcutta an annual saving of 8,664 souls. The case is stronger if we take particular diseases, such as cholera and small-pox. Dr. John Macpherson, in his work on 'Cholera in its Home,' gives the aggregate of cholera deaths in Calcutta for 26 years, ending 1860. The annual mean is 4,911 deaths. The annual mean of the years 1865 to 1869 is 4,388, and of 1870–82, the period of improved drainage and supply of pure water, 1,385. This represents a saving of 3,000 lives yearly, or 40,000 in the 13 years. The total mortality from small-pox in the decade 1873–82 was 3,600, against 6,058 in the previous decade."

The whole case is as complete as it could well be. Amid great difficulties incident to the adoption of totally new sanitary works in a climate differing materially from that of the country in which they took their origin, in the face of much ignorant opposition on theoretical grounds which have no place in sanitary proceedings, and notwithstanding great and unexpected outlay, the Calcutta authorities have persevered, not always without halting, it is true; but a glance at the results already attained ought to be the strongest inducement to perseverance until the capital of India is finally cleansed of its local disease causes.

14th August 1884.

No. 13.

Memorandum of the Army Sanitary Commission on the Administration Report of the Madras Municipality for 1882.

1. It appears from a statement made by the President of the Municipal Commission that the census figures of 1881 had not been used in this Report because the returns had been made by wards and not by villages. The figures of the previous census of 1871 had therefore been used, so that we have no accurate account of the death-rates in the different population groups which make up the city of Madras.

2. The total population given in the tabular abstracts is 397,552. There is a considerable moving population, so that the actual numbers on which the death and birth-rates should be taken are liable to variation. Our estimate of the numbers in 1881, given in our memorandum on the municipal report of that year, was 404,636; but as this number included some houseless poor, it is probable that the ratios remain very much as they were, and that the population total adopted in this year's Report is practically a reliable one, at least that it is not far from the truth.

3. The births, excluding stillborn, were as follow :—

Males	8,599	
Females	7,924	
	16,523	
Stillborn	468	
Total births	16,991	= 42·7 per 1,000 of population.

The registration of births has been improving, for the number registered in 1872 was only 8,166, considerably less than one half of the numbers reported in 1882.

4. The deaths registered in 1882 were below the average. They numbered 14,169, of which 7,108 were males and 7,061 females.

The conjoint death-rate was 35·6 per 1,000, against 38·9 per 1,000 in 1881, and 37·4 per 1,000 in 1880. The average number of deaths registered during the previous 10 years, but excluding the pestilential ratios of the famine time, were 14,946, so that the actual deaths registered in 1882 were 777 below the average.

5. The death-rates among different classes of the population were as follow :—

	Ratios per 1,000.
Europeans	21·3
Eurasians	27·8
Native Christians	24·0
Hindus	37·9
Mahomedans	29·8

The European death-rate is probably kept down by sending away children, and leaving Madras for change.

6. The following were the death causes in 1882 :—

Diseases.	Deaths.
Cholera	461
Small-pox	355
Measles	148
Fevers	3,706
Bowel complaints	2,110
Other diseases	7,389
All causes	14,169

The next abstract gives the deaths from each cause in the villages in Madras for the year 1882.

Villages.	Population.	Cholera.	Small-pox.	Measles.	Fevers.	Bowel Complaints.	All causes per 1,000 of Population.
Tondiarpettah	35,240	13	23	1	104	45	30·6

Thanampettah	7,248	—	12	3	44	24	21·3

7. This abstract shows which are the epidemic points in Madras, or rather the villages in which epidemics prevailed most severely in 1882, and the facts may be taken as in some sense showing where sanitary work is most required. This conclusion is not invalidated by the fact that 804 deaths out of the year's mortality took place in the hospitals, because most of these would be due to diseases arising in the villages which supplied the cases.

8. The present Report, although entering fully into the disease statistics of 1882, gives no information regarding the sanitary state of the villages, or on the conditions affecting the public health. We must, therefore, endeavour to carry back the disease history in order to ascertain the relation of the epidemic facts of 1882 to those of preceding years, and perhaps the best way to do this will be to include in one abstract the deaths from all causes and from cholera and fevers for the following years:—

Years.	Deaths from Cholera.	Deaths from Fevers.	Deaths per 1,000 of Population. All causes.
1870	861	2,296	29·9
1871	493	2,474	32·7
1872	5	2,843	35·2
1873	6	2,569	36·7
1874	—	2,679	36·8
1875	225	2,843	35·5
1876	2,105	2,351	39·6
1877	3,025	6,407	99·9
1878	85	4,982	47·5
1879	35	3,465	34·7
1880	2	3,549	37·4
1881	126	3,698	38·9
1882	461	3,706	35·6

The great mortality of 1877–78 was due to two causes, first, the influx of an unknown number of famine-stricken people, and second, calculating the death-rate on the only approximately known population element, namely the residents. These two years are quite exceptional, but if we leave them out we still have very high death-rates from all causes, especially from fevers, and an increasing loss from diseases of the febrile group. In all the elements of progress the statistics are more unfavourable in Madras than they are in the other two capital cities.

9. The next abstract shows the monthly incidence of deaths from assigned causes in 1882.

Months.	Cholera.	Small-pox.	Measles.	Fevers.	Diarrhœa and Dysentery.	Other Diseases.	Total Deaths.
January - - -	160	14	21	367	254	597	1,413
February - - -	203	34	23	339	229	509	1,337
March - - -	74	62	17	287	141	582	1,163
April - - -	20	56	16	251	120	554	1,017
May - - -	4	32	20	268	151	590	1,066
June - - -	—	27	15	287	123	565	1,018
July - - -	—	30	5	288	160	612	1,095
August - - -	—	20	6	359	236	657	1,258
September - - -	—	50	4	346	184	623	1,187
October - - -	—	21	8	285	179	665	1,158
November - - -	—	18	5	279	150	684	1,131
December - - -	—	15	8	369	183	751	1,326

The cholera mortality in this table shows apparently the passing over of an epidemic outbreak from the previous year. In a preceding abstract we have shown the incidence of cholera among the population groups, and that 27 of these groups out of 36 yielded cholera deaths. The previous year's cholera deaths, which were 126 in number, all took place in 12 population groups towards the end of the year, and then, as now, the Madras Report gave no information on the local causes. These 126 deaths were made up of 1 in September, 2 in October, 40 in November, and 83 in December.

The President of the Municipal Commission makes the remark that this cholera epidemic of 1881–82 "fell most heavily on those parts of the town that were dependent on wells for their water-"supply, and were beyond the distribution of the Red Hill water pipes; 333 deaths, or 57 per cent., "occurred in these localities, namely, Royapooram and to the north of it, and St. Thomé, with a "population of 86,000, or one-fifth of the whole of Madras, while 254 deaths occurred in the rest of "the city, with a population of 320,000."

This observation is a very important one, resting as it does on statistical fact and not on opinion, and it points not only to the effect of foul drinking water in aggravating epidemics of cholera when they happen to be in a district, but to the predisposing influence of subsoil conditions, with or without the foul water addition. Cholera prevailed where the drinking water was comparatively pure, but not to the same extent as where the influence of foul water was added to the influence of foul subsoil. In this region the death-rate from cholera was nearly fivefold what it was in the purer water districts, but still cholera was there, and we have referred to some evidence supplied by cholera among convicts in our memorandum on the Sanitary Commissioners' Report on Madras Presidency for 1882, which leads us back to the unwholesome subsoil conditions of this city to which we have often referred in previous memoranda.

It is unnecessary to dwell further on the disease history of the year. We can only express the regret that the Madras Report has not been arranged like those for the other cities, which not only give a good general idea of the year's disease causes, but point to the remedies at the same time.

10. *Sanitary measures.*—By far the most satisfactory part of the year's work comes under the designation of conservancy. The amount spent on this important sanitary measure was 24,669*l.*, and 1,219 coolies, 621 carts, and 5 canal barges were employed in the removal of 404,000 cartloads of rubbish and filth, besides 10,530 tons of night-soil. Part of the sewage is applied to seven sewage farms, of which the receipts and expenses are given for six. Three of these yielded a profit in working of about Rs. 1,500, and three others a loss of Rs. 2,100. The remaining one appears to ave been only commenced by an outlay of Rs. 241.

11. *Water-supply.*—The Red Hill works appear to be still in an unsatisfactory state. "Fish ten inches long have been found jammed up in two-inch pipes." It is quite truly said by the president that this state of matters must continue until filtration is introduced. In the course of the year a loan of 25,000*l.* was contracted for extending the present water-supply by pipes, and in three of the city divisions "17 miles of pipes were laid, varying from one to six inches in diameter, 124 valves, and 211 hydrants were fixed, and 133 fountains were erected," besides one in front of the General Hospital. All this is a real advance on the past state of matters, but it is to be regretted that some of the worst epidemic localities cannot yet be brought under this improvement. We have little doubt, however, that good results to the public health will follow this water expenditure.

12. We have so often discussed the sewage principles which have been adopted for Madras, that it is unnecessary to enter further on the subject. We can only wait the results, and express a sincere wish that they may be better than we have been led to anticipate from similar works in other Indian towns. Among drainage works still in progress was diversion of sewage from the Cooum and canal. The necessary intercepting sewers had been laid, and a pumping engine and well were in course of completion.

13. Since the date of the Report under review Madras has been visited by a severe epidemic of small-pox, and the only fact bearing on this matter is, that in 1882 the vaccinations under one year of age were 8,968, or about half the children born. It is evident that increased activity in this branch of sanitary work is needed.

14. In conclusion, the present Report, although containing very full statistics of village death-rates and their causes, is deficient in sanitary details, so that the relation of deaths to local causes has rather to be guessed at than proved. The all-important conservancy work appears to be increasing in extent and efficiency, and in the present state of the subsoil this means of disease prevention has mainly to be relied on for protecting the public health.

An important extension has been given to the existing water-supply, which we hope will have a beneficial effect on the health of the villages where it has been introduced. But it seems to be a corollary to this work that the bad wells should be filled up.

One of the most important drainage measures has been the diversion of sewage from the Cooum and canal.

Lastly. It is evident that the vaccination service requires extension, so as to cover the births, and, even when this is done, it will take years to reduce small-pox mortality to its lowest attainable point.

3rd September 1884.

No. 14.

MEMORANDUM of the ARMY SANITARY COMMISSION on the ADMINISTRATION REPORT of the MUNICIPAL COMMISSIONER of BOMBAY for 1882.

1. The population of Bombay, according to the census of 1881, was 773,196. The births were, of—

Males	-	7,945
Females	-	7,421
Total	-	15,366 = 19·87 per 1,000 of the population.

The deaths in 1882 were, of—

Males	- 10,861
Females	- 9,607

The male death-rate was 23·36 per 1,000, and the female death-rate 31·14 per 1,000.

The total deaths were 20,468, or 25·89 per 1,000, calculated on the census population, *plus* a year's increment.

It seems likely from these facts that registration of births is still defective, otherwise we should have to accept them as showing that the population of Bombay is kept up by immigration. There is, of course, the usual difficulty which shows itself, in the case of seaport towns, that there is a large shifting population both by land and water. Whatever be the explanation, the birth-rate cannot be accepted as correct.

2. The following abstract gives the population and death-rates according to classes:—

Classes.	Population, 1881.	Deaths per 1,000.
Jains -	17,218	53·08
Brahmins -	35,423	21·02
Lingaets -	1,167	35·13
Bhatias -	9,417	29·62
Hindus of other castes	407,717	24·99
Hindu low castes -	49,122	32·14
Mussulmans -	158,024	29·87
Parsees -	48,587	18·48
Jews -	3,321	24·08
Native Christians -	30,708	23·05
Eurasians -	1,168	31·67
Europeans -	10,451	17·70
Negro Africans -	689	194·81
Chinese -	169	11·83
Others -	—	?

3. There is a difficulty in estimating the death-rates of Bombay for a series of years on account of the population element, which is not easily arrived at; but the following registered mortality for the

last six years shows that, with a rapidly increasing population, the annual deaths registered have been undergoing a continuous reduction:—

Years.	Total Deaths in the City.
1877	33,511
1878	26,999
1879	22,527
1880	21,146
1881	21,856
1882	20,468

4. The next abstract gives the deaths and death-rates arranged under their assigned causes on the calculated population of 1882.

Causes of Death.	Number of Deaths.	Deaths per 1,000 of Population.
Small-pox	92	0·11
Measles	991	1·26
Fevers	5,453	6·90
Cholera	192	0·24
Phthisis	2,729	3·45
Nervous system	2,557	3·24
Respiratory diseases	3,402	4·30
Diarrhœa	1,093	1·38
Dysentery	525	0·66
Accidents	346	0·44
All other causes except still-born	3,088	3·91
Total	20,468	25·89

5. As usually happens, the total death-rates and the rates from particular diseases vary considerably in different districts of the city, and, perhaps, the best general idea of the sanitary condition of Bombay in 1882 will be found in placing the ratios for each district under one view, including the rates from epidemic diseases, together with the general death-rate.

Localities.	Population, 1881.	Death-rates per 1,000, 1882.				
		Cholera.	Small-pox.	Fevers.	Measles.	All Causes.
Colaba, Upper	2,867	1·04	—	5·58	—	27·90
Colaba, Middle	14,265	·49	—	5·53	1·33	18·78
Colaba, Lower

Sewree	5,556	·54	—	8·10	0·54	22·32
Sco	17,237	·11	·05	8·35	0·23	21·81
Mahim	17,309	—	—	9·59	0·17	22·47
Worlee	14,621	—	—	9·37	0·13	19·62
Water division	24,887	·60	—	1·36	—	3·41

6. These tabular statements give the year's sanitary history in sufficient detail for practical consideration, and the first point which attracts attention is the insignificant death-rate from cholera, and yet, on account of this one disease, the European Powers keep up a costly and, so far as

commerce is concerned, a vexatious quarantine establishment. By the same process of reasoning, through which the contagiousness of cholera is believed in, there are many who hold the contagiousness of phthisis, and the prevailing view is that both possess a particulate contagion of the same genus of fungi. Now, the mortality from phthisis in Bombay in 1882 was 14 times the mortality from cholera, and the mortality from fever 28 times the mortality from cholera. Even measles yielded fivefold the mortality of cholera, yet cholera is the only one against which quarantine is considered necessary. It seems impossible to escape the conclusion that reasoning on the quarantine hypothesis demands the stoppage of all intercourse between Bombay and the West. This much on the general subject, and although, in the present state of public intelligence on health questions, no one would dare to apply the results in actual practice, it is necessary to re-state the facts by way of caution, and to show in what direction the real logic of them would carry us.

7. The amount of cholera in Bombay in 1882 was not so great at any one time as to call for much discussion, but the following statement by the Officer of Health may be quoted as indicating generally the local sanitary state of affected localities: "The conditions amidst which groups of cases arose, "were generally those conditions observed surrounding outbreaks of 1881; there has been a distinct "intensity manifested in particular districts and around particular centres of population, but the "incidence of the mortality from cholera and of the total mortality have not fallen uniformly and "with uniform severity throughout the districts of the city; sections of the highest total mortality "are not sections of the highest cholera mortality. The chief predisposing influence appeared to be "of an individual constitutional nature, so to speak. The most general conditions I observed "surrounding the groups of cholera cases were, as in 1881, shortly, dampness, dampness of ground, "of walls, imperfect ventilation and resulting air impurities; the exciting agencies of greatest "potency, inasmuch as of most frequent occurrence, appeared to be dampness, humidity, which "implies soil saturation, and pollution, arising from imperfect channels for removal of sewage, "sewage stagnation and soil saturation and pollution being in the relation of cause and effect, air "impurity and darkness arising from defective ventilation and lighting, dwelling and surface "crowding."

8. We have here the local conditions described which specially characterise epidemic localities, and there is a fact stated about the incidence of cholera in Bombay which appears to show clearly the dangers of coming fresh into such places, for it appears that out of 236 cases and 192 deaths from cholera in 1882, only 21 cases and 17 deaths took place among persons born in Bombay; all the rest, with the exception of three cases and two deaths not traced, occurred among immigrants.

9. In former years we have quoted the facts regarding relation of cholera to water sources as a contribution to the disputed question of the causative effect of bad water on cholera mortality, which last is still a favoured theory with some people. We shall again quote the experience of 1882.

—	Cholera Cases.	Deaths.
Vehar or Tulsi water consumers	165	135
Well water consumers	37	32
Not known consumers	34	25

These facts give the history of cholera in 1882, in relation to the water sources. And it will be seen that the weight of the epidemic of 1882 did not fall on those who used the sewage-polluted wells, but on the population supplied with water brought from country gathering grounds by pipes. The quality of the pipe water is not all that could be desired, or that it will be when the works are completed, but it is greatly improved over the old well supply. The real reason of the higher cholera rates with the outside water-supply is its extension to epidemic localities which yielded by themselves, and apart from the water, the higher cholera rates.

10. The sanitary precautions adopted during the cholera of 1882 aimed at "cleanliness in the "widest sense, so far as practicabilities, the more cleanliness, the more perfect prevention, experience "in combating disease in this city indicates."

Facilities for constant cleanliness, and keeping clean, are the ends aimed at by all sanitary engineering works, and the benefits of the public health already obtained in Bombay may be estimated in some measure from the fact that 1882 was a great epidemic year in India, during which 347,932 people died of cholera. Of these 7,904 died in Bombay Presidency in scattered villages over a great extent of country. The Presidency death-rate was 0·48 per 1,000, whilst the city death-rate among an overcrowded population of 773,196 was 0·24 per 1,000, or just one-half the Presidency rate, and, as we have already shown, the total deaths from cholera among known Bombay people were only 17 out of 192, the remainder, so far as is known, having been among immigrants. We shall conclude this notice of cholera with the following monthly deaths in 1882:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	82	July	12
February	52	August	12
March	17	September	6
April	5	October	2
May	1	November	—
June	—	December	1

The cholera history of Bombay is very different now from what it was in old times, when its deaths were numbered by thousands, as we have shown in other memoranda.

11. *Fevers.*—These were the most important death causes in 1882, and it may be useful to extract the year's registered fever deaths arranged according to the nomenclature of the Royal College of Physicians, for in this way we shall obtain a better account of the causes:—

Fevers.	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Total Deaths.
Enteric	—	3	2	1	1	1	3	—	6	1	2	2	22
Relapsing	—	—	—	—	—	—	1	—	—	—	—	—	1
Simple continued	58	58	73	65	94	79	59	94	105	80	75	87	927
Ague	30	19	18	14	13	10	26	18	22	25	21	27	243
Ague, with bronchitis	2	1	1	—	—	—	—	—	—	—	—	—	4
Ague, quotidian	7	1	5	22	11	3	—	6	2	7	2	1	67
Ague, tertian	—	—	—	2	—	—	—	—	—	—	—	—	2
Remittent	454	425	473	305	309	248	267	305	332	358	328	291	4,095
Remittent, with bronchitis	10	3	1	1	1	2	—	1	2	5	3	6	35

Remittent, jaundice	1	—	1	—	1	—	—	—	1	—	—	—	4
Remittent, pneumonia	—	1	3	—	2	1	—	—	2	—	—	1	10
Cerebro-spinal fever	—	—	—	—	1	—	—	—	—	—	—	—	1
Total monthly fever deaths	587	518	581	476	433	344	357	424	472	480	431	418	5,455

Arranged in this manner, with their fatal complications, we see at once that ordinary malarious fevers are not frequent as death causes in Bombay. The whole ague tribe, with their complications, gave rise to only 316 deaths, or under 6 per cent. of the total fever mortality. The deadly fevers were remittents and continued fevers, which gave rise to 94 per cent. of the fever mortality. There were only 22 deaths attributed to enteric fever, one to relapsing, and one to cerebro-spinal fever.

Sanitary work has thus to deal not so much with the ordinary malarial fever causes, but with that class of causes which in tropical cities and towns give rise to fatal continued and remittent fevers, and these are all more or less co-existent everywhere with putrescence. It follows that the general improvements in drainage, water-supply, cleansing, paving, and house improvements now in progress will afford the best security against fevers in Bombay, as in other cities. There is evidence of progress in these matters in the statistics, which show that ever since 1848 there have been very few years, only six, in which the registered fever death-rate has been a shade lower than in 1882. In all the others it has been considerably higher, and in certain years the deaths have been those of pestilences, as for instance in 1864-65, when 31,360 people died, and the famine year, 1877, when the fever deaths amounted to 12,832. The statistics, as a whole, show the presence of what may be called a certain fever tension ready to pass its bounds on occasion, and the result is, as already stated, that sanitary work should be vigorously pressed forwards. This view is further sustained by the facts shown in the preceding table, that fever death-rates in Bombay are not subject to climatic influence as they are elsewhere, proving in another way that their causes are more or less purely local, as is also shown by the diversity of rates in different localities of Bombay given in a preceding table.

12. We may go a little further, and cite a case or two of local fever outbreaks. One of these was in an educational institution in an open situation where enteric fever broke out.

It had no house drainage, and the sewage could not be properly dealt with for want of it. "In "the privies," we are told, "in this institution there was not the great safety against putrid organic "exhalation which exists in privies in the town, which is this, place for reception of fæcal matter "exposed to light and air, but there was sufficient ventilation to excite changes not sufficient to "destroy the products of change." Of course the only comment that can be made on such a state of matters is, that there ought to be no sewage there at all, and that it is the duty of the municipality to provide for its immediate removal by drainage and water. Take another example, where relapsing fever cases took place among poor Mecca pilgrims in a "chall," now removed on account of its unhealthiness. The Officer of Health reports of it as follows:—"Ground on three sides a swamp, "to enter rooms on ground floor must wade through swamp, rooms on ground floor had each a "separate door giving a separate entrance and opening on to the swamp." This brief note tells us the state of the subsoil and the cause of the fever in half-starved people.

Fever mortality yielded a death-rate of 6·46 per 1,000 males, and 7·93 per 1,000 females. The most fatal ages for fevers are those under three years and above 50 years of age, when the death-rates taken on the population of these ages are the highest. The rates to population are all very much lower for the intervening ages, but inasmuch as these ages include the great mass of the population, fever death-rates as usual tell most severely on the productive ages, and tend directly to impoverish the people.

As regards locality, it has been shown in a preceding table that fever death-rates vary greatly in different parts of the city, between 1·13 per 1,000 in Fort Southern and 12·71 per 1,000 in Parell; there must be causes to yield such diverse rates.

13. *Small-pox.*—The last epidemic outbreak of small-pox in Bombay took place in the year 1876, when 3,174 deaths from this cause were registered. Since this event the deaths have been as follow:—

Years.	Small-pox Deaths.
1877	958
1878	357
1879	479
1880	207
1881	35
1882	92

The deaths in 1881 were the fewest recorded in any single year. Bombay has an active vaccination service, and calf lymph has been in use. As we have already seen, the year's births amounted to 15,366, a number below the truth apparently. The vaccination work of the same year stood as follows:—

	Successful Vaccinations.
Under one year	12,619
Under six years	3,837
Above six years	587
Total successful	17,043

These data show a great amount of good vaccination work done at the younger ages, when it is most useful. Besides these primary operations there were 973 successful re-vaccinations, raising the total successful cases to 18,016. These facts are sufficient to give a general idea of the year's disease history, and we shall next say a few words on the sanitary work done.

14. *Sewerage and Drainage.*—The works in progress during the official year 1882–83 were the first portion of the new sewerage works, including the new main sewer from Love Grove pumping station to Carnac Bunder, the outfall sewer at Worlee, laying of pipe sewers, the pumping station at Love Grove; and of details of work, the Queen's Road intercepting sewer, sewerage of Kamatheepoora, and the surface draining scheme. The works appear to have made considerable progress during the year, and there are some points of experience which have been obtained from their execution that throw light on local disease causes. The following quotation from the Engineer's report shows the effect of laying drains on the subsoil water level:—

"It may be incidentally observed that the laying of the pipe sewers in connexion with the main sewer has had a very marked effect in lowering the subsoil water of the districts through which they pass. Where pipes were laid under the greatest difficulty, owing to the large quantity of water, the ground on subsequent re-opening has been found comparatively dry. The subsoil water was undoubtedly in numerous places confined in pot holes or depressions in impervious trap, and, the rims of these depressions having been cut through for the pipes, a creep of water has taken place along the filling of the trenches, all of which have a fall to the main sewer, which itself has, of course, a fall throughout its entire length."

This passage points to a not uncommon fever cause in India and at military stations, and it also describes the remedy, which in the present case was applied without any cost to the rates in the process of ordinary pipe drainage. In draining houses the same results are obtained. Sewage is removed and subsoil water at the same time, and the subsoil is dried and purified.

15. The other case is even a more remarkable example of how neglect of house drainage fouls the whole subsoil. It is the case of Kamatheepoora, which had a death-rate of 38·76 per 1,000 in 1882. Attempts had been formerly made to drain this district, but the works were defective, and it was resolved to redrain it, and the following experience was obtained.

All the trunk sewers having been finished, the laying of house branches was commenced in the sweepers' passages.

"The work was foul to the last degree, the walls of the houses on either side being besmeared with night-soil, and filth of all kinds" trickled down the walls on to the paving, "dirty and greasy "water coursing down the wall from holes communicating with nahanis and cookhouses, and the "soil saturated with sewage from defects in the paving and the work of rats about it. So disgusting "was the work to be done that the contractors found the greatest difficulty in obtaining workmen "to do it." The difficulties were so great, partly from the construction of the houses, that the contractors were ordered to excavate only four feet, and in some cases only two feet at a time, and to lay the pipes and fill in the excavation as the work proceeded. Unfortunately, the new house fittings could not be put up in connexion with the new drainage, so that matters remained much in the same state. One house, however, had the new privies put up and connected with the drains.

"The privies act exceedingly well, and are so much approved that the people in large numbers from the surrounding neighbourhood use them in preference to their own." They are trapped and supplied with water, and "the occupiers of the houses state that they never perceive any smell." The municipal stables and others have been connected with the drains, "and are in perfect action."

It is to be hoped, with this experience before them of the neglect of drainage in times past and its results to the public health, and also of the applied remedy, we shall hear no more of the inapplicability of Western engineering works to Eastern habits of life.

16. There is a surface drainage scheme under contract for relieving the sewers of excessive rainfall, and one part of it appears to be the formation of a storm-water reservoir, having an area of 176 acres. We can say nothing about this proposed work except to suggest that there should be as little evaporating margin in the dry weather as possible. An area of 176 acres of clean rain water would be of no injury to air purity. It would be otherwise if the water were mixed with sewage, but positive injury to health might result if a large area of impure water, or of the bed it covers, were left to evaporate under the sun after the bulk of it had been drawn off by the drains.

On the whole, it is very satisfactory to observe that, before long, Bombay will have its house drainage in the way of execution.

17. *Water-supply.*—The rainfall over the Vehar and Tulsi gathering grounds was considerably below the average in 1882, as is shown in the following table :—

Years.	Vehar.	Tulsi.
	Inches.	Inches.
1879	76·42	99·62
1880	72·42	98·76
1881	59·10	86·14
1882	54·63	74·22

There is a cycle of diminished rainfall in progress, and as a natural consequence the residual lake water increases in impurity. This has been especially the case with the Tulsi water, and was formerly the case with Vehar water. Time and increase of rain will diminish the impurity, but, as this is mainly of vegetable origin, it is more disagreeable than injurious. The great remedy, however, is filtration at the point where the supply is passed for distribution into the pipes. The present sources of public supply are 46 dipping wells, the worst of all methods, 54 drinking fountains, 24 stand pipes, 13 large ornamental fountains, 12 cattle troughs, and 13,244 house connexions. This last method of supply is making steady progress. There are 737 water meters in use.

There were 4,241 notices of leaks served and repairs to be executed. Mains and house services were inspected by the waste prevention establishment, which since it began operations had discovered a waste of 437,000 gallons of water per diem.

The Malabar hill reservoir works were still under construction.

It may be stated, in connexion with the water supply of Bombay, that the Parsee community have erected a large ornamental drinking fountain to commemorate the late Mr. Bomanjee Hormarjee, one of their heads. It is in the ancient Persian style of architecture, 2,500 years old, and the cuneiform writings on it have been selected from copies of a rock inscription in Behistun of the same period. The work was done by the engineer, Mr. Walton.

18. During the year under review the Conservancy Department has been actively engaged in cleansing operations. The average cleansing staff consisted of 2,643 men and women. There were 463 scavenging and drain-cleaning carts, and 103 night-soil and cesspool carts in daily use. By this agency 141,611 tons of garbage were removed in the course of the year, against 136,867 in 1881, and the daily removal of night-soil was 2622 tons, against 2336 tons in 1881.

Cleaning out of covered drains is still necessarily carried on, and 205¼ miles were dealt with in this way in 1882.

19. These are the chief points in the present Report which appear worthy of note. There has been no great public work done, but what is more to the purpose, there appears to have been steady progress made in useful sanitary detail, especially in cleansing, which is the great element to depend on for warding off the invasion of epidemic diseases. This can always be done, more or less completely, by hand labour, until the completion of house and street drainage in connexion with the water-supply enables the house sewage to be disposed of at the outlet.

6th September 1884.

No. 15.

MEMORANDUM of the ARMY SANITARY COMMISSION on PAPERS referring to the SANITARY CONDITION of the MADRAS EUROPEAN ARMY, and to the prevalence of ENTERIC FEVER among the TROOPS.

These papers, although not all included in the same reference, refer to the same subject, and we propose to consider them together in the following remarks:—

1. The average strength of European troops serving at Madras stations in 1882 was 10,817 non-commissioned officers and men. There were 11,546 admissions to hospital, 114 deaths, and 321 men were invalided for change or discharge.

These numbers yield the following ratios per 1,000 strength;—

	Ratios per 1,000.
Admissions	1,069·06
Deaths	10·54
Invalided	29·67
Daily sick	64·25

Admission and death-rates were under those of the preceding year. The daily sick and invaliding rates were a shade higher. When the rates are compared with those of the previous ten years they yield the following differences:—

	Ratio per 1,000.	
	1872–81.	1882.
Admissions	1,225·63	1,069·06
Deaths	15·63	10·54
Invalids	41·13	29·67

These figures show a considerable improvement in the sanitary state of the Madras army during the year 1882, and if it continues without material increase of sickness in subsequent years, the statement made by the Surgeon-General, "That it may be safely said, therefore, that the constant "attention which has for years been devoted to the sanitation of military buildings and to everything "likely to improve the health of the European force in this command has been productive of good "results," will become an established truth. That there is evidence of much improvement in the statistical facts may be safely admitted, but Madras is subject to sudden increase of epidemics, which also affect the troops; and while admitting the evidence of improvement, it is better to take it simply as an instalment of what may yet be accomplished by the complete application of sanitary principles and methods of procedure at the stations and in their vicinity.

2. We shall next give a brief account of the chief diseases of the year, beginning with the most fatal of them, enteric fever, from which there were 47 admissions and 23 deaths.

The following table given in Surgeon-General Madden's Report shows the stations at which enteric fever prevailed in 1882. We have added the strengths from Dr. Stephens' tables:—

Stations.	Strength.	Enteric Fever.	
		Cases.	Deaths.
Madras	739	2	2
St. Thomas' Mount	380	3	2
Cannanore	716	1	—
Calicut	101	1	—
Bangalore	1,717	19	7
Bellary	952	6	2
Wellington	556	3	2
Secunderabad	2,558	8	6
Kamptee	866	1	1
Rangoon	705	2	—
Thyetmyo	688	1	1
Total	9,978	47	23

The ratio of attacks for all the stations which yielded cases was a shade over 4·7 per 1,000, and of deaths 2·3 per 1,000.

3. This table shows a very general distribution of enteric fever throughout the command, although the actual death-rate was highest at Bangalore.

4. The next abstract shows the relation of enteric fever to age of troops.

Ages.	Cases.	Deaths.	Ratio of Admissions per 1,000 of Men of ages specified.
Under 20	3	3	11·40
20 to 24	34	15	8·52
25 to 29	10	5	2·84

The predisposing influence of young ages is clearly shown in this table. At 25 and above there is little risk from enteric fever. The chief danger is past by that time.

5. The influence of service years on the amount of fever was as follows:—

Service in India.	Admissions.	Deaths.
Under 1 year	15	5
1 to 2	11	9
2 to 3	7	3
3 to 4	6	3
4 to 5	3	2
5 to 6	4	0
8 to 9	1	1

These two abstracts merely repeat the well-known fact that young ages and early years of service determine the liability of the European army in India to attacks of this fatal fever.

A singular exception to the rule holds in the case of women and children, who suffer little from this disease. There were 851 soldiers' wives and 1,466 children at the stations. There were two cases of enteric fever among women and three among children, but none of them died. The liability of different classes is shown as follows:—

	Officers.	Non-Commissioned Officers and Men.	Women.	Children.
Enteric fever admissions per 1,000 strength	12·74	4·34	2·35	2·04
Ditto deaths per 1,000	3·18	2·12	—	—

6. In following up the history of enteric fever, we shall in the next abstract show its relation to the general fever history of Madras for a period of ten years preceding 1882, and its annual prevalence during the same years.

Years.	Strength.	All Fevers.		Enteric Fever.	
		Cases.	Deaths.	Cases.	Deaths.
1872	11,511	2,980	34	79	26
1873	11,508	2,672	17	52	10
1874	11,578	2,108	12	34	12
1875	11,233	2,177	11	23	7
1876	11,139	2,176	26	55	23
1877	11,016	2,279	24	65	22
1878	10,880	3,708	25	7	5
1879	10,507	4,175	24	12	10
1880	10,280	4,682	16	25	11
1881	10,389	2,905	8	2	5
Total 10 years		29,812	197	357	129
1882	10,817	1,928	26	47	28

This table shows that the proportion of enteric fever to all fevers, and also its annual ratio of prevalence have varied greatly in different years, and that both are independent of the actual amount of fever in individual years. In one or two of the years the relations of fever types to each other were disturbed by discussions on the nature of enteric fever, but if we admit the accuracy of the diagnosis in all these years, they go to show the independent existence of enteric fever, although it does not follow from this view that many enteric fever cases did not present themselves in the first instance as cases of ordinary climatic fever, or that cases of ordinary climatic fever did not end fatally and yield the *post-mortem* appearances of enteric fever. The eleven years given in the table

show that out of 31,740 fever admissions, 404 were at one period or other of their course diagnosed as enteric fever, or a little over 1·2 per cent. of the whole. The death-ratios, however, had a very different relation; all fevers yielded 223 deaths, but of this number 152 presented the *post-mortem* appearances of enteric fever, or above 68 per cent. of the whole.

The extent of fever prevalence differs in different years, and there are years in the table during which fevers prevailed epidemically, but it was not during these fever epidemic years that enteric fever was of most frequent occurrence. The year 1882 presented the lowest fever admission-rate on record, but with a single exception, this year was the most fatal enteric fever year of the whole series. The number of attacks and deaths was too small to admit of collation with the year's climatic data.

7. There is nothing new in the Report bearing on the question of local causes, but some long-known defects in sanitary condition reappear in it and may be noticed. For example, as has been already shown, Bangalore, out of a strength of 1,717, yielded 19 cases and 7 deaths from enteric fever, and the following remarks on the water-supply are made by the Deputy Surgeon-General:—"The nature of the water-supply at Bangalore might possibly account for the existence of the "disease at that station, were it not that all the troops drink the same water, and but few "comparatively are attacked." This is true, but it applies to all common disease causes. Natural temperament and predisposition enter into the chain of events as well as what are called "causes." Again, "although the native population and troops also derive their water-supply from the same source, enteric fever amongst them is not a frequent disease." But this fact may be nothing more than an illustration in point, for the comparative exemption from this fever of the native population is known to exist all over India. On the subject of climate the Deputy Surgeon-General says "that enteric fever may be modified somewhat by climate is not unlikely, but that it is in any "way of climatic origin there is, to my mind, no proof whatever. I cannot but think that the spread "of the disease is due to articles of food or drink obtained in the native bazaars, or perhaps the "milk brought to the barracks, which has been diluted with water from some contaminated source."

Here again we are meet with the same difficulty, that while all are exposed to the same risks in bazaars, only very few suffer; and as regards milk, the women and children, who are the milk-drinkers, suffer least from enteric fever. All this only shows how difficult a study etiology is, and how little any general assumption or presumed specific cause has helped us hitherto in unravelling the web.

8. Secunderabad yielded eight cases of enteric fever and six deaths out of 2,558 men. On this outbreak the deputy surgeon-general states that "nothing satisfactory could be discovered "regarding the origin of the disease in any of the cases that occurred among the European troops, "but, from the care and attention bestowed on all the sanitary matters affecting the health of the "force, and the absence of any insanitary surroundings in the barracks or their vicinity, it is probable "that the germs of the disease are imbibed by the soldier in the foul air or foul water of an Indian "bazaar."

One of the fundamental principles of station improvement in India is that this includes not only barracks, but bazaars and villages or towns near the station. It is not necessary to seek for special disease germs in these places. What is really wanted is, that the sanitary problem should always be taken to include not only the places where the soldier lives, but the places to which he resorts. It is impossible to predict which man may imbibe the elements of disease in the foul air or foul water of a bazaar, or native town or village, but experience has shown us that some will suffer, and it is hence in the interest of all that the cleansing, draining, water-supply, drinks, foods, &c. of these places should be looked into.

Surgeon-General Madden himself tells us, while referring to the stations, "that in no single "instance was a case of enteric fever amongst the troops traced to any special sanitary defect, "although every effort was made to discover some probable local cause." He, nevertheless, advises that unremitting attention should be paid to the current sanitary condition of the barracks, hospital, food, water, &c. But what of the bazaars and native towns? Of course, without local inspection and inquiry it would be impossible to agree or disagree with the Surgeon-General's estimate, but we have been struck by the fact that two Deputy Surgeons-General at Bangalore and Secunderabad have both called attention to the probable effects of the bazaars on the health of the troops. There is, besides, at Bangalore, the old evil of Ulsoor tank water to be got rid of; and lastly, if there be any relation of enteric fever to the general fever history of India, it can lead to but one conclusion as regards local causation, and this is that station drainage, which has yet to be done, will lessen materially the amount of malarial fever, and in doing so will diminish, in all probability, the prevalence of enteric fever.

9. *Cholera.*—There were 15 cases and 9 deaths from cholera among Madras troops in 1882, but to avoid erroneous conclusions as to the actual facts, it is necessary to go a little further, and by doing so we find that Madras stations yielded only three cases, all fatal; two at Secunderabad and one at Bellary. Of stations in Burmah, Rangoon yielded three cases and one death, and Toungoo had one case, not fatal.

Cholera was epidemic in the course of the year in the Central Provinces, and it appeared among troops marching from Kamptee to Secunderabad and Bangalore, among whom there were eight cases and five deaths. It seems probable that the predisposition was contracted in the Central Provinces, as there was very little cholera in the districts through which the troops passed, except in Berar.

10. *Venereal diseases.*—We have so frequently discussed this subject and its difficulties that little remains to be said about it, but there are one or two points mentioned by the Surgeon-General

which are of importance in the history. He says, "The incidence of venereal disease varies very "much in different parts of the Presidency and in Burmah, as may be seen from the following "table:—

	Ratio per mille of Admissions to average Strength.	
	Syphilis, Primary.	Gonorrhœa.
Eastern district - - - -	143·11	145·42
Western - - - -	74·03	62·98
Bangalore Division - - -	200·68	127·38
Hyderabad subsidiary force - -	55·10	150·73
Nagpore force - - - -	22·75	104·19
British Burmah division - - -	102·17	56·64
Depôts - - - - -	75·04	62·05
On the march - - - -	110·05	43·06

The facts in this table are similar to those which have been supplied by other districts in India, and they show that disease sources or predisposition, or probably both, exist in different degrees of intensity. On the subject as a whole the Surgeon-General makes the following remarks:—

"Lock hospitals have been for years established in all towns occupied by European troops, but "the 'Contagious Diseases Act' is never thoroughly carried out; indeed it would be impossible to "do so in such towns as Madras, Bangalore, or Secunderabad, where a large number of coolie "women can never earn more than one anna and a half, about three halfpence a day, at labour. "The soldier, as a rule, does not restrict his favours to the women who are examined periodically "under the 'Contagious Diseases Act,' and is never likely to do so, as long as there are so many "others available." And then follows this important statement, which shows that fresh sources of infection exist everywhere, whatever diligence may be bestowed in giving effect to the Acts:— "Syphilis and gonorrhœa are diseases extremely prevalent amongst the populations of the towns "of Southern India. The lower classes of natives attach little importance to gonorrhœa, and no "disgrace to those suffering from either complaint." Under such a moral condition of the people, any attempt to cover the whole sources of infection by lock hospitals would be impossible on the ground of expense, but possibly the extension of dispensary relief might to some extent mitigate the evil. Any way, the facts stated by the Surgeon-General appear to account for the failure of the lock hospital system so far as troops are concerned.

11. *Sanitary condition of stations.*—There are a few points under this head that are worthy of notice. It is evident from the statistics that much good sanitary work has been done at many of the stations, especially as regards buildings, and that there is every disposition to continue the work generally. Indeed, the matters recommended for improvement were under consideration at the time, but there are certain of them which we are desirous of sustaining from our knowledge of the facts, as well as from what is stated in the present Report.

The Surgeon-General states as follows, under the head of "drainage and sewerage and general "sanitary condition of barracks." "Though much care, labour, and money have been expended "on improving the surroundings of the barracks throughout the Presidency, still there is much to be "done in this respect. The barracks themselves, and the several buildings connected with them, "are kept in as good order as possible. The main faults are due to their situations." Some important instances of this last preposition may be quoted. Deputy Surgeon-General Murray points out that the Ulsoor barracks in Bangalore are "in very close proximity to the thickly-inhabited "suburb of Ulsoor, the sanitary arrangements of which are by no means perfect." He also considers "the drainage around the barracks at Bellary defective."

Deputy Surgeon-General Colvin Smith, C.B., calls attention to the unsatisfactory state of the ground in the vicinity of the 2nd British Infantry barracks in Secunderabad. The Adjutant-General replies to this complaint that it cannot at present be obviated, as the ground is the property of city nobles. On this subject we formerly suggested that some negotiations might possibly lead to its improvement.

12. *Ulsoor tank water.*—The only remark which appears to be called for, arises naturally out of the following statement of facts by the Deputy-Surgeon General, "in the immediate neighbourhood "of the cavalry and artillery barracks at Bangalore, where the ground is much cut up by *nullahs* "and small watercourses, which are habitually resorted to by the natives for purposes of nature, the "filthy accumulation formed during the dry weather is washed by the first heavy rain directly into "the different tanks to which they respectively lead. As the Ulsoor tank, from which the greater "part of the water for drinking and cooking purposes is derived, is subject to the like contaminations, "as well as that arising from the surface drainage from a thickly inhabited part of the cantonment "of Bangalore, it must have the effect of polluting its contents, and rendering it objectionable, if "not absolutely unwholesome." The probable effect of this fouled water on the extent to which enteric fever prevailed in 1882 has been already alluded to, and it has been shown that out of 47 cases and 23 deaths from this fever, Bangalore had yielded 19 cases and 7 deaths. We are desirous that these facts should not be forgotten until the water-supply for this important station, now under consideration, has been completed, and the Ulsoor tank supply abandoned.

13. On the water-supply generally of Madras stations, we are glad to learn from the Surgeon-General that constant attention was being devoted to the sources, and that periodical analyses were being made, with this result, that the waters were generally satisfactory as to quality, and he adds that "there can be no doubt that the periodical analyses caused stricter attention to be paid to the sources of supply."

14. *Drainage of stations.*—At Madras stations, as at all others in India, the great predisposing fever cause is the state of the subsoil, and the absence of provisions for freeing it from water immediately the rain begins to fall. In our Suggestions we have laid down the principles to be kept in view in dealing with this most important improvement, both as regards surface and subsoil drainage, and we can only add that the fever admissions in a preceding table foreshadow the fever history of British troops in Madras, and will continue to do so until the subject is taken in hand, and the stations are drained.

15. These are the leading points in the reports under review which appear to call for notice. All of them contain really practical sanitary information, given in a few words, and the general results may be summed up as follows:—

(1.) That the health of European troops in Madras Presidency has undergone considerable improvement, which may be fairly attributed, so far as present facts go, to the sanitary work already accomplished at the stations.

(2.) That this result is sufficient to justify the authorities in pressing forwards the required improvements.

(3.) That certain stations require more active and extensive works than others, and amongst the rest Bangalore, which requires a pure water-supply.

Lastly. That the great desideratum, as shown by the disease and death statistics, is a very efficient surface and subsoil drainage of stations.

1st August 1884.

LIBRARY OF THE BOMBAY BRANCH OF THE ROYAL ASIATIC SOCIETY

No. 16.

Memorandum of the Army Sanitary Commission on the Medical History of the European Troops in the Bombay Command for 1882.

1. There were 10 arrivals of troopships at Bombay during the trooping season 1882-83. The first was on 30th October 1882, and the latest on the 11th April 1883. The following were the numbers disembarked at Bombay:—

Officers	569
Ladies	115
Children	63
Men	2,228
Women	305
Children	459
Female servants	17

The first troopship of the season, the "Euphrates," carried officers and men from Alexandria, and families from Mediterranean stations.

2. During these outward voyages there were 879 admissions and three deaths among the troops. One of the deaths was from pneumonia, one from remittent fever, and one from enteric fever. It ought to be stated that there were 20 admissions for pneumonia, of which 9 took place during the second voyage of the "Euphrates," and these were attributed by the medical officer in charge "to cold and insufficient clothing, some of these men having not even a flannel shirt." These facts and the mischief resulting require no comment.

3. Of the 879 admissions, those from venereal diseases stood as follows:—

Primary syphilis	127
Secondary syphilis	21
Gonorrhœa and its sequelæ	182
Total	330

The ratio from this class of affections was about 37 per 1,000 on the numbers embarked at the outports. But in the table the ratios are calculated on the average strength for a year, which was 754. Consequently the ratios apply not to the real point at issue, namely, the proportion of cases to strength developed during the outward voyages, which was the cause of complaint on the part of the Bombay authorities.

Taken on the annual strength the ratios were of course very much higher, as will be seen from these figures:—

	Ratios per 1,000 per Annum.
Primary syphilis	168·4
Secondary syphilis	27·9
Gonorrhœa	233·4
Gonorrhœa, sequelæa of	8·0
Total	437·7

If the statistical comparison were altogether admissible, the same diseases, which yielded an admission-rate at the Bombay stations of 200·1 per 1,000 per annum, would appear to have yielded a corresponding ratio for the voyages of 437·7 per 1,000. This will be enough to state on the question of ratios, but otherwise the fact is sufficiently startling, that during a month's voyage of 9,228 men, who bore no trace of the disease on embarkation, 330 cases of veneral disease should have become developed.

4. One officer died of intestinal disease, which did not admit of a chance of successful treatment, and one child died from congestion of the brain. The sanitary condition of the troopships is stated to have been good, the accommodation sufficient, and the quality and quantity of the provisions satisfactory.

As regards dates of arrival at Bombay, out of a strength of 9,228 men embarked, 6,651 would have arrived by the end of January, and the remainder between the 7th of March and the 11th April.

5. There were 16 return voyages from Bombay between 31st October 1882 and 1st May 1883, of which 11 were made by the ordinary troopships. They would arrive in England in a little more than a month after the dates of departure from Bombay.

The following numbers made the homeward voyage:—

Officers	417
Ladies	122
Children	198
Men in health	8,957
Women in health	423
Children in health	1,617
Invalids, men	1,852
Invalids, women	155
Invalids, children	353
Insanes	108
Convicts and bad characters	147

The dates of departure show that 1,149 male invalids left Bombay late enough to arrive at home in the warmer part of the spring. But the remainder would all arrive in cold weather.

Army in Bombay.—The average annual strength of troops on service was 10,197. The admissions were 14,338, the deaths 106, of which 14 took place out of hospital. The average number constantly sick was 626·90. These data give the following ratios per 1,000:—

Admissions	1,406·1
Deaths	10·39
Constantly sick	61·48

The invaliding amounted to 35·11 per 1,000 strength. These ratios showed greatly improved health during 1882.

7. The chief admission cause was paroxysmal fever, from which 128 men were constantly in hospital. The admission-rate from this cause was 498·5 per 1,000; but the previous average three years rate was 898 per 1,000, showing a great reduction. There were 812 admissions from continued fevers, 10 admissions from cholera, primary syphilis is credited with 706 admissions, and secondary syphilis with 254. Gonorrhœa and its results gave rise to 1,080 admissions, so that admissions from the venereal group were 2,040. After fevers, venereal admissions were the most numerous, and then followed diseases of the digestive system with 1,863 admissions.

We shall state briefly the facts regarding the chief death causes of the year.

8. *Cholera.*—The entire cholera mortality took place in the last half of the year, and at three stations only. At another station there was two non-fatal cases. The whole are shown in this abstract.

Stations.	Cholera.	
	Cases.	Deaths.
Deolalee	2	—
Nusseerabad	6	5
Neemuch	1	1
Indore	1	1
Total	10	7

9. *Enteric fever.*—Of this fatal disease there were in all 43 cases and 18 deaths, and they took place at the following stations:—

Stations.	Enteric Fever.	
	Cases.	Deaths.
Bombay	9	4
Belgaum	2	2
Aden	1	1
Kurrachee	7	1
Poona	1	—
Ahmednagar	1	—
Mhow	3	1
Nusseerabad	13	8
Indore	1	—
Neemuh	6	1
Total	43	18

When compared with the proportion of deaths to cases, it almost appears as if, at Kurrachee and Neemuch, there had been a number of continued fever cases with enteric complications which it was difficult to distinguish during life from true enteric fever. There were in the whole command 812 continued fever cases, of which 19 proved fatal, and of these, as we have seen, 18 were enteric fever deaths. To paroxysmal fevers were attributed 10 deaths, raising the total fever mortality to 29 deaths, or 27·3 per cent. of the total mortality of the year.

10. Under diseases of the digestive system are ranked dysentery, diarrhœa, and hepatic disease, from which there have been reductions in admissions and deaths in all the circles. The ratios for 1882 were the following:—

Diseases.	Admission per 1,000.	Deaths per 1,000.
Dysentery	12·6	0·20
Diarrhœa	47·0	0·10
Hepatitis and abscess of liver	18·0	0·69
Total	78·0	0·99

There were in all 133 cases and two deaths from dysentery, and 184 cases and seven deaths from hepatitis, &c., which are the more important diseases. We can only hope that the reduction in 1882 represents the spread of temperance and better personal management.

11. The next abstract gives the admission and death-rates, together with the invaliding in the three arms, leaving out the smaller services.

Arms.	Ratios per 1,000.			
	Admissions.	Deaths.	Invalids.	Constantly Sick.
Cavalry	1,094·8	6·16	43·12	59·22
Artillery	1,249·9	10·32	34·01	56·32
Infantry	1,538·1	19·98	36·06	66·17

It will be seen that the infantry yield the largest proportions of all the elements of inefficiency except as regards invaliding.

The fact has been long known, and has been partly ascribed to the less active and more sedentary lives of the infantry, and to intemperate and vicious habits following thereon. It is satisfactory, however, to find that mortality and invaliding showed a marked reduction in all the ranks, except in the case of commissioned officers, who sustained an increase over the previous average mortality of a single death.

12. The facts under this head are shown in the following abstract:—

Ranks.	Ratio per 1,000 Strength.			
	Deaths.		Invalids.	
	10 Years' Average, 1872-81.	1882.	10 Years' Average, 1872-81.	1882.
Officers	13·23	19·61	35·33	39·02
Non-commissioned officers	19·38	14·33	43·71	40·47
Privates	15·10	9·38	48·60	34·40

The lower rates of 1882 do not, however, represent an absolute total gain, because the death-rates vary considerably in individual years and may rise again; all the table shows is, that 1882 had rates much below the average except in deaths of officers, and it is hence hopeful for the future, if sanitary work and improved personal habits among the men are pressed forwards. A little relaxation in effort would soon show itself in the statistics by higher inefficiency rates.

13. Similar statistical data are given for each station, but they can scarcely be used for comparison, as many of the stations are only occupied by a few men. There are certain of them, however, which give evidence of persistent unhealthiness, and hence require notice. Mhow, for example, with 1,350 men, had an admission-rate, in 1882, of 1,573·3 per 1,000, which is very high, but is still nearly 200 per 1,000 under the previous 10 years' average. Neemuch, in the same way, out of a strength of 434, had an admission-rate of 2,912·4 per 1,000, against a previous 10 years' average of 2,130·7 per 1,000, showing an increase in this case of 800 per 1,000. In both of these cases there had been a reduction in death-rates from a 10 years' average of 11·23 per 1,000 to 6·67 per 1,000 in the case of Mhow, and from 26·69 per 1,000 to 16·13 per 1,000 in the case of Neemuch. Nusseerabad shows the most persistent unhealthiness, as is proved by the fact that its 10 years' average admissions were 1,744·3 per 1,000. In 1882 the rate was lower, namely, 1,357·8 per 1,000; but the amount of fatal disease has been much the same, namely, a 10 years' average death-rate of 23·06 per 1,000, represented in 1882 by a ratio of 23·94 per 1,000. The strength at Nusseerabad was 668 men. At Kurrachee, with 798 men, the average admission-rate of 10 years was 1,793·2 per 1,000, which was very high; but in 1882 this rate had risen to 2,492·5 per 1,000, while the 10 years' average death-rate, which was 18·89 per 1,000, had fallen in 1882 to 3·76 per 1,000. At stations with few troops very little difference in the numbers of admissions and deaths either raises or lowers unduly the ratios. But, making allowance for this, the station rates appear to show that good local sanitary work has been done, which has borne fruit, except in cases where there are local malaria causes which have not yet been dealt with. There the admissions are high; and the practical teaching of the present report is that, while there are stations which require special drainage measures, at all the others much good may be done by simple drainage for ridding the subsoil of water. Three stations, Mhow, Neemuch, and Nusseerabad, have been specially examined and reported on by Mr. Hewlett, the Sanitary Commissioner of Bombay, and we have discussed his reports elsewhere. There is some information, however, in regard to Neemuch which may be here quoted, as confirming our previously expressed opinion as to the causes of unhealthiness there. The medical officer in charge says, "The "remarks I have made on the physical geography of this station and its vicinity will, I think, suffice "to show that the site of the barracks occupied by the European troops is an eminently malarious "one. To the west is the Leora tank, from which the wind frequently blows directly on to the "barracks, and which during and after the monsoon is situated in a swamp. . . . . Again, to "the north of the barracks is a large tract of land which is always, undoubtedly, a source of malaria. "The broken ground in the vicinity of the principal nullahs must also, after an unusually heavy "rainfall, exhale malaria in the superficial drains which permeate the barracks in every direction. "The water is quite close to the surface during and immediately after the monsoon."

The remarkable fact about Neemuch is that in former times it was reputed healthy, while last year 434 men yielded 1,264 admissions to hospital and seven deaths, or 16·3 per 1,000, its 10 years' rate having reached 26·96 per 1,000. We have elsewhere suggested that the facts as a whole appear to show the necessity of spending large sums of money on drainage works, or, failing this, of abandoning the station as one for European troops.

14. There is one station, Belgaum, to which we have called attention in former years on account of what may be called its persistent healthiness, and it might repay the trouble to examine into the causes of this peculiarity, and compare the facts with those regarding the more unhealthy stations. This station had an average strength of troops in 1882 of 812, which sent 824 admissions to hospital, or 848·7 per 1,000. There were seven deaths in the course of the year, or in the ratio of 8·62 per 1,000, which, nevertheless, exceeded the previous 10 years' average, which was 7·24 per 1,000. Among troops of the same nationality, occupying Nusseerabad and Neemuch on the one hand and

Belgaum on the other, there is strong *primâ facie* evidence of presence of local causes in the first two stations not present at Belgaum.

15 Appended to the report under review is a long correspondence on the subject of Mr. Hewlett's reports on Neemuch, Nusseerabad, and Mhow already referred to, further extended in documents sent to this Commission by the India Office, on which a few words may be said.

There appears to be no indisposition on the part of the authorities to do what they can for the improvement of the stations. In this aspect of the case the main difficulty is the expense; but we have always contended that the continued saving of efficiency by the reduction of the various elements of inefficiency, involves a far larger economy to the State than would be effected by withholding the capital outlay required for the improvements. But at this point we are met by another difficulty, for Mr. Hewlett's thoroughly skilled opinions and advice on purely sanitary subjects are apparently called in question by authorities who, in the very nature of the case, have not the same means of estimating the facts as their Sanitary Commissioner has had. The man most calculated to advance the State interests in these matters is not the man to smooth over disagreeable facts and mistakes such as those at Neemuch and Nusseerabad. We cannot enter further on the discussion of these differences of view, and we have alluded to them solely for the purpose of setting prominently forwards the obvious principle in sanitary administration, as in all other State departments, that the opinion of the skilled officer is the one to be adopted and acted on if possible, and that any cause for not adopting the advice tendered should not rest on a difference of view between the unskilled and the skilled official, but on the impracticibility or only partial practibility of giving effect to the skilled advice, which is always a matter admitting of free discussion.

16. Under the head of "General Remarks" there are some practical points referred to by the Surgeon-General which appear to be worthy of note. A few years ago some exception was taken to the ventilation of certain barracks at Bombay stations on account of blasts of cold air falling on the men at night. This, however, appears to be not a common occurrence, for the Surgeon-General says that, "From 6 o'clock in the evening till late in the following day there is an absence of all movement "of air. The smallest leaf on the tree is scarcely stirred. An atmosphere like peasoup, composed of "smoke from the bazaar and particles of heated dust or sand, rests like a pall upon everything. At "such times people feel as if they could hardly breathe, and it is then that heat apoplexy occurs. "Sleep at night is often unobtainable, even under a punkah with a fringe that all but touches the "face. At such times as these barrack-rooms can hardly be too lofty, too much ventilated, or have "too many openings to the air."

The probability is, however, that these principles, though admissible at many stations, do not cover the whole ground, for there is as distinct evidence that if movement of the air is set up outside it passes over the men in bed, chills them, and induces hepatic affections and fever attacks at some stations. The practical point to be kept in view is, that wherever cold currents of night air are allowed to fall on men while in bed there is more or less danger of chills, and hence the necessity of proper ventilating arrangements in all such cases. The objection lies not against ventilation, however abundant, but against cold-air currents, which can always be prevented while the ventilation itself is not interfered with.

17. The Surgeon-General is, however, quite right in holding that, whatever may be the effect of a chill in setting up a fever paroxysm, the underlying cause which must be dealt with is malaria, which has its source "in swampy ground, or ground that has long been covered by water during the rainy season."

He further points out that it is not sufficient, while selecting a site for barracks, to look merely at the immediate surroundings, and that it is necessary to examine the country for a distance with special reference not only to its condition but to the direction of prevailing winds.

But where barracks have been built on a badly-selected site, then the bad spots should be drained; but if this cannot be done, "the only remedy left to us is to surround the dangerous locality with "belts of trees, and, if it can be done, to plant trees on the ground itself. Complete cultivation of "the ground, and exhausting the malaria from the soil, would, of course, be the most radical cure we "could adopt, as it is certain that malaria disappears before cultivation."

He further cites the experience obtained by planting eucalyptus in Italy, by which the subsoil water level had been lowered from 12 centimetres to 1·95 metres below the surface.

The question he raises about the difficulties of subsoil drainage with rocky soils is one of ordinary sanitary work. Wherever in a tropical country there is a subsoil of sufficient depth to retain water, and if there be a drainage outlet, it should be drained. Wherever there is an underlying irregular rocky subsoil with hollows retaining water, the hollows, if possible, should be drained, but situations of this kind should be avoided. Again, where the actual subsoil, although retaining water after rain, is too shallow to be drained, the best remedy is grass or some low-growing vegetation. Bare surfaces in such positions are not safe. Tree planting, as long since practised in Algeria, particularly of the eucalyptus, for the purpose of sanitation of local malaria-producing ground can be tried especially with the eucalyptus, if it will grow. Of course, the dangerous influence of newly-turned up ground for buildings, roads, clearings, &c. has been long known in warm climates, but this can be provided against by known remedies which we have often pointed out. It is not without interest to remark, that the Surgeon-General, in discussing the sanitary history of the year, has been apparently unconsciously led to lay great stress on the local malaria question, which lies at the root of unhealthiness at most Indian stations, but unhappily, although its paramount importance has been long known and insisted on year after year by ourselves, it has as yet occupied little practical attention in India.

Lastly. These are the main practical points requiring notice in the present year's Report. The statistics show that the current sanitary work of past years has improved the general health of the Bombay European army. But the malaria-generating condition of the subsoil at many stations remains the same. Some stations, as is shown by the statistics, are worse in this respect than others, and in three of these the skilled inquiries carried out by the Sanitary Commissioner have led us directly to the causes.

The only question that now arises is whether, at any reasonable outlay, these causes can be wholly or partially removed by such an outlay as the State would be justified in incurring, or whether benefit might not be obtained by removing the troops during the unhealthy season. The question is a financial and engineering one, for its sanitary relations may now be considered as settled. As the stations differ in their sanitary condition, we would, in conclusion, suggest that most benefit to the general health of the Bombay army would be obtained by spending efforts on improving those which statistics have hitherto shown to stand most in need of improvement.

12th August 1884.

No. 17.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT on ENTERIC FEVER by Deputy Surgeon-General J. W. HEWLETT, SANITARY COMMISSIONER with the GOVERNMENT of BOMBAY, with accompanying correspondence, 1884.

1. This Report is the result of a long and laborious investigation by a skilled sanitary officer into the conditions attending the occurrence of enteric fever cases among European troops at stations in the Bombay Presidency, and its object is to make such proposals of a purely practical nature founded on the observed facts as may lead to a diminution of attacks from this formidable disease among the troops. We are desirous that the object of this inquiry should be clearly kept in view, for although Mr. Hewlett has given very full extracts from authorities on the nature, pathology, and theoretic causes of the disease, this is done simply that the officers to whom belongs the improvement of health of troops may be put in possession of the various opinions which have been held on these subjects.

2. All sanitary work involves outlay of somebody else's money, and the final object of both work and expenditure is improvement of health, and while fully admitting the interest and value of every contribution which has been made to the history of enteric fever, the results can only be, of course, made use of in so far as they are practical, and have been sustained more or less by previous or by analogous experience. For example, it may be true that enteric fevers and other fevers may be conveyed by disease particles so minute or so transparent as not to be recognisable with the highest powers of the microscope, which means that their existence is matter of inference and nothing more, but it is quite evident that a pathology such as this does not admit of being translated into sanitary action, nor would it justify either the expenditure of other people's money or the infringement of personal liberty or convenience. But the case is far otherwise when there is skilled testimony to the fact that enteric fever is so closely related to marsh fevers arising from every-day observable marsh conditions as apparently to justify the opinion held by some authorities that a change of name of the fever to "typho-malarial fever" should be made.

3. Again, it has been held by competent Indian pathologists, while admitting the special pathology of enteric fever, that in a certain proportion of such cases the disease known by the specific name only makes its presence manifest after a previous disease history not belonging to enteric fever, but to intermittent or remittent fevers, and in certain cases it has been held that *post mortem* enteric fever complications were in reality a result of Indian fevers, and hence the specific character of enteric fever has been sometimes denied.

4. In sanitary work the pathology of "invisible" disease particles admits of no application; but if enteric fever is an observed concomitant of marsh fevers or of ordinary Indian fevers, the removable causes of which are more or less known, or of sending immature soldiers to India, or of observed defects in subsoils, water-supply, barrack construction, and the like, we have at once a foundation on which to rest our work. We have called attention to these points in order that the contents of Mr. Hewlett's opening chapter may not be misunderstood by executive officers who might find it somewhat difficult to make their way through the tangle of disease speculations which he has extracted from current literature, and we shall next proceed to give some account of the work itself. But in doing this it is necessary to put forward some excuse for discussing matters connected with this fever which we have time after time made the subject of Memoranda, and our excuse must be the great importance of the subject, and the necessity for restating the whole case as it has been presented anew in the present Report.

5. The course usually adopted with so important a disease as enteric fever is to deal with the disease as such, and to attempt to discover local, personal, and climatic conditions sufficient to

account for its presence specially. This course is attended by the disadvantage that it tends to limit unduly the history both pathological and etiological of the fever, and, by doing so, to shut out facts which otherwise might render us important assistance in understanding the disease and its causes.

We are glad to see that Mr. Hewlett has followed a different course in the present Report, so that, as the Surgeon-General states, "it seems to be more than a report on enteric fever only. It may, "perhaps, be more correctly regarded as an inquiry into the hygienic and sanitary conditions of "military stations in this Presidency, and into all circumstances that can affect the health of the "British soldier in India, the object being to discover, if possible, whether there is anything in his "daily life, the environments by which he is surrounded, the food and drink he partakes of, the "duties he is called on to perform, &c., which can predispose him to attacks of this fever when "exposed to any agency which can originate it."

6. Mr. Hewlett commences his inquiry with the subject, the soldier, and he shows anew how large an amount of the enteric fever which infests European troops falls on young ages in Bombay, as it does in other regions of India. By adopting a 10 years' period, he gives the aggregate strength of European troops at assigned ages in Bombay as follows:—

Ages.	Aggregate Strength, 1872–81.
Under 20	4,129
20 to 24	36,645
25 to 29	32,158
30 to 34	16,264
35 to 39	10,443
40 and upwards	2,299
Total aggregate	101,938

This abstract shows that 40 per cent. of the European Army in India during these 10 years was under 25 years of age.

7. These facts regarding the constitution of the Army prepare the way for discussing the question of ages in relation to liability to enteric fever, and as this relation was established by the late Dr. Murchison for cases admitted to the London Fever Hospital, we shall extract from the Report under review his tabular statement, which establishes his position that "persons under 30 are more than four times as liable to enteric fever as persons over 30."

The table is founded on 5,911 admissions, and may safely be accepted as showing the normal relation of enteric fever to age in London at least.

Ages.	Per-centage of Attacks.	Ages.	Per-centage of Attacks.
Under 5 years	0·98	45 to 49	1·08
5 to 9	9·44	50 to 54	·60
10 to 14	18·16	55 to 59	·33
15 to 19	26·86	60 to 64	·33
20 to 24	19·69	65 to 69	·08
25 to 29	10·15	70 to 74	·00
30 to 34	5·36	75 to 79	·03
35 to 39	3·40	Ages not specified	1·30
40 to 44	2·09		

Soldiers' ages in India which have been practically under discussion in relation to liability to enteric fever are those under 25; and, assuming that all such are included between the ages 15 to 25 in this table, we find that, according to London experience, no less than 46·55 per cent. of all enteric fever admissions fall on the same ages as suffer most in India. The importance of this fact is that it shows that liability to enteric fever attacks at the soldiers' ages is a home liability, and it is this home liability which is transported to Indian climates and to Indian conditions of life and service, there to become rapidly developed and intensified.

8. The following abstract shows the liability to enteric fever of troops at different ages in India after their arrival there, but in this table not the cases but the deaths are classified according to age.

Ages.	Per-centages of Enteric Fever Deaths.
Under 20	26·11
20 to 24	43·58
25 to 29	23·19
30 and upwards	7·12
Total deaths	100·00

In London, 46·55 per cent. of admissions become at the same ages in India replaced by 69·69 per cent. of the deaths. In order to show what this rate really means, it may be further stated that, out of 246 enteric fever deaths, 138 took place at ages under 25, and that, out of 509 deaths from all causes at the same ages, 138 were from enteric fever. Another element in the case is the influence of length of service, which falls most heavily on the younger ages. Thus, out of 105 enteric fever deaths among soldiers having one year of service or under, no fewer than 84 took place in men under 25, while among men of the same ages and with two years' service and under, out of 147 enteric fever deaths 112 were under 25 years of age.

This subject is fully discussed by Mr. Hewlett; we have often insisted on its importance to the efficiency of the Indian European Army, and we shall merely sum up the evidence with the statement, that before young soldiers leave England for India they have already a definite tendency to enteric fever upon them due to their ages, that they carry this tendency with them after a rapid voyage to Indian climates, where the great death-cause everywhere is fever, that this fever tendency is immediately developed when they arrive, and large numbers of men under 25, who might have been useful soldiers, are swept away within the first two years of residence.

9. As already stated, the first influence to which troops on arriving in India are exposed is rise of temperature, and perhaps the simplest way of showing what this amounts to will be to place side the monthly temperature means for three home stations, and similar data for three enteric fever stations in Bombay. These data are contained in the following abstract, and are sufficient for our object:—

Months.	Mean Monthly Temperature.						Enteric Fever, 10 Years, at Bombay Stations.	
	Aldershot.	Edinburgh.	Curragh Camp.	Neemuch.	Nusseerabad.	Kurrachee.	Admissions.	Deaths.
January	32·9	33·6	35·6	61·3	58·2	63·1	22	12
February	42·5	40·7	44·6	68·3	70·0	66·5	21	13
March	46·0	43·2	45·7	75·5	79·1	78·5	16	3
April	49·8	42·5	49·4	84·6	85·3	79·3	34	17
May	53·3	51·5	53·8	88·7	93·8	82·5	34	21
June	56·8	53·8	59·3	84·9	91·7	85·5	15	12
July	62·7	59·1	59·1	78·5	85·4	84·2	14	11
August	65·6	60·4	61·4	77·2	83·8	80·9	42	19
September	58·0	52·8	53·2	77·9	83·8	80·6	70	49
October	50·5	47·5	48·5	77·1	80·8	75·0	56	28
November	38·3	38·7	42·1	71·7	76·3	71·3	47	28
December	37·9	38·0	39·0	65·3	65·4	65·8	30	19
Annual mean temperature	49·5	46·8	49·2	75·9	78·7	75·8	401	232

This table shows clearly how vast is the difference between the home climates which the soldier leaves when he goes on Indian service and the climates he has to contend against when he arrives there. The physiological problem which he has constitutionally to encounter amounts to the addition of 58 per cent. to the temperature he was born and reared in, within a year of his arrival in India. His constitution must either adapt itself to the change or suffer. It will be seen that this is a matter quite apart from local disease causes, and, in fact, refers solely to the subject, the soldier, or to the civilian entering on Indian service, and in both the organism is handicapped before the real struggle with Indian climatic or local causes begins.

10. An important element in the question of temperature is daily variation, the amount of which points to another call which is made on the constitution of young men going to India. Daily temperature variation is of course much greater than average ranges for months or years, but it is usual to give the differences by months. At Aldershot the lowest monthly range is 8·6° in January, the highest 24·8° in August. These are the average daily ranges for the month. At Edinburgh the average daily ranges lie between 8·5° in February and 17·5° in May. In the same way the ranges are between 13·5° in December and 23·4° in May at the Curragh. The daily differences between maxima and minima which these averages represent indicate the amount of compensation which the organism must make for the home climates. But if we take the Indian daily ranges the case is very different. At Kurrachee, for example, we find the monthly ranges vary between 15° and 47°. If we assume the Ajmere data as representing the climates of Nusseerabad and Neemuch, we shall have monthly variations to account with of nearly 50°. Of course, as already stated, these figures are only a kind of index to the daily variations, which are very much greater.

11. These are no more than the elements of temperature with which young men have to contend on first entering the country, and it may be worth while to inquire whether the statistics of enteric fever show any relation to these elements, apart from other elements of climate. For this purpose we must refer back to the preceding table, and we shall take the admissions as affording more reliable means of comparison than the deaths, which necessarily include cases admitted in the previous months. It will be seen from these data that the months of highest enteric fever admission-rates are not necessarily the hottest months. The admissions increase with rising temperature until the maximum of temperature is reached. During this period a sudden check is put on the disease, and then the admissions rise with falling temperature after July, and it is at this period that another very important element enters to modify the fever history, not only of these Bombay stations, but of the whole of India, and this is the rainfall.

12. Up to this point we have traced the young soldier from his home station, and its temperatures and ranges, to the far higher temperatures and ranges of Indian climates, and we shall next see that rainfall, with development of what, for want of a scientific knowledge we call "malaria," exerts a direct and powerful influence on the amount of fever among troops, and then we shall have to trace the relation of these fevers to the present subject of inquiry, enteric fever. The simplest way to show the relation of climate to the prevalence of fever will be to place side by side the average monthly fever admissions among European troops in Bombay Presidency during the 10 years' period 1870–79, in Dr. Stephens' tables, with the monthly estimate of climate given by Mr. Lumsdaine in his annual sanitary reports.

Months.	Admission Rates per 1,000 Strength from Fever.			Empirical Seasons.
	Enteric Fever.	Intermittent.	Remittent Continued.	
January	·2	30·6	4·1	Cold.
February	·2	21·7	4·6	"
March	·2	23·2	8·4	"
April	·3	25·3	11·0	Hot and dry.
May	·2	36·7	12·0	" "
June	·1	35·7	13·3	Rainy.
July	·1	45·3	12·0	"
August	·3	52·3	13·3	"
September	·6	68·9	15·2	"
October	·4	32·0	16·7	Hot and damp.
November	·2	65·5	12·0	" "
December	·2	46·8	8·3	Cold.
Total	3·1	528·5	131·4	

Soon after the setting in of rains the fever admissions begin to increase, but it is in the drying up months that they attain their maximum degree of prevalence until they are checked by cold. Enteric fever increases at the same time as the other fevers, but their relative mortality is a different matter. The average annual death-rate from enteric fever during the same 10 years was 1·75 per 1,000 out of its annual admission-rate of 3·1 per 1,000, while the death-rate from all other fevers was 1·14 per 1,000 strength out of their aggregate admission-rate of 659·9 per 1,000. Rainfall differs greatly in amount in different parts of Bombay Presidency. The lowest annual fall is 7·38 inches at Kurrachee, where the average admissions from enteric fever have been 6 per 1,000, and the deaths 3·63 per 1,000 strength. It is important to remark that at this station the admissions from intermittent fever have averaged 166·7 per 1,000, and from remittent and continued fevers 184·4 per 1,000. These facts prove the existence of local causes of malaria apart from rainfall, but in this instance again we have a large part of the admissions taking place in the monsoon months, June to September, when the rainfall is 5·35 inches.

Nasirabad has a 10 years' average admission-rate from enteric fever of 6·3 per 1,000, and a corresponding death-rate of 4·24 per 1,000. Its admission-rate from intermittent fever was no less than 745·9 per 1,000, and for remittent and continued fevers 81·4 per 1000, and yet its rainfall is only 21·04 inches, all of which, except a fraction, falls between June and September, which months also yield the greater proportion of fever admissions.

At Neemuch the admissions from enteric fever show a 10 years' average of 5·4 per 1,000, and from all fevers, chiefly intermittent, a rate of no less than 1,305·7, and a death-rate of 2·11 per 1,000. The rainfall at Neemuch is 31·97 inches, of which 30·25 inches fall in four months, June to September. At this station, out of 5,562 admissions from paroxysmal and continued fevers, all, except 665, took place between June and the end of the year. August and September are the chief enteric fever months.

13. In this analysis there are facts which do not admit of being disputed: (1), it is proved that men of the ages which yield the highest fever proclivities in India already present the same proclivity at home; (2), that, besides the struggle which has everywhere to be carried on during the growing periods of life, young men sent to India have to contend against the influence of unaccustomed excesses of temperature and temperature ranges, which do most injury on the first introduction to Indian service of unformed constitutions; (3) that, as proved by the disease statistics, there is a large prevalence of those fevers to which the term "malarial" is applied at all the stations of the Bombay Army, as well as of continued and enteric fevers, and that young newly arrived soldiers are most liable to suffer from fevers, especially from enteric fever, at these stations; (4) that the period of the rains and drying up of the rains, is the fever period, but enteric fever is not so much affected by rain as are paroxysmal fevers. Moreover, the amount of fever is not in proportion to the amount of rain, and must be connected with local malarial causes which may be intensified, but not originated by the seasonal rains. In other words, these malarial causes must be sought in the station subsoil or in its vicinity.

14. At first sight these facts would be apparently be sufficient to account for the entire losses from fever, but as part of the question, having a direct bearing on measures of prevention, it is necessary to discuss with the facts in Mr. Hewlett's Report before us, and as far as we have the means of doing so, the relation which enteric fever bears to the other fevers in India. Is it a specific communicable fever, like small-pox for instance, or is it the fatal stage of ordinary Indian fevers, especially of those

of remittent and continued type? This subject has often been discussed, and what we have to do at present is to take the facts adduced by Mr. Hewlett simply as evidence in the case, without necessarily accepting them as finally settling the points at issue.

The first paragraph of Chapter V. in the Report stands as follows:—

"From an examination of the cases which have been forwarded to me by medical officers, it appears "that it is quite the exception for the disease on the patient's first admission into hospital to be "diagnosed as enteric fever, as in a large majority it is ascribed to either intermittent, remittent, or "continued fever, and only when enteric complications arise is the disease changed."

"I also notice that the temperature charts in a large number of cases do not present the same "fluctuations as are met with in England, or as depicted by Wunderlich and other authors as "diagnostic of enteric fever. The absence of the characteristic eruption is also very frequently "observed, and sometimes there appear to be no abdominal symptoms so marked as to attract "attention until a *post mortem* examination reveals the presence of ulceration in the solitary or "agminated glands of the lower part of the ileum."

And even as regards the ulceration itself, Mr. Hewlett states that "it is not an easy matter to make a distinction between it and other ulcers." He adduces the opinion of Dr. Morehead that "disease of Peyer's glands, either in a state of turgescence or ulceration, is not a morbid state "peculiar to typhoid fever. It occurs in cholera, in protracted diarrhœa, in acute muco-enterites, "as an occasional complication in remittent fever, and a frequent one in phthisis pulmonalis."

This part of the question is illustrated by filled-up case sheets and by temperature charts. But it is not denied that cases of true enteric fever have been traced from beginning to end in India. The facts as a whole are adduced to show that, admitting this much, in the majority of cases, the earlier history is not that of enteric fever, but of ordinary intermittents, remittents, and continued fevers, in the course of which enteric fever develops itself or shows that it has been the fatal fever by its *post mortem* appearances. And as regards the origin and spread of enteric itself, Mr. Hewlett says that, from the evidence he has been able to gather, "there seems to be no ground for believing that "enteric fever, which annually attacks and destroys so many young soldiers shortly after their "arrival in India, is in all or even in the great majority of cases due to a specific poison derived "from the intestines of a previously affected person."

15. These statements appear to include the leading practical facts on the whole subject, apart from attempts to account for them by calling in the aid of particulate disease elements. If such were proved to exist they would, of course, enter into the question of prevention. But at present we have to consider how to diminish the amount and fatality of fevers which are apparently related not only to young ages suddenly introduced to Indian climates, with their high and variable temperatures and monsoon rains, but which are, many of them, malarial in character, and, as such, are related to general and local malarial causes, including under this term not only marshy conditions, but all general or local conditions such as are known as predisposing causes of fever.

16. This part of the inquiry is one for which Mr. Hewlett's skilled assistance was utilized by the Government of Bombay, and it includes the local insanitary influences of bazaars and native towns in the vicinity of stations, the condition and influence of local position of individual barrack blocks, the condition of drainage of subsoils, of ground near stations, of conservancy, water-supply and other local causes.

The first step in such an investigation is, of course, to deduce the fever history of the stations, and this is given for 10 years ending 31st December 1881, as follows:—

Stations.	Fever Admissions per 1,000 excluding Enteric Fever.	Total Deaths in 10 Years.				Death-rate per 1,000 Strength.			
		Enteric.	Intermittent.	Remittent.	Continued.	Enteric.	Intermittent.	Remittent.	Continued.
Kurrachee and Ghizree	944·5	47	—	6	3	5·8	—	0·7	0·4
Hyderabad	858·3	7	—	2	—	1·9	—	0·5	—
Bombay	1,001·9	3	3	5	1	0·6	0·6	0·9	0·2
Colaba Depôt	388·3	—	—	2	1	—	—	5·6	2·8
Baroda, 1876-81	1,576·4	3	—	1	—	2·5	—	0·8	—
Ahmedabad and Baroda to 1875	905·4	9	—	3	2	3·5	—	1·2	0·8
Deesa	595·6	11	2	5	1	1·8	0·3	0·8	0·2
Mount Abu	1,160·3	—	—	—	—	—	—	—	—
Taragarh	842·3	4	—	—	—	11·9	—	—	—
Nusseerabad	704·8	30	—	10	—	4·8	—	1·6	—
Neemuch	1,344·4	11	1	6	—	2·6	0·2	1·4	—
Indore	732·7	1	—	3	—	1·1	—	3·3	—
Mhow	757·5	37	3	6	1	2·8	0·2	0·5	0·1
Asirgarh	910·8	1	—	2	—	1·3	—	2·3	—

Poona and Kirkee	675·6	36	3	7	—	1·6	0·1	0·3	—
Purhandar	691·2	2	—	1	—	2·2	—	1·1	—
Khandala Depôt	746·2	—	—	1	—	—	—	3·1	—
Satara	473·2	2	1	—	—	1·2	0·6	—	—
Belgaum	338·0	2	—	4	—	1·0	—	0·4	—
Aden	334·6	4	—	1	2	0·5	—	0·1	0·3
South Afghanistan, 1880	987·7	10	—	10	—	23·6	—	23·6	—
Troops Marching	341·0	1	—	4	—	0·4	—	1·6	—
Total	—	232	15	85	11	2·3	0·1	0·8	0·1

This table gives the fever history of every station in Bombay Presidency for an annual average of 10 years, as well as the total fever deaths and their annual rates per 1,000 strength of troops for the same 10 years' period. The deaths from all types of fever and their relative amounts were as follow:—

Fevers.	Deaths.	
	Total Deaths.	Per-centage of Total.
Enteric - - -	232	67·64
Intermittent - - -	15	4·37
Remittent - - -	85	24·78
Continued - - - -	11	3·21
All fevers - -	343	100·00

These figures speak for themselves, and it is quite evident that, out of 343 fatal cases of fever, all of which were submitted to *post mortem* inquiry, and even if no questions be raised as to the diagnosis during life, there were 232 autopsies in which the lesions of enteric fever were found, or in 67·64 per cent. of all the fatal cases. It appears to follow that the real difficulty in estimating the relative frequency of enteric fever lies in the diagnosis, which in India is complicated by the very general prevalence at all the stations of fever of paroxysmal types, as is shown in the preceding table. The fever which, after enteric fever, yields the largest number of deaths, is "remittent," and in the sheets given by Mr. Hewlett this fever type is the one from which transfers to "enteric" fever appear to be most common.

17. Now let us suppose that the disease known in England as "enteric fever" had not been introduced into Indian nomenclature, it is clear that medical officers would have been justified in classing the whole 232 fatal cases entered under the enteric fever head as fatal cases of climatic Indian fevers, and hence the question returns in another form. What characters during life ought to be assumed as proving that a given case of fever is enteric fever? The reply to this question has a special bearing on the treatment, which, of course, lies beyond our sphere of work, but for practical sanitary purposes it is quite obvious that we must group all the fatal fever types under one head and deal with them all on the same principles. And if this course be adopted, the first result that will follow is that the actual per-centage of admissions from all fevers is not a measure of the death-rates of individual stations, for, as is shown in the table, the stations which yield the highest ratios from fatal fever types are not necessarily the stations at which the fever admission-rates are highest, and this brings us to the question really at issue, which is as follows.

18. Given a group of stations with very various per-centages of fever admissions among troops, and at which the ratio of fever deaths is not related to the amount of fever, but to the severity of the cases, by what practical steps can the proportion of the fatal cases be diminished? After many years of discussion and local inquiry it cannot be said that fatal fevers can be traced to any one cause. Were this possible, all fevers, nay all diseases, would be of specific nature rather than the results more or less slow of pathological change. At all events, we have as yet no proof of the supposed fact, and in the present Report Mr. Hewlett has done good service by attacking the problem from the outside, and by raising the question whether the stations as a whole, and in the totality of their sanitary aspects as visible to a skilled and experienced observation, present conditions under which fatal fevers may be expected to occur among their permanent residents. The condition of the stations is discussed in detail, and especially with reference to their drainage, water-supply, conservancy arrangements, barrack construction, bazaars, and neighbourhood. We have noticed on other papers three of the most important of these station reports on Nusseerabad, Neemuch, and Mhow, and we have frequently discussed the condition of other stations where enteric fever cases take place. We shall only add a few illustrative facts.

19. In the preceding station table it is shown that, although the fever admissions among troops exceeded 1,160 per 1,000 at Mount Abu, there had been only two enteric cases, but no fatal fever cases in 10 years. In 1882 this immunity ceased so far as concerned the civil population, and five cases of enteric fever took place, due apparently to emanations from filthy latrines. Mr. Hewlett's judgment on this case is as follows: "Especial care should be taken not to allow latrines for natives "to be placed in such deadly situations as ravines, . . . , and much greater attention should "be paid to the sanitary condition of houses and their surroundings, especially regarding the "servants' houses and privies, &c., as well as with reference to the disposal of wastage water, &c. "This course is imperatively demanded, or else it is easy to foresee that some day an epidemic will "occur which will sweep off those predisposed to it by youth and recent arrival." Here we have a purely local outbreak of enteric fever at a hill station traced to very common insanitary conditions, which may exist at any Indian station.

20. At Taragarh, another hill station, there were four deaths from enteric fever in 10 years, out of a strength of 336 men. The water for convalescents is brought from a well at Ajmere, and contains 72·1 grains of solids per gallon, including no less than 17·15 grains of chlorine, with a high proportion of ammoniacal compounds. The question may be very properly asked, who was responsible for selecting a hill station with such water?

21. Indore has not a very high fever admission-rate, but of the admissions 3·2 per 1,000 were due to enteric fever and 9·6 to cholera, and the remittent fever death-rate had averaged 3·3 per 1,000. The medical officer, in 1878, reported that "the bad state of health of the men in August was "doubtless caused by the nature of the soil around the barrack, hospital, and patcherries. This "year many defects have been apparent which in dryer years were not noticeable,—want of deep "drainage, stinking condition of parts of the soil in barrack floor." We have here causes enough for any amount of fever and bowel complaints.

22. The enteric fever at Ghorpuri barracks, Poona, is described by the medical officer as malarial fever, in course of which "enteric symptoms only developed themselves after prolonged illness," which he ascribes to "the general malarious influence prevalent throughout the lines," and this Mr. Hewlett ascribes to bad selection of site.

23. Belgaum affords experience of an opposite kind. It has one of the lowest fever admission-rates (383 per 1,000), and yet in 10 years it lost 13 men from enteric and remittent fevers, the causes of which must be looked for elsewhere than in malarious position. A neighbouring foul tank and bazaar, a large native town, and imperfect disposal of night-soil appear to have been exciting causes.

24. Baroda and Ahmedabad had 12 enteric fever deaths, besides four from remittent and two from continued fevers. Of the former Mr. Hewlett states that the ill-health of British troops "is *very largely* to be ascribed to the infraction of well established and well recognized sanitary laws." There are political considerations about this station which should be overruled in providing for the health of the occupying troops. Ahmedabad simply exhibits the consequences of a badly selected site. At Ahmednagar there was an outbreak of enteric fever, due apparently to the accidental pollution of the water-supply.

25. Kurrachee, which is a well-known fever station, is described by Mr. Hewlett as follows: "The site of the camp was originally selected without due appreciation of its sanitary defects, as "I suppose no one would now say that it is desirable to have a mangrove swamp four square miles in area to windward at a distance of about a mile and three-quarters from barracks." This evil has been increased by closure of the sea inlet by a railway embankment. But besides these fundamental defects, the whole place requires the work of an experienced sanitary engineer to improve it. We formerly suggested that probably the least expensive remedy would be to remove the station to Ghizree.

26. This brief sketch will be sufficient to show the general character of fever causes at stations, but there are other causes which prevail almost universally, and which are connected with the sanitary condition of bazaars and towns to which soldiers resort,—water supply, habits of the men, &c. In regard to bazaars, &c., Mr. Hewlett says that "almost without exception, they are in an unsatisfactory state from a sanitary point of view." In these bazaars the soldier resorts to the very worst localities, amongst the lowest caste people, where he is surrounded by filth and nuisance, and is exposed to other diseases besides venereal affections. The cantonment magistrate has only limited means of dealing with disease causes such as these places present, but it is quite evident that, in any general measures to be adopted for the prevention of enteric fever, the bazaars must be improved to a much greater extent than has been hitherto done. A similar remark applies to native towns near stations. The Report contains much interesting information on the question of water-supply, provided by the Government analyst. The waters differ very much in purity and impurity at different stations, and even within the same cantonment limits, and the evidence yielded by the analysis shows that, in any scheme for the improvement of a station, the water-supply must be accounted with. Bad wells must be improved or discontinued, and better sources of supply provided, and improved means of distribution must be adopted. The mussack is quite out of date.

27. *Barracks.*—Mr. Hewlett makes some remarks on barracks, which require notice. He says they are generally very fine buildings, but that it was a mistake, in his opinion, to issue standard plans applicable to the whole of India, from Cape Comorin to Peshawar. There can be no doubt of this position, nor of the view that it would be better in the present sanitary condition of sites to have constructed buildings of less expensive character, and which could have been replaced in 20 or 30 years. We have discussed this question in our "Suggestions," and we shall merely repeat that permanent costly buildings should only be erected on carefully prepared and drained sites, because an undrained site is a camp site and nothing more, whatever may be the cost of the buildings, and, like any other camp site, it becomes sodden and unwholesome after a time. When this takes place with a camp it is shifted, as a matter of course, but a costly barrack cannot be so dealt with, and fever among the troops is the result.

28. There are many details in the every-day sanitary administration of stations, which Mr. Hewlett shows could be improved with advantage, but so long as stations are without house and subsoil drainage, no completely efficient sanitary system can be carried out. All that can be done is to aim at the best possible result, with defective means and methods.

29. In dealing with the fever question as a whole, and in its sanitary aspects, it appears to us to be impossible to separate between the fever types. There is no proof of the specific character of Indian enteric fever, or its connection with any specific cause, such as would enable practical measures to be taken against it. This position does not interfere with any opinions formed by medical officers at the bedside, or with any measures founded on them which they may think it desirable to pursue in particular cases. But it amounts to a distinct statement, founded on evidence,

that the doctrine of specific causes does not admit of being practically applied in our endeavours to diminish the prevalence of enteric fever at Indian stations.

30. The first and most important step in this direction is to raise the age at which soldiers are sent on Indian service, and to complete their drill before going out. Second in importance must be considered their location at hill stations, provided these are kept in a healthy condition, which is far from being the case with many of them at present. Then, as regards the stations, Mr. Hewlett's inquiry has shown that, in the present condition of stations, no other remedies are required or indeed are applicable than remedies needed against the whole tribe of fevers. The liability to fevers of every station in Bombay is now well known, and the remedies have been long pointed out. Certain stations scarcely admit of the required improvements except at such a cost as to raise the question of removal of the troops or of the cantonment to a healthy locality. Taking the stations as a whole, if the question were put whether they do or do not present fever characteristics, it would be difficult to say whether in any case a negative reply could be given. They appear all to want drainage of some kind, partial or total, and in the best practicable manner, to drain underground water-holes or to free the whole subsoil as rapidly as possible of water after rain, and so to cleanse it and keep it clean. The intermingling of fever types and the apparent passing of a less dangerous into a fatal type of fever at most of the stations, the universal prevalence of malarial fever together with or passing into fever types known by other experience to be due to filth causes, all point to foul undrained malarial subsoils as causes to be at once dealt with.

31. Again, the sanitary problem presented by any particular station involves the condition of bazaars and native towns or villages frequented by troops. It is known, in regard to cholera, that it first appears among natives before it extends to troops, and a common practice has been to keep troops from going into places where cholera prevails. Precisely the same precaution is required in regard to fevers, which Mr. Hewlett tells us prevail extensively among native population groups, including enteric fever among others. All facts and arguments point in the same direction, namely, that the only way to reduced fever mortality is to root out of stations, and of all places frequented by the troops, the well-known local causes of these diseases, or as an alternative to keep the troops out of places where fevers are set up by bad sanitary conditions.

32. As affecting the general health of the soldier at Indian stations, Mr. Hewlett insists on the importance of improving his habits, diet, abolishing the use of spirits as a drink, and similar measures. In fact, all form part of the same precautionary system, and their object is to introduce the soldier by degrees and with due care to the great constitutional changes which must be undergone by rapid change of climate, and by the duties and habits of Indian military life.

Lastly, it would be out of place to go further into details, as these have been fully dealt with in the Government Resolution, and in the accompanying letters of the Quartermaster-General and Surgeon-General. It is most satisfactory to see that the importance of the whole question of these fevers in their relation to the sanitary condition of stations, and to the habits of the men, is fully realised by all parties, and that Mr. Hewlett's Report has been warmly appreciated, and not more than it deserves, by the executive authorities, to whom will now appertain the duty of giving practical effect to the necessary sanitary works and measures.

12th September 1884.

No. 18.

Memorandum of the Army Sanitary Commission on Report of Special Committee of Inquiry into the History of Cholera in India, 1862 to 1881, with reference to Cholera in the Punjab during the latter year.

1. On 19th September 1881 the Government of India appointed a Special Committee, consisting of Colonel C. A. Hall, President; Lieut.-Colonel Stevens, and Major King-Harman, members, and Surgeon-Major H. W. Bellew, C.S.I., member and secretary, "to inquire into the recent prevalence of cholera in certain portions of the Punjab." The Committee was left to determine the localities, but the Government directed their attention in the first instance to Lahore, Murree, Delhi, Umballa, Jullunder, and Sealkote. They were to collate the history of cholera in India during the last few years with that of the Punjab. They were to give details for each district, including the sanitary and other local conditions of the districts submitted to examination, and to compare the local conditions of affected localities with those of localities which had escaped the epidemic, including under this head the meteorology of districts.

They were to follow the same line of investigation in dealing with military stations and troops.

"Having carefully examined and recorded all the facts," the committee was instructed to draw the general conclusions "which these facts appear to warrant," to avoid all theoretical discussions, and to make such recommendations as seem best to them for the prevention of the disease in future years, both among the people generally and among the troops, and for the mitigation of outbreaks when they occur. . . . The report should be as concise as possible," and was to be illustrated with rough charts.

2. Looking at these instructions from our own point of view, we should have considered them as of a purely practical nature, with the intended object of making any addition which might appear as the result of local inquiry to procedure hitherto accepted and followed in the Punjab during epidemic periods. We should certainly not have so interpreted them as including within their sphere anything like an inquiry into the whole statistical history of cholera, and its relation to rainfall over India, still less so into collecting every local story about cholera contagion, which might have come before them. The Government of India has, however, disposed of this mistaken view, in such a way as to render any further notice of it unnecessary, for in their Resolution on the Committee's report, they say: "The President appears to have approached the inquiry with his mind made up to a theory of cholera "contagion, from which all other members of the committee eventually dissented. The consequence "of this has been that the witnesses were not subjected to any sufficient cross-examination, and their "statements have, in many instances, not been properly tested or analysed, while the so-called sum-"maries of evidence prepared by Colonel Hall are practically little more than the expression of his "own inferences, and are declared by his colleagues in almost every instance to be at variance "with the conclusion at which they had arrived, and to be insufficiently supported by the facts before "them."

3. It is no part of our duty to discuss the abstract question of cholera contagion, but in the presence of this decision of the Government of India, we think it right to call attention to the influence which this doctrine has exercised in India as elsewhere, in interfering with the advance of sound sanitary investigation, and also with sanitary work. It almost appears as if "contagion" and "local cause" were two principles of action diametrically opposed to each other, and we do know that they lead to quite opposite methods of dealing with epidemics, and this in face of the long-continued experience that procedure founded on the contagion doctrine has never in India led to the arrest of epidemic advance for one hour, while local sanitary work has, as a matter of experience, mitigated or prevented the incidence of disease during epidemic periods. The final decision of the Government of India on this part of the inquiry and report is stated as follows: "Under these circumstances, the Governor "General in Council considers that it would be mere waste of public money to print the voluminous "record of the local inquiries made by the Committee. It is much to be regretted that the course of "action adopted by Colonel Hall, as President, has rendered fruitless what might have been a very interesting and useful investigation."

Such being the case, we must confine our remarks solely to the part of the Report which has been been printed, and we cannot of course deal in any way with the unpublished portion of it.

4. The Report is described by the Special Committee, in their letter transmitting it to the Government of India as follows: "Our Report consists of three sections. The first section contains the "record of the investigations made at the several stations which were visited by the Special Com-"mittee. The second section consists of the history of cholera in India from 1862 to 1881. The "third section contains a statement of the practical measures we recommend for the prevention or "mitigation of the disease in future years."

For reasons stated by the Government of India, the first section could not be printed. Of the second section the only portion which has been printed is that which relates to the statistical history of cholera in the Punjab, but the topographical and meteorological data appear to have been left out from want of time. Similar data have been prepared in manuscript for all the provinces of India, and these were nearly ready for the press. The Punjab data are followed by a summary of the statistical history of cholera for the whole of India, together with the inductions drawn from the facts, prepared by Deputy Surgeon-General Bellew, the Sanitary Commissioner for the Punjab.

The entire second part is included in one volume, and the third part, which contains the recommendations of the Committee, occupies three folio pages of type.

The Punjab data occupy 216 quarto pages of type, Mr. Bellew's summary 135 pages, making together a volume of 351 closely printed pages, and from this fact we may perhaps estimate not only the great extent of the work done, but the size of the Report if the whole had been printed.

It cannot be said that there is much original matter in this Report. It is mainly collected from documents already printed, and the Punjab data may be useful for reference if so required. Mr. Bellew's summary, however, possesses considerable interest as a contribution to cholera history, partly as a continuation of the important work of the late Dr. Bryden, and partly because it contains etiological views of its author which we shall notice.

5. It is scarcely necessary to discuss the statistical histories, as we have dealt with these for each province year after year in previous Memoranda, and, besides this, the questions at issue are purely local questions, on which the general statistical history can throw no light except as to comparative intensity and periods of cholera prevalence, and the relation of these to epidemic movement, points which are of most importance in the cholera history of a specific year.

Such being the case, we shall limit our remarks as much as possible to any practical results which present themselves in those portions of the Report now before us in type.

6. The following is the definition of cholera adopted by the Committee as their groundwork: "The train of special symptoms may be broadly expressed as consisting of more or less sudden and "violent vomiting and purging of what are called rice water evacuations, followed quickly by collapse "and suppression of urine, which may speedily produce death or may terminate in recovery."

This definition excludes a vast number of milder diarrhœal cases, which precede and accompany all epidemics of cholera, but the object in adopting it appears to have been to confine the discussion as nearly as possible to that form or stage of the disease which approximates most nearly to death, which last is the only condition dealt with in the statistics.

The next point discussed by the Committee is an important one, namely, whether any of the popular theories of cholera can account for or be made to include the facts brought out in this voluminous inquiry. Their answer under each head is as follows:—

7. *The blood poison theory.*—"The existence of such a poison not having been ascertained to be a "fact, the belief in a primary blood poison in cholera has made no advance, but tends rather to be "superseded by other and more plausible explanations."

8. *The cholera contagion theory.*—"This theory asserts that some part of India is the native seat of "the origin and the prime centre of the diffusion of cholera, and that this diffusion of cholera is "effected by human agency, either in the bodies of individuals who have been exposed to the influence "of the disease, whether personally affected by it or not, or in the articles of their clothing, or "luggage, or merchandise, under certain conditions of their contamination by the material of cholera "discharges." After citing the momentous conclusions of the Constantinople Conference based on this theory, the Committee say, "The validity of these conclusions is not supported by our experience "of the behaviour of cholera in India, and the belief in the contagion of the disease, which has never "been generally held in those parts of the country in which cholera is a constant visitor, is now fast "disappearing in most parts of the country. The experience of every day in India, as is amply "illustrated in the following history of the behaviour of the disease year by year, very clearly teaches "that outbreaks of cholera do not travel in all directions as human beings do," and with reference to the exportation of cholera from India, they say, "There is the patent fact that the enormously "increased sea traffic betweeen India and the countries of Europe, since the opening of the Suez "Canal, has been followed by no commensurate increase of epidemic cholera in those countries."

9. *The water contamination theory.*—This is known as Dr. Snow's theory, and was promulgated in London in 1848, at a time when the water-supply was loudly complained of. "This theory asserts "the propagation of cholera by means of drinking water which has been contaminated by the matter "of cholera evacuations. . . . This theory, though long since considered untenable in England, "still has many advocates, and in India is about the most popular of all the theories which have been "hitherto enunciated to explain the appearance and spread of cholera, and yet it is apparently the "least tenable of them all. . . . . In India the water of streams, of tanks, and of wells, is "there is no manner of doubt, contaminated to a great extent by a variety of impurities, cholera "discharges amoug the number, more especially wherever man is settled in large communities with a "fixed residence. But this impurity of the water used for drinking purposes has not been found to "produce cholera. Although it is often enough one of the most prominent of the insanitary conditions "which are found to be present in places where cholera is prevalent, it is immeasurably more often "found to be present in places where no cholera prevails, the two classes of places being in many "places either contiguous or in close proximity in one and the same locality, but in the majority of "instances widely separated and in different localities."

Cholera excreta, like other non-cholera impurities, may pollute the water-supply of a locality, "(*a*) by surface drainage after rains washing the matter of cholera discharges which have been thrown "upon the ground into neighbouring streams and tanks, and into wells which have open mouths "unprotected by a parapet; (*b*) by the wind carrying dried excreta in dust into the water sources; "(*c*) by washing clothes or throwing corpses into water sources."

But while admitting these sources of water contamination as possible, and also that impure drinking water "may favour the attack of cholera in the individual by injuriously affecting the standard of his general bodily health," they point out that cholera poisoned water can only come into operation "after the disease itself is established in its activity," and that the statistical history of cholera which has been the result of their inquiry proves that causes of this class would not account for the facts. "There is no evidence to show that impure drinking water has anywhere in this country originated "an attack of cholera, and far less developed an epidemic of the disease.

There is thus no proof from this extensive inquiry that impure water has exercised any specific influence in the production or propagation of cholera in India, although in India, as elsewhere, water containing animalized matter in a state of putrescence, whether proceeding from healthy or choleraic discharges, may act as a predisposing condition when cholera is present in a locality. Existing putrescence appears to be the element required, and not any supposed specific poison. Hence impure water sources might be innocuous if the decomposition of organic matter were complete, and only nitrates remained, but almost poisonous if drank while putrescence was in progress.

10. *The germ theory of cholera.*—"This theory assumes the existence of a specific cholera germ or "entity endowed with life, a living organism of the fungus kind, which, being swallowed in food or "water, becomes infinitely multiplied in the intestinal canal, and causes by its action the symptoms "which constitute cholera."

The primary source of the "cholera germ" has usually been considered to be the soil, where its production or increase was related to certain soil impurities and conditions of subsoil drainage, water level, aeration, &c. The "germ" must also be present. A modification of this view, but of a much more scientific character, was propounded by the late Dr. Bryden, who, from a very extensive and careful inquiry into cholera history and statistics, arrived at the conclusion that cholera miasm was allied in its course to malaria, and that, like malaria, if transported by winds from the place of its origin, it could not reproduce itself, but must become extinct after a specified time unless renewed in the same way.

The facts on which Dr. Bryden rested his view are patent in the statistical history of every epidemic, but if the ordinary "germ" idea were introduced, there would be at once a contradiction between the

theory and the facts, *i.e.*, that facts would indicate a certain very definite history, while the germ addition would render such a history untenable.

The "germ" idea is also an element in the question of cholera contagion, but it must never be forgotten that the existence of a specific cholera germ has never been proved, and that whether cholera is due to contagion is a question still undecided. Although the first part of the present Report was based in its deductions on the contagion views of the President of the Committee, the final judgment upon it pronounced by the Committee as a whole is as follows: "The spread of "cholera by infection must be looked upon as a very subordinate contingency concurrent with the "natural diffusion of the epidemic influence." So very subordinate is it that after experience on the largest scale conducted on the persons of attendants on cholera cases, even in cholera affected localities, we have been compelled to state that a well appointed cholera hospital is about the safest place to be in during an epidemic of cholera.*

11. The Committee having dismissed the various existing theories about cholera in order to examine the facts *de novo*, have fallen back, as Dr. Bryden did several years ago, on the statistics of the disease as the only basis on which such an inquiry could rest. It follows that, in their view, none of the theoretical doctrines which have from time to time found their entrance into medical literature afford a basis on which a history of cholera, or any consistent plans for mitigating or preventing outbreaks of the disease, the final object of their inquiry, could be erected.

12. The plan of inquiry followed by the Committee is thus described: "The statistics of the "cholera mortality of the civil population for the year are presented at the outset. These are "analysed and accompanied by such descriptive matter as we have considered useful in elucidating "the history of the disease; then are noticed the incidence of cholera among the troops, European "and Native, and the jail populations, and the review of the year is concluded with a brief descrip-"tion of its salient meteorological peculiarities, and a note on the nature of the food supply in respect "to cheapness or the reverse."

The rainfall is assumed, not as an index of any direct relation between cholera mortality and rainfall, "but as an index to the general character of the season, the rainfall being a fair guide to the prevailing temperature and atmospheric humidity of the several months of the year."

The data are contained in tabular statements and diagrams, with maps showing the cholera history of each year in the Punjab from 1862 to 1881.

They have been already published in the annual reports of the Sanitary Commissioner, but are now printed together, so as to give in one view the past cholera history in the Punjab among the civil population, British and Native troops, and the jail population; and, so far, the labour has been of use, and will save trouble to future inquiries, but, when we come to ask the question what the use of it all can be towards accomplishing the objects indicated by the instructions of the Government of India issued to the Committee, it is not so easy to give a reply. We have already noticed the chief statistical data in our memoranda on the Sanitary Commissioners' annual reports, and also the topographical and sanitary information about stations and population groups, and the only question which arises is, whether the data, taken as a whole, throw any additional light on the causes of liability to cholera of troops and civil population in the province.

13. The Committee have thrown the totals of the annual tables into summaries for the whole period, and, as these afford useful information on the law of cholera incidence in the Punjab, we shall give them in abstracts beginning with the monthly deaths from the disease for the years 1865 to 1881.

Population,—1868, 17,487,125; 1881, 18,786,107.

Monthly aggregate of Cholera Deaths, 1865 to 1881, viz., for 17 consecutive Years.

Months.	Deaths from Cholera.	
	Total.	Per cent.
January	743	0·67
February	514	0·46
March	705	0·63
April	7,570	6·82
May	19,475	17·55
June	16,288	16·48
July	15,888	14·32
August	21,083	19·05
September	16,870	15·20
October	7,564	6·9e
November	1,558	1·3e
December	577	0·52
Total	110,930	100·00

This abstract may be taken to represent generally the monthly law of cholera prevalence in the Punjab. May, June, July, August, and September are the months of greatest prevalence of the epidemic.

* See the facts stated in Memorandum No. 1 from Dr. Cuningham's report.

14. The next abstract gives the annual deaths and death-rates per 1,000 for the same 17 years, with the addition of 1882.

Years.	Cholera Deaths.	Death Ratio per 1,000.	Years.	Cholera Deaths.	Death Ratio per 1,000.
1865	3,310	0·22	1874	78	0·004
1866	1,051	0·06	1875	6,246	0·36
1867	73,146	2·25	1876	5,736	0·33
1868	532	0·03	1877	29	0·001
1869	9,258	0·53	1878	215	0·01
1870	469	0·03	1879	26,135	1·49
1871	369	0·02	1880	274	0·01
1872	8,727	0·50	1881	5,797	0·30
1873	148	0·01	1882	39	0·002

This table by itself fully justifies the committee in the course they have taken in setting aside all cholera theories, because these appear to have no relation to the facts. None of them throw the smallest light on the history as developed in this abstract, unless endless suppositions be resorted to in place of facts, a method of dealing with scientific questions leading to no reliable practical results.

15. We propose, in the next abstract, to show the distribution of cholera over the Punjab districts for 17 years.

Districts.	Population.	Aggregate (17 Years) Cholera Deaths.	
		Total.	Deaths per 1,000 for the Period.
Delhi	608,850	2,794	4·58
Gurgaon	696,646	5,695	8·18
Karnal	610,927	4,815	7·88
Hissar	484,681	7,497	10·98
Rohtak	536,959	3,440	6·40
Sirsa	210,795	2,489	11·09

The practical information afforded by this table is of interest and importance, for it shows that, for some cause or causes, climatic, topographical, or local, cholera is greatly more prevalent in some districts of the country than in others.

16. The same rule holds good as regards villages and towns. There are in the Punjab 268 towns and 34,973 villages, making together 35,181 population groups, and on a seven years' average, 1875 to 1881, the whole cholera mortality has been furnished by less than 2·9 per cent. of them on an annual average.

51

We have long since called attention to the fact that increase of cholera deaths in a district points to a larger per-centage of attacked villages, and to more deaths in those attacked. The severe epidemic of 1879 is a proof of this law of cholera, for the total sum of attacked villages in seven years was 6,022, and of these 3,753 local attacks were due to this one year's epidemic.

17. We shall next give the statistical history of cholera among European and native troops for a period of 20 years.

Years.	European Troops.				Native Troops.			
	Strength.	Admission.	Deaths.	Deaths per 1,000.	Strength.	Admission.	Deaths.	Deaths per 1,000.
1862	17,100	363	203	12·70	22,056	174	87	4·01

1873	16,629	1	—	—	25,825	3	—	—
1874	15,011	1	1	0·06	25,877	1	1	0·03
1875	14,591	36	44	3·01	25,892	60	26	1·00
1876	16,369	109	81	4·95	25,553	102	57	2·23
1877	15,856	1	—	—	26,447	—	—	—
1878	14,657	1	1	0·07	26,260	—	—	—
1879	14,294	293	227	15·88	19,355	121	75	3·87
1880	13,562	57	44	3·24	21,905	23	18	0·84
1881	15,251	111	82	5·38	29,526	21	11	0·37

By comparing the data in this abstract with those in the preceding table, showing the annual death-rates among the civil population, it will be evident that in all the cases the incidence of cholera follows the same epidemic law; hence we arrive at the conclusion that when cholera attacks stations of British and native regiments, it does so epidemically. The table also shows how greatly more prevalent and fatal cholera has been in times past among European than among native troops, and how largely the cholera death-rate among the former was raised by the Afghan war.

18. We have already given an abstract of the monthly incidence of cholera among the civil population of the Punjab for a period of 12 years, to which may be added, for the purpose of comparison, the following aggregate monthly admissions from cholera among European troops at Punjab stations for a period of 10 years, 1870–79, from Dr. Stephen's statistics:—

Months.	Admissions from Cholera.		Months.	Admissions from Cholera.	
	Total.	Per Cent. of Total.		Total.	Per Cent. of Total.
January	—	—	July	42	6·86
February	—	—	August	195	31·86
March	—	—	September	101	16·50
April	20	3·27	October	115	18·79
May	67	10·95	November	3	·49
June	69	11·28	December	—	—

On comparing the two tables, it will be seen that the monthly incidence of cholera follows the same rule among troops as among the town and village populations. Both classes escape, or nearly escape, cholera during four months of each year, January, February, March, and December. Epidemics set in with the month of April in both cases, and cease or nearly cease in November. The month of maximum prevalence is August. Thus we learn that European troops at Punjab stations are under the same laws of epidemic cholera, whether as regards the annual intensity of cholera or its monthly prevalence, as are the civil groups of population in towns and villages.

19. The next subject of inquiry is the relative prevalence of cholera at each station of European troops in the Punjab, and for this purpose we shall use the 10 years' data, 1870–79, in Dr. Stephen's statistics, as follows:—

AGGREGATE STRENGTHS and AGGREGATE MONTHLY CHOLERA DEATHS at each STATION of EUROPEAN TROOPS in the PUNJAB from 1870 to 1879.

Stations.	Aggregate 10 Years' Strength.	Aggregate Monthly Cholera Deaths.												Deaths per 1,000 Average Strength.
		January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.

During the years 1870—1879 the only hill stations in the Punjab which escaped cholera were Ranikhet, Jutogh, and Dalhousie, and this table shows exactly the relative liability to attacks of cholera at all other Punjab stations. It will be seen that the hill stations conform to the same epidemic rule as to times of cholera prevalence as stations on the plains.

The facts would show that the whole area of the Punjab, including its hills and mountain groups, is influenced by the same epidemic condition of cholera at the same periods of time, and hence the next matter for inquiry is, why the middle and later months are so peculiarly liable to epidemic outbreaks of the disease. Certain of the conditions, such as the sites of stations, troops, general sanitary arrangements, water-supply, remain the same throughout the year, and the only variable conditions are those connected with climate, including under this head temperature, temperature ranges, moisture, winds, their strength and direction, and rainfall, the last including in it the relation of the amount and distribution of rain to drainages of areas and subsoil water-level and dampness of locality. Local dampness of soil and atmosphere, high temperature, and stillness of atmosphere, favour rapid decomposition of all organic matters, and tend to make the air impure, and the Punjab itself has afforded striking illustrations of the connexion of these conditions with cholera outbreaks, as well as of their cessation when great atmospheric movements had taken place.

20. In their Report the special committee have given abstracts of some climatic elements which admit of being used in a very general way, in the relation to the total monthly deaths from cholera, and we shall here tabulate them, to show whether any and what relation exists between these death-rates and the rainfall. As some of the data are taken from Dr. Stephen's 10 years' statistics, we shall assume a 10 years' period as affording sufficient data for our object, and place side by side the death-rates of civil population and European troops, with the annual rainfall.

Years.	Death-rates per 1,000,		Rainfall.
	Civil Population.	European Troops.	
			Inches.
1870 - - -	0·08	—	20·14

1879 - - -	1·49	15·88	23·56

It would appear from this table that the average annual rainfall has no very marked relation to the cholera death-rate either among the civil population or European troops. It cannot be said that a small annual fall is attended by a higher cholera death-rate, or the contrary. There are apparent exceptions on both sides, but, looking at the facts as a whole, we may conclude that the actual amount of rain falling in a year, without reference to its distribution and to other meteorological elements, does not afford us any help in tracing the determining causes of cholera epidemics in the Punjab.

21. We shall next inquire whether the rain distribution affords any light on the subject, and for this purpose we shall place side by side the three following elements,—1st, the monthly per-centage of annual cholera deaths among the civil population; 2nd, the same data for troops, using, however, in this latter case, the monthly cholera admissions for 10 years, 1870—1879; 3rd, the monthly per-centage of the 10 years' average rainfall.

Months.	Average per-centage of Cholera mortality among the Civil Population.	Average per-centage of Cholera admissions among European Troops.	Average Monthly per-centage of Rainfall.
January	0·67	—	3·5
February	0·46	—	5·3

December	0·52	—	3·1
	100·00	100·00	100·00

This abstract shows that the average monthly distribution of rain has an apparent relation to the monthly prevalence of cholera, but the comparative quiescence of cholera in the first three months of the year, notwithstanding the fall of a measurable per-centage of rain, would appear to show that lower temperature exerted a certain restraining influence on the disease. On and after April, however, increase of rain is attended with a very decided increase of cholera up to September, after which both decline. It would almost appear as if the cholera cycle was made up of two epochs, one beginning in April and ending in September, and the other lasting thenceforth until April of the following year. During the first, rise of temperature and of rainfall co-exist, and during the second, low rainfall and lower and more variable temperatures accompany decline of cholera.

These results are of course deduced from averages, extending over the whole country; but, in order to appreciate the influence of local climates on cholera prevalence, we shall select two or three of the more important stations of European troops to show this fact, and use the data for 1881, which were the ground of the present inquiry.

Lahore and Meean Meer, 1881.

	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
Mean temperature	55·8	63·9	66·9	81·6	90·4	95·5	88·3	85·5	87·0	79·4	64·1	57·6
Daily temperature range	30·7	26·5	21·7	25·7	30·2	24·	15·9	14·2	22·0	30·5	34·3	31·2
Rainfall	0·63	1·31	2·35	0·57	0·95	0·41	12·39	8·05	0·18	0·12	—	—
Humidity	54	55	64	43	38	44	69	79	59	50	50	53
Cholera deaths, Lahore district	—	—	2	—	2	51	104	318	590	71	5	—
Cholera admissions at Meean Meer and Fort Lahore (strength 1,127).	—	—	—	—	1	44	14	34	—	—	2	—

The results of this table are interesting, for they show that cholera was dormant in the district and military station when temperature and rainfall were low, although the daily ranges of temperature were high. Also that high temperature, with increase of rain, acted rapidly on the amount of cholera, both at the station and among the civil population, although the temperature ranges were not extreme, and that cholera again became dormant with falling temperature and disappearance of rain. Air humidity, although greatest in July and August, when cholera was most fatal, showed a less marked coincidence with cholera mortality than did rain.

22. If we compare the rainfall and cholera mortality of 1881 with the same data for 1880, we obtain the following confirmatory facts showing the relation of rain to cholera. In the former year there were 1,643 deaths from cholera in Lahore district, and 71 at Meean Meer and Fort Lahore, in all 1,714 deaths. The rainfall was 26·38 inches, which was 5·18 inches above the average. In 1880 the deaths from cholera in Lahore district were only 14, and there was not a single case of cholera among European troops, either at Meean Meer or Fort Lahore. The rainfall in 1880, was only 11·27 inches. A striking illustration of low cholera mortality and low rainfall is afforded by Mooltan, which has been always remarkable for its comparative exemption from this disease. We have already shown that out of an average population in this district of 459,765, there had been 678 cholera deaths in 17 years, equal to a death-rate of 1·45 per 1,000 for the period, or 0·085 per 1,000 annually. In 1881 Mooltan did not yield a single cholera death among the civil population, nor a single case among European troops. Now the average rainfall at Mooltan is only 7·17 inches, and in 1881 it had fallen to 4·27 inches.

One other example may be adduced to show that something besides the amount of rain enters as a factor in the determining causes of cholera mortality. The case is Peshawar, which, as we have shown, is one of the most severely affected districts in the Punjab, and indeed in all India. Its aggregate cholera death-rate, for a period of 17 years, has been 14·33 per 1,000 of its district population, and 11·26 per 1,000 per annum among European troops, yet its average rainfall is only 14·35 inches per annum. In 1881 the rainfall was 15·90 inches, an increase of about an inch and a half. But there were only three deaths from cholera among the civil population, and not a single case among European troops in that year.

23. We would not infer from these facts that rainfall has no relation to cholera mortality, for it has been long known that under certain local and climatic conditions a heavy rain will wash out cholera as effectually as it cleanses foul street gutters and sewers, and provides purer water. And in the same way deficiency or absence of rain, with active evaporation, may lead to all local filth causes becoming aggravated, and well waters more impure. But suppose we have an area of ground covered with barracks or houses, which have been allowed to become fouled, or suppose a barrack or camp is placed on foul ground, this question presents itself,—What is likely to be the effect on such a locality of a few moderate showers of rain, no more than sufficient in a warm climate to wet or damp the ground to a few feet from the surface? There can be but one answer; it simply adds the element required to stir up all putrefactive processes into greater activity. Is there no smell, for example, at Meean Meer after rain? And is the site, with its past history of long occupation by native troops before it became a European station, a likely one to escape mischief under certain conditions of rainfall temperature and moisture? We answer that the cholera statistics already given show its precise value in relation to the health of troops.

24. It will be seen that in our view climatic elements in their bearing on cholera prevalence require to be studied with reference to the locality itself, and that climate and its influence cannot be estimated merely from meteorological records. These are invaluable, as containing facts, but not as recording efficient causes of cholera. They afford great help in carrying out local inquiries, especially in warm climates, and ought to be so used. But this is all.

25. There is another point as regards rainfall, besides its local influence on health, which must be taken into account, and this is its effect on food prices during the year, for these have an influence on the susceptibility of the people to epidemics of all kinds, but it cannot be said that deficiency of food is an efficient cause of cholera. The epidemic must be there before starved people can suffer.

26. We have entered on this discussion about climate on account of the prominence given to it in the present Report. Most of the remaining paragraphs are taken up with local cholera history, much of which had been published before in reports of Sanitary Commissioners. They have a certain importance in local epidemiological history, and might be useful in such inquiries, but when we ask the question as to the amount of light they throw on the local etiology of cholera, and what lessons of a practical kind for saving life can be drawn from them, we would, in view of the great labour which has been spent over the details, prefer to express regret that their practical results in this direction have not been deduced by the committee.

27. A similar remark may be made regarding the laborious and interesting extension of Dr. Bryden's inquiry on the general and annual history of Indian cholera by the Sanitary Commissioner of the Punjab, which forms the second part of the volume. In our view, the Government of India has conferred a benefit on civil and military medical officers, by resolving to circulate it among them. It cannot be said that there is anything absolutely new in it, but Mr. Bellew has given in a comparatively brief space the results of many years of local inquiry and observation, all over India, into the statistical history of cholera and its relation to rainfall and food supply. But still the question of local etiology is left unsolved.

It is not that this important question has been ignored, because the Report itself acknowledges the successive diminution of cholera deaths in the Punjab alongside successive advances of sanitary improvements in cities and towns; and the Sanitary Commissioner has, moreover, in his official capacity, given ample proof of his estimate of the paramount necessity of pressing forwards with sanitary work. Our remark applies to the position which local sanitary condition occupies in the Report.

28. The most interesting part of the volume is Part II. of Mr. Bellew's summary, namely, the "deductions drawn from the general statistical summary, together with practical observations regarding the nature and causes of cholera."

The result is not a new theory about cholera so much as a pathology different from the one at present received. The questions raised relate to medical inquiry rather than to sanitary practice, and appear to have assumed their form from certain pre-occupations arising from too great importance being attributed to meteorology in the chain of events. Such a discussion is perfectly legitimate, and may do good by freeing the minds of medical officers from views of a less tenable character, and weakening the influence of one-sided doctrines about this disease.

29. Resting on the known result that statistics of cholera mortality do not convey a correct idea of the prevalence of an epidemic, Mr. Bellew says that this is due to the fact "that cholera is rarely "recognised, or acknowledged as such, until some case ends fatally with suddenness and violence of "symptoms, or until the disease breaks out into epidemic activity, and even then the milder attacks, "although they may prove fatal, occurring at the same time and in the same locality, are rarely, if "ever, recognised as in any way connected therewith. In fact, the malady which is produced by the "cholera influence is not sufficiently recognised as cholera either by the profession or by laymen, "until or unless it manifests the grave symptoms characteristic of the last or most fatal stage of the "severer forms frequently assumed by the disease; whereas, as a matter of fact, and more especially "in seasons of its epidemic prevalence, cholera affects in a mild or moderate degree of severity a "vastly greater number than it kills by the violence of its assaults. . . . . The records, however, "so far as they go, show that cholera in India is a disease, which, in point of prevalence, is very "intimately related to and dependent upon the climatic and seasonal influences of the country both "as a whole and as made up of constituent parts; and further that the effects of these climatic and "seasonal influences, as manifested by the prevalence and fatality of the disease, are in a very "remarkable manner modified and controlled by conditions of locality affecting the soil, the weather, "and the life circumstances of the people."

This view of cholera and its universality is not a new one. It has, on the contrary, been held by some physicians that wherever there is diarrhœa there is cholera, ready to assume its most fatal aspect whenever the required conditions are present. Mr. Bellew discusses the question at considerable length, but it lies beyond our immediate object, except in so far as the practical result is concerned. After deducing the relation of meteorological data to the disease, and showing in this connexion that all the stages from diarrhœa onwards come under the same law of a three years' period, he condemns the usual separation of the last and fatal stage from the general body of the disease, because this view leads to neglect of treatment at the only curable stage, and results in the belief that the severer forms constitute a contagious disease, than which, he says, "no more mischievous practice could be followed." By neglect of the earlier stages "the patient is allowed to drift into a stage of the disease in which treatment by medicine is impotent." While the contagion doctrine applied to the later stages of the disease leads to the result that "an amount of injury and "vexation is caused which has not unfrequently given rise to the expression that the cholera is less "to be dreaded than the doctor." He condemns the precautions usually adopted as "absurd and contradictory;" and, further, he says that "in every outbreak of epidemic cholera, much mistrust and "discontent are produced amongst the people, by our inconsistent measures of medical treatment "and preventive precaution." Amongst other measures of the latter class he condemns the contagion theory practice of destroying by fire the bedding and property of patients without such compensation as the sufferers deem adequate. All these customary quarantine precautions might possibly be justifiable if any proof could be adduced that they had been of the least value. Such proof, however, is totally wanting; and, moreover, if cholera is an epidemic and not merely a stage of an epidemic, such proof can never be obtained, as the whole previous course of the disease has been overlooked.

30. "What then is cholera?" This question, posed anew by the Sanitary Commissioner, is replied to by him as follows. After citing his experience of cholera in England, Turkey, Bengal, and the Punjab, and his acquaintance with the statistics of Indian cholera, and its literature, he says: —"Cholera is simply an influenza or catarrh of the mucous membrane of the alimentary canal, "precisely homologous to the influenza or catarrh of the mucous membrane of the respiratory "passages; and, further, we believe, from an extended, practical, and personal experience of the "maladies now coming under consideration, that the two above-mentioned different forms of influenza "or catarrh are intimately related to a still more different form of the same disease as represented "by the train of symptoms which characterize what are commonly known as malarious fevers, whether "of the intermittent, remittent, or continued forms, and that they are all dependent for their "production upon peculiar conditions of the weather, aided by those of soil and locality, as the exciting "causes, and upon certain conditions of the individual health as the predisposing causes." This view of the nature of cholera and its alliances is fully discussed; but the general conclusion, so far as cholera is concerned, is, that "cholera in India, at all events, is a disease which is entirely "dependent for its origin upon the effects of atmospheric influences acting upon the body through "the skin and lungs, as in the other malarial fevers we have enumerated, modified and controlled no "doubt by the health state of the individual, and the immediately predisposing cause of the attack, "and controlled in respect to mildness or severity of prevalence by peculiarities of epidemic "season."

31. As our present object is to see whether the Report under review throws any new light on means of protecting the health of the troops in the Punjab, it may be well before proceeding further,

To introduce the following data, showing the relation between the monthly per-centages of the annual rainfall and the monthly per-centages of annual admissions among European troops in this province, during a period of 10 years, from the more important diseases:—

Months.	Monthly Per-centage of Rainfall, 1870–1879.	Monthly Per-centages of Admissions from Epidemics among European Troops, 1870–1879.				
		Cholera.	Enteric Fever.	Intermittent Fever.	Remittent and Continued Fever.	All Causes.
January	3·5	—	4·	5·2	1·3	6·1
February	5·3	—	4·	3·6	1·4	5·1
March	4·3	—	4·	3·3	2·0	5·3
April	3·0	3·3	8·	3·9	6·1	6·5
May	4·2	11·5	16·	5·1	13·8	8·1

July	27·2	5·5	12·	6·4	18·4	8·9
August	25·0	32·88	8·	8·1	13·1	9·5
September	11·8	16·40	10·	14·4	16·3	11·8
October	1·8	18·00	8·	19·2	12·6	12·8
November	1·1	—	4·	15·7	5·2	10·3
December	3·1	—	4·	9·4	2·5	7·7

In order to understand this table, the following totals may be here introduced. European troops in the Punjab, 1870–79; aggregates, 10 years:—

Strength	112,288
Admissions, all causes	207,421
Deaths, all causes	2,326
Cholera admissions	612
„ deaths	444
Enteric fever admissions	536
„ „ deaths	260
Intermittent fever admissions	76,981
„ „ deaths	29
Remittent and continued fever admissions	31,358
„ „ „ deaths	223

These aggregates include the sanitary problems presented by stations of European troops in the Punjab, and by referring to the preceding admission ratios, it will be seen that the more fatal diseases have all an apparent relation to the monthly rainfall. This relation is marked as regards cholera, enteric fever, and remittent and continued fevers. Intermittent fever, on the contrary, increases after the rainfall and during the drying up and variable temperature months. Admissions from "all causes" increase with falling off of rain, a fact which is explained by the very great proportion of admissions from intermittent fever, which considerably exceeded a third of the total 10 years' admissions. It is hence quite clear that the relation of rainfall to this fever is not the same relation as it bears to cholera, or to the more fatal fevers.

The average 10 years' rainfall was 27·62 inches, as the table shows that above 80 per cent. of it fell during the months of prevalence of the more fatal diseases. The mere fall of 22 inches of rain in six months can scarcely be credited with such a result. There must have been some other causes let loose by the rain, and what these causes were, and how they can be dealt with, is precisely the sanitary problem presented by the rainfall at these stations.

32. What really was required in a practical sanitary inquiry, such as the present was intended to be, was that each station should have been taken separately, and an exhaustive inquiry carried out. This has not been done, and the only result is, that during months of maximum rainfall we may look for deaths from epidemic and endemic diseases. The facts which we have abstracted from Dr. Stephen's tables show this clearly enough, but it is precisely at this point that sanitary investigation ought to begin.

The causes to be dealt with cannot be arrived at by any general assumptions such as those involved in the statement that to sanitary precautions "belong all the multifarious details connected with conservancy, ventilation, space, diet, clothing, shelter, occupation, and habits." Even if all this were done for all the stations we should still be without information as to the reasons of great cholera mortality at such stations as Meean Meer, Peshawar, Murree, and the like.

33. A similar remark applies to the third part of the Report on the "Recommendations proposed by the committee for the future prevention of cholera," which we next proceed to discuss.

The first recommendation is one in regard to which there can be no difference of opinion, because [redacted] been all along recognised as necessary, and this is a pure water-supply for stations and their [redacted]uring towns.

[redacted]econd recommendation can scarcely be called a logical one. The committee are of opinion [redacted]thout going so far as to insist upon a general quarantine in all stations which are occupied [redacted] seasons of epidemic cholera, it is of the first importance that such bodies of men, as well as

" prisoners in jails, should be as much as possible prevented from coming in contact with the genera
" public, and they would therefore recommend that paragraph 78 of the rules laying down the measures
" to be adopted on an outbreak of cholera be cancelled, and that it be left discretionary with com-
" manding officers in communication with the civil authorities to enforce quarantine within cantonment
" limits, but that in respect to jails they would recommend that the order for quarantine be com-
" pulsory." Such a proposal as this scarcely admits of discussion. Are the lives of prisoners of more importance to the State than the lives of troops or the lives of the civil population?

If the committee have arrived at the conclusion that quarantine can arrest cholera, why not state the facts on which their opinion is founded? and if these are such as to justify quarantine, by all means let it be adopted universally. But, as we have already stated, the Government of India has passed a sweeping condemnation on the whole contagion part of the inquiry, and quarantine as a preventive measure is out of court.

Curiously enough, there is one modification of interrupted intercourse which is of known efficacy, and the necessity for which is moreover shown by the data in the Report, of which no notice is taken, and this is preventing troops going into cholera-affected localities. The aggregate of evidence over all years included in the committee's Report shows that when cholera prevails in the Punjab, it does so by attacking local groups of population, and that of these groups no more than 2·9 per cent. have furnished the annual deaths. Now it is a known fact admitting of no dispute that healthy people going into an affected locality are peculiarly liable to attacks of cholera, but that if any attempt is made to prevent the people in such localities from leaving them, they in their turn will perish. What commanding officers have to do is simply to keep their men from visiting affected localities. There is absolutely no warrant for trusting to any other measure. The third recommendation applies to the inspection of articles of food, especially during epidemics. This is an old recommendation, and a very proper one. In the fourth recommendation the measures adopted for removing troops from stations are discussed, and the use of railways wherever practicable is advisable to avoid fatigue. In this view we concur, and perhaps it may be useful to state the general principles which in our view ought to regulate the removal of troops.

34. These are as follow:—The aggregate of evidence in the Report goes to prove that, while cholera, as an epidemic, is influenced in its course and history by climatic causes, its attacks are strictly determined by local and personal causes. So far is this the case that it might be possible to form a map for every station showing all the points, for many miles around it, where cholera is likely to be present or absent. In this way a neutral zone might possibly be found, within which troops might be safely placed during epidemics.

Next, every station should be supplied, by telegraph or otherwise, with information as to position and advance of cholera at fixed dates. We have already seen that Punjab stations are quite safe from cholera during January, February, and March, and that necessity for removal does not arise until April, when cholera first appears, but that preparations ought then to be made for the outburst of cholera in May, during which month troops should be removed from Peshawar, Meean Meer, and Murree more particularly. A cardinal point to bear in mind is, that when cholera attacks a station, the station has become an affected locality, and that many more men are under the cholera influence than the number which has been attacked. These latent cases will become developed, whether left in the station or removed, although more may die if left at the station. The occurrence of cases after removal is no proof that removal has failed, but it is a decided proof that the removal has not taken place soon enough, and to men in such a condition fatigue would be injurious, and hence the recommendation of the committee as to using railway conveyance is in accord with the necessities, but the facts also show that it would be better to settle the cases in which removal should take place in April, for May is a distinctly epidemic month, when removal might be too late to save life. In all cases care should be taken to avoid fatigue, and not to expose the troops to wet.

35. The fifth recommendation is an important one regarding better dieting of troops. We have often insisted on this point, and we concur in the general principle laid down by the committee, leaving the details to the authorities in each Government.

36. Besides the recommendations, the committee insist on the relation of dear food to cholera mortality, and they admit the great difficulty of dealing with this aspect of the question. The greatest mortality, they state, occurs more especially among the poorer Mahomedans, "who, for the most part, lived in wretched hovels, poorly clad and ill-fed." This is no doubt true; but, if we cannot clothe and feed the people, we can do something towards improving their surroundings, and the committee fully admit the importance of "the recognized branches of public sanitation, such as drainage, sewerage, conservancy, ventilation, housing," and they conclude by expressing an opinion that, in these sanitary matters, "the system on which the Government has been working for so " many years is an excellent one, and it only remains now for it to be carried out to the fullest " extent possible, and to ensure its efficient maintenance at all times."

37. Could not all this have been advised without a long and laborious investigation, and have the results thrown any new light at all on the great liability of British troops at Punjab stations to attacks of cholera, notwithstanding plenty of food?

38. It would be out of place to make recommendations on the conduct of a finished inqu
perhaps we may be permitted to suggest that, when another opportunity occurs, some light
obtained on this subject if, besides inquiry into general climatic influences and the relati
monsoons to cholera advance and prevalence, further local inquiries were carried out as to

influence of local topography on local climates. Such, for example, as takes place in the case of Murree, or at Peshawar, from its peculiar local position, or at Meean Meer, from stillness of atmosphere. It is possible that slowly-moving masses of air during cholera seasons, or absence of movement, may exert considerable influence on outbreaks of cholera. Hence the importance of paying great attention to the direction and force of winds and prevalence of calms during cholera seasons. Again, the relation of surface and subsoil configuration to rainfall merits minute inquiry. Why, for instance, are some parts of stations more unhealthy than others, and even some buildings than others? Are there impervious beds of clay or kunkur under the buildings, at such a depth or with such configuration as to retain water after rain? Or are the affected localities so situated that infiltration and retention of canal water may lead to similar results? It may happen that drainage of depressions or impervious beds may in some cases go far to remedy the evil.

39. As regards personal hygiene of troops, it may be suggested whether further inquiry might not be made as to the effect of night duty in predisposing men to cholera at the more severely affected stations, or living in common barrack-rooms instead of in separate houses, as in the case with native troops, who suffer so much less from cholera than European troops do. The frequent occurrence of cholera in particular buildings and hospitals would appear to point to the advantage of occasional evacuation of hospital buildings and barrack blocks.

These points are merely suggested as among those which might possibly lead us to some practical results in dealing with cholera in the Punjab. It is not unlikely that many others might present themselves on the spot, but we are obliged to deal with the question generally, as it has come before us.

We have alluded to the advantage of telegraphic communication between stations and affected districts when cholera is moving. This is a matter of considerable importance in enabling conclusions to be arrived at as to direction and times of cholera invasion and the movement of troops; but besides this, the telegraph, if properly used, would convey facts, and enable them to be recorded at the time, of the greatest importance to the general history of cholera and the best means of meeting its advance.

40. In conclusion, in the absence of adequate local information about the more severely affected stations and localities in the Punjab, the practical result of this report is that Meean Meer, Peshawar, and Murree should cease to be occupied by British troops. But in questions of public health we are not disposed to accept such conclusions without knowing the reason why, and this is precisely what the inquiry has failed in. One result of it, however, has been to show the paramount necessity of timely information of the movement of cholera being available, and of timely steps being adopted for removing troops out of these stations. We may repeat what we have said, that, as a contribution to the study of Indian cholera, especially in its relation to certain elements of climate, and the influences of these on cholera, the committee has collected much useful information, but as regards the far more important question why stations and population groups in the Punjab suffer so severely from cholera, and why certain of them yield higher death-rates than others, our knowledge is just where it was.

No. 19.

[redacted] Army Sanitary Commission on Papers referring to Fairs and [redacted] in Madras Presidency in the latter part of 1882 and in 1883.

[redacted]tain brief notices of 26 festivals and fairs held in various districts in Madras [redacted]f 1882 and October 1883, but only five of them took place in the former year. [redacted]ending are given in 16 instances, and they amounted in all to above 300,000. The [redacted]ce was 100,000 at Conjeveram. All the fairs were free from cholera except two, [redacted]festival at Srirangam and the Tirupati festival, which again yielded a few cholera

[redacted]angam case, cholera was present in the town when the people assembled, and there [redacted] and 13 deaths among the townspeople. The pilgrims had four cases, of which two [redacted]t of 12,000 people at the fair. It was an instance of persons coming in numbers into [redacted]lity, which is always a dangerous proceeding.

[redacted]upati case some sanitary improvement had taken place in conservancy, water, and food. [redacted]ot the cholera history as yet of October 1883, so that no connexion can be traced with [redacted] epidemic history, if any such existed; but with the facts about Upper Tirupati during [redacted] cholera outbreak there, we think it doubtful whether every disease cause then brought [redacted]d been removed.

[redacted]irs the sanitary arrangements are stated to have been sufficient. In the remaining cases [redacted]ty was required. In the same way the water-supply at 19 fairs is favourably reported on, [redacted]remaining cases not so.

The practical result of the year's experience has been that cholera was a very unimportant element in the health history of these fairs, and this great improvement is only a continuation of the annual record of these festivals since sanitary work was first relied on for protection from cholera amongst the people assembled at them. Much good work appears to have been done in the way of prevention, but, on the other hand, we have no information about the outside history of cholera, except in one or two cases.

The lesson *taught* by these reports is the same as the one we have endeavoured to enforce from the experience of previous years, namely, that the only known *method* of protecting festivals and fairs from cholera is systematic preparation of the sites to be occupied before the people arrive, and rigid enforcement of cleanliness and protection of water sources during the time of the festivals. Any return to the old negligence in these matters will very soon show itself in the cholera statistics.

REPORT.

I.—EUROPEAN ARMY OF INDIA.

Sickness and mortality in 1883.

THE health statistics of the European Army in India for 1883 are, as a whole, most satisfactory, and show a further improvement on the favourable results of the previous year. Of an average strength of 55,525, according to the Report of the Sanitary Commissioner with the Government of India, the admissions to hospital in 1883 equalled 1,336 per 1,000 against 1,445 in 1882, the daily sick 63 per 1,000 against 65, and the mortality 10·88 per 1,000 against 12·07. In all respects the results compare favourably with those of the five previous years, while the death-rate was the lowest on record, and fell short of the average of the 10-year period, 1870–79, by 8·46 per 1,000.

The following statement gives the relative extent of the sickness and mortality among European troops in the three Presidencies for 1883, and the previous year:—

Presidency.		Average Strength.	Ratio per 1,000 of Average Strength.		
			Admissions into Hospitals.	Daily Sick.	Deaths.
Bengal	1882	35,164	1,579	69	13·17
	1883	34,079	1,463	66	12·21
Madras	1882	11,020	1,058	57	10·23
	1883	10,498	1,013	59	10·19
Bombay	1882	11,085	1,405	61	10·57
	1883	10,948	1,249	57	10·50
India	1882	57,269	1,445	65	12·07
	1883	55,525	1,336	63	10·88

It will be seen from the above that there was a marked improvement in the health of the Bengal army. The mortality was lowest in the Madras army, and was almost identical with that of 1880 (10·18), the lowest on record. In the Bombay army there was less sickness, with a trifling increase in mortality, which was entirely due to cholera; deducting the deaths from this disease the death-rate for 1883 would stand at 9·68 against 9·74 in 1882. "The facts taken, as a whole," the Army Sanitary Commission observe, "appear "to justify an expression of opinion, that improved health is due to sanitary work at the "stations, and to better habits among the men, and improved administration generally."

Malarial fevers as usual were the chief causes of sickness in the European army, though the admissions were not so numerous as in 1882. The decrease was most marked in Bengal where the ratio per 1,000 of strength fell from 660 in 1882 to 486; in the Madras army the admission-rate under this head was 128 per 1,000 against 171 in 1882; and in the Bombay army 436 against 558. Enteric fever was again the most fatal disease in all three Presidencies, and for the entire European army the death-rate from this cause was 3·40 per 1,000 of strength.

Of the six geographical groups into which the Bengal Presidency has been divided, four recorded a higher admission-rate than the average rate of the Presidency. These were the Punjab group, 1,601; Meerut and Rohilcund, 1,528; Agra and Central India, 1,497; and the Gangetic Provinces and Oudh, 1,474. In the other two groups, the Hill stations recorded the unusually high rate of 1,454, and Bengal Proper, 1,011. Of the various diseases, fevers were most prevalent in the Punjab and Rohilcund with Meerut; dysentery and diarrhœa in Hill stations and Gangetic Provinces; respiratory diseases in Hill stations, Punjab, and Gangetic Provinces; and venereal diseases in Bengal Proper. As regards mortality, the highest ratio, 17·04, was recorded in the Gangetic Provinces, of which 3·92 was due to cholera and 3·17 to enteric fever; Agra and Central India followed with a death-rate of 14·27, enteric fever accounting for 4·26. But although the mortality in both these groups exceeded that of the other four, which ranged from 6·33 to 11·21 per 1,000, the ratios were lower than they had been in many previous years.

Among individual stations of the three Presidencies the average admission-rate for the whole army of India was exceeded in 39, Attock recording the highest, 3,390 per 1,000. Excluding this and other small stations with an average strength of less than 200 men, five stations recorded admission-rates of over 2,000, ranging from 3,032 per 1,000 in Amritsar to 2,563 in

Peshawar. The average mortality of the army of India was exceeded in 38 stations out of 92; and of those with an average strength exceeding 200 the highest death-rates were recorded at the following stations:—Benares 39·89 per 1,000, Gwalior Fort 34·97, Dinapore 26·82, Delhi 24·94, Shahjahanpur 23·81, and Kamptee 23·33. In Benares, Delhi, and Shahjahanpur there were no special causes to account for the high mortality; but in Gwalior 8 of the total 15 deaths were due to enteric fever, and 5 to cholera; in Dinapore 7 of the total 25 deaths were from cholera, and 7 from enteric fever; and in Kamptee 5 out of 14 deaths were from enteric and 3 from cholera.

The statistics of the Rajputana, Malwa, Sind, and Aden group of stations, belonging to the Bombay Command, were very favourable. Of an average strength of 4,687 the admissions were in the ratio of 1,502 per 1,000 against 1,745 in 1882, and the death-rate was 8·32 against 12·37. Mhow, which is the largest station of this group, was not so healthy as in 1882, the admission-rate having increased from 1,602 to 1,822 per 1,000, and the death-rate from 6·67 to 8·07. But the highest death-rates were recorded at the two stations of Indore and Karachi with Ghizree, viz., 17·39 and 16·34 respectively.

In the Deccan and Nagpur group of stations, also under the Bombay Command, the health of the European troops (average strength 6,694) in 1883 was not, on the whole, so satisfactory as in the previous year. The admissions declined from 1,029 per 1,000 in 1882 to 1,001, but the mortality rose from 7·94 to 10·72 per 1,000. Of the total admissions 265 per 1,000 were due to venereal diseases, while enteric fever and cholera were the chief causes of mortality, contributing 2·72 and 1·72 respectively to the total death-rate. This group comprises 11 stations, five of which recorded admission-rates exceeding the average; but at the two largest stations, Poona and Secunderabad, both sickness and mortality were much below the average rate of the group; the former yielded a death-rate of 8·33 per 1,000, and the latter 7·36. The highest mortality at any single station was 24·00 at Asirgarh, Kamptee following with 23·33, Kolhapur with 22·99, and Satara with 20·98. Excepting Kamptee, which had an average strength of 600, the other stations are all small, and a few deaths account for the large ratios.

In the seven stations comprising the Southern India group, with an average strength of 4,661, the admission-rate was 1,126, or 7 per 1,000 higher than in 1882; the death-rate was also slightly in excess of that of the previous year, 8·58 against 8·30. In this group also venereal diseases were the chief causes of admission (339 per 1,000), and wounds and accidents gave rise to a ratio of 128. More than half the mortality was due to enteric fever and hepatitis, the former yielding a death-rate of 3·44 and the latter of 1·72. Four of the stations recorded admission-rates of over 1,000; Bangalore, which is the largest station of the group, came first with 1,356 per 1,000; it also recorded the highest death-rate, viz., 11·53, which was almost identical with its average rate of 11·81 for the last decade. The next highest death-rates were 7·79 in Madras, 7·27 in Cannanore, and 7·11 at Bellary, all being considerably below the averages, especially Madras and Cannanore.

The statistics of the Burma and Pegu group of stations, four in number, compare favourably with those of the previous year. Of an average strength of 2,001 the admission-rate was 980 per 1,000 against 1,047 in 1882, and the mortality was 10 per 1,000 against 11·20. There were no deaths from cholera in this group; hepatitis was the chief death cause, contributing 2·50 of the total death-rate, dysentery and injuries following with death-rates of 1·00 per 1,000 each. Rangoon is the largest station in this group, and recorded the highest admission-rate of 1,304 per 1,000, towards which venereal diseases contributed 266, fevers 151, and dysentery and hepatitis 106 each. There were eight deaths in this station, equal to 10·91 per 1,000 of strength, half of which was due to hepatitis. Port Blair, a small station with an average strength of 140, recorded the highest death-rate (14·29); but only two deaths gave rise to this ratio.

The Hill stations of Madras and Bombay had an average strength of 811 men, among whom the admissions to hospital equalled 1,059 per 1,000 and the deaths 8·63, both being lower than in the previous year, and considerably below the average of the decade 1870–79.

Cholera.

As in the previous year there was very little cholera among the European troops in 1883, and the mortality it occasioned was pretty equally distributed over the three Presidency armies. In the army, as a whole, there were only 82 cases, and of these 51 or 0·92 per 1,000 of strength proved fatal. In 1882 there were 98 cases and 61 deaths or 1·07 per 1,000. Of the cases under treatment in 1883, the percentage of mortality was 62·20 against 62·24 in 1882. These favourable results were mainly due to the diminution of the disease in the Bengal portion of the army, in which there were 48 cases and 32 deaths, or 0·94 per 1,000 of strength against 73 cases and 45 deaths or 1·28 in 1882. In the Madras army the cholera deaths numbered 10 or 0·95 per 1,000 against 9 or 0·82 in 1882; and in the

Bombay army there were 9 deaths or 0·82 per 1,000 against 7 or 0·63 in 1882. Compared with the average death-rates of the ten-year period 1870–79 the cholera mortality among the Bengal troops in 1883 was 3·24 per 1,000 less; among the Madras troops it was 0·73 lower, and among the Bombay troops 0·71 less. Of the six groups of stations in Bengal the disease was confined really to two, the Gangetic Provinces and Agra and Central India groups, which recorded 39 cases with 26 deaths and 6 cases with 5 deaths respectively. Three of the remaining four groups were exempt, while there was only one case in Bengal Proper which proved fatal. The whole cholera mortality of the year took place in 15 stations, while more than a half of the total deaths were recorded in six stations belonging to the Gangetic Provinces and Oudh group.

Small-pox.

There was a greater prevalence of small-pox than usual in the Bengal army. The total cases numbered 105 against 44 in 1882 and 9 deaths against 4. The increase mainly occurred in the Bengal group of stations where 86 cases were admitted into hospital, the largest number of any year since 1870, and 7 deaths, equal to a ratio of 0·21 per 1,000 of strength. The Madras and Bombay armies recorded one death each.

Fevers.

From intermittent fevers the admission-rate for the whole army fell from 494 per 1,000 in 1882 to 359 in 1883, and the death-rate from 0·07 to 0·05, all three Presidencies sharing in the diminution. Under remittent and continued fevers there were also fewer admissions, the rate having declined from 53 per 1,000 in 1882 to 49 in 1883. Enteric fever showed an increased admission-rate in 1883 with a lower death-rate. Throughout the whole European army there were 429 admissions or 7·7 per 1,000 of strength against 357 or 6·2 in 1882, while the deaths numbered 133 or 2·40 per 1,000 against 146 or 2·55. Of the three armies enteric fever was most prevalent in that of Madras, which recorded an admission-rate of 8·6 per 1,000, more than double its ratio of 1882, and a death-rate of 2·86 against 2·09. The severity of the disease among the Madras troops was, however, much less than in the previous year, as is shown by the fact that while in 1883, 33⅓ per cent. of those attacked died, the percentage in 1882 was 52·27. Among the Bengal troops the admission-rate rose from 7·3 per 1,000 in 1882 to 8·1 in 1883, while the mortality declined from 2·90 to 2·52. In the Bombay army also the admissions rose from 5·1 per 1,000 in the previous year to 5·7 in 1883; but the death-rate fell from 1·98 to 1·55. As regards the relationship between enteric fever and age, the statistics for 1883 show that 41 per cent. of the strength of the entire army was under 25 years of age, and that among them the death-rate from this cause was 4·34 per 1,000, whilst among men between 25 and 29 years of age, forming 35 per cent. of the army, the mortality was only 1·50 per 1,000. The susceptibility of young soldiers to this fever is also clearly shown in the length of residence in India, for while the death-rate from this fever of those in their first and second years' service was 4·98 per 1,000, among those in their third to sixth years and seventh to tenth years it was 1·55 and 0·55 per 1,000 respectively. The experience of newly arrived regiments in 1883 (*see* below) also witnesses to the influence of climate in the production of enteric fever, no less than 8·95 of the total death-rate (19·96) of these regiments being due to this disease. Additional evidence of the influence of youth and short residence to this fever is afforded by the statistics of individual stations. At Lucknow, for example, out of 44 cases, 35 of which took place in one regiment composed principally of young soldiers, 33 occurred among men between 20 and 24 years of age and of less than one year's residence in India. The source of the disease, it is stated, could not be ascertained. "The sanitary condition of the barracks and surroundings was "excellent, and in the barracks occupied by the regiment which supplied most of the cases "there was no marked prevalence in any one building or locality."

Venereal diseases.

Venereal diseases were even more common in the European army in 1883 than in the previous year, the admission-rate having risen from 265 per 1,000 of average strength to 270. Of the three Presidency armies, the results of those of Bengal and Madras were the most unfavourable, each showing a slight increase, while in the Bombay army the admission-rate fell from 224 per 1,000 in 1882 to 218 in 1883. In his Report for 1883, Dr. Cunningham compares the statistics of those stations in which the lock hospital system prevailed with those of unprotected stations. In the 14 years ending 1883, the average admission-rate for the whole army in protected stations was 223 per 1,000, while in unprotected stations it was only 3 per 1,000 higher. This small difference in favour of protected stations was entirely due to the favourable results of Bombay, for both in the Bengal and Madras armies the average admission-rates for the 14 years in the protected stations exceeded those in unprotected stations. In 8 of the 14 years the protected stations recorded a smaller proportion of admissions than the unprotected stations, the greatest difference being in the

year under notice, when the rate for the former was 271 per 1,000, and that of the latter 341, or just 70 per 1,000 greater. Of the six years in which the admissions in protected stations exceeded those of unprotected stations, the greatest excess was 33·2 per 1,000 in 1872. It will thus be seen, as Dr. Cuningham observes, that "the diminution of venereal diseases in "protected stations for the army as a whole is quite insignificant."

Invaliding.

The number of men invalided during 1883 was 1,811, or in the proportion of 32·66 per 1,000 of average strength, which is less than the rate of the previous year by 0·42, and also lower than the average of the ten years 1870–79 by 10·38 per 1,000. With the exception of 1880, when the invaliding-rate was 26·31 per 1,000, that of 1883 is the lowest on record since 1870. The distribution of invaliding in the three Presidencies was not so disproportionate as in previous years. In Bombay, which contributed the largest share, the invaliding rate for 1883 was 38·08 per 1,000 against 35·85 in 1882, and 42·79 the average of the decade 1870–79. In Madras the loss from invaliding was in the proportion of 32·70 per 1,000 against 24·12 in 1882 and a decennial average of 48·71. In Bengal the invaliding rate was lowest, namely, 30·89 or 4 per 1,000 less than in 1882 and against an average 10 years' rate of 41·40. Of the total 1,811 men invalided during the year under review, 702 or 39 per cent. were for discharge from the service, and this average percentage was made up of 45 in Bengal, 40 in Madras, and 31 in Bombay. The principal diseases necessitating invaliding were anæmia and debility, phthisis pulmonalis, hepatitis, and diseases of the heart and arteries. For the army as a whole, 36·55 per cent. of those invalided were under 25 years of age as compared with 31·82 in 1882 and 33·74 in 1881. The effect of residence in India upon invaliding is shown by 18·94 per cent. of the total having been less than two years in the country, and by 57·81 per cent. having served from two to five years.

In their memorandum on Dr. Cuningham's report (see Appendix, p. 143), the Army Sanitary Commission call attention to the improvement which has taken place in the health statistics of the European army of India since 1859 when the Royal Commission began its inquiry. They say: "In estimating the possible saving of army life, the Royal Commission "considered that the death-rate of 20 per 1,000 ruling among Indian civil servants "ought to be attainable for soldiers by the application of ordinary sanitary methods. But "they went beyond data of this class, and drew pointed attention to sanitary work which "must in time be done, while they expressed a hope that when the stations and their "vicinity were brought under proper sanitary regulation 'the natural death-rate in times of "'peace of men of the soldiers' ages in India will be no more than 10 per 1,000 per "'annum.' We have already shown how the death-rates have been falling under sanitary "work in years of peace, and how they are temporarily raised in war years. But we have "now arrived at this point, that up to the time of the Royal Commission of 1859 the station "death-rates in India had been on an average 69 and 70 per 1,000, while in 1883 the rate "was 10·88 per 1,000 for the whole Indian army."

Health of newly arrived regiments.

The health statistics of newly-arrived regiments as compared with those of the army generally were less favourable than they were in 1882. The average strength was less than one-half of that of the previous year, 1,453 against 3,344, and amongst this number the admission-rate was 1,738 per 1,000, or 402 per 1,000 greater than the general rate of the army as a whole; the daily sick-rate was 82·6, or 19·7 higher; and the death-rate was 19·96, being 9·08 per 1,000 in excess of the general mortality. Compared also with the results of 1882 the health of newly-arrived regiments was far less satisfactory in 1883. From enteric fever the death-rate among newly-arrived troops was 8·95 per 1,000, over 6½ per 1,000 higher than the rate for the whole army, and 1·77 in excess of the mortality from this cause in 1882. "It is clear," the Army Sanitary Commission remark, "that large arrivals of men "new to Indian service must exercise a notable influence on the death-rates, and hence, "when there are few new regiments sent out, the general army rate will be lower than it "would be otherwise."

II.—NATIVE ARMY.

The mean strength of the Native Army of India in 1883 was 114,830, identically the same as in the previous year, and the health of these troops was on the whole very favourable. Both sickness and mortality were less than in any year since 1877 when the statistics for the whole army of India were for the first time combined. The admissions into hospital were in the ratio of 923 per 1,000 against 1,129 in 1882; the daily sick 31, or 6 per 1,000 less, and the deaths from all causes 11·76 per 1,000 against 12·24, or 14·31 including men absent from their regiments against 14·76. Sickness and mortality in 1883.

The following are the main facts regarding the sickness and mortality of the various portions of the Native Army:—

	Average Strength.	Ratio per 1,000.			
		Admissions.	Daily Sick.	Deaths.	Total Deaths, including Absentees.
Bengal Native Army	40,932	985	32	10·55	13·98
Madras ditto	27,703	782	27	12·76	17·51
Bombay ditto	23,576	994	35	12·82	14·96
Central India Regiments	5,197	595	19	7·89	10·16
Punjab Frontier Field Force	10,438	1,419	45	22·46	28·35
Hyderabad Contingent	6,983	572	20	7·59	9·31
India as a whole	114,830	923	31	11·76	14·31

In the Bengal Native Army, both sickness and mortality show a great diminution compared with the previous year, the admission-rate having declined from 1,250 in 1882 to 985 per 1,000, the daily sick-rate from 41 to 32, and the mortality from 13·34 to 10·55, or including absent deaths from 16·49 to 13·98. From nearly all diseases there was less sickness than in 1882, and where there was any increase it was very trivial. Intermittent fevers showed the most striking reduction, from 606 per 1,000 in 1882 to 396. As regards mortality the only diseases which showed a higher ratio were phthisis and small-pox, the latter being unusually prevalent during the year. The cases rose from 21 in 1882 to 50 or 1·2 per 1,000 of strength in 1883, and the number of deaths from 5 to 12. From respiratory diseases the death-rate continued to decline; during the year under notice it was 3·20 per 1,000 against 4·50 in 1882 and 6·59 in 1881. From cholera there were only 38 cases with 23 deaths, or 0·56 per 1,000 of strength against 0·72 in 1882. Enteric fever gave rise to 12 admissions, 3 of which ended fatally, as against 11 cases and 7 deaths in the previous year, apparently showing that the cases in 1883 must have been comparatively mild. Bengal Army.

The following is a statement of the health of the troops in the several geographical groups of the Bengal army:—

	Ratio per 1,000.		
	Admissions.	Daily Sick.	Deaths.
Bengal Proper and Assam	1,408	46	16·23
Gangetic Provinces	920	34	8·17
Rohilcund and Meerut	978	36	11·53
Agra and Central India	906	30	5·77
Punjab	830	45	10·80

As was the case in the two previous years, Agra and Central India on the whole recorded the most favourable results, though in 1883 the Punjab group had the lowest admission-rate. In the Bengal Proper and Assam group, as usual, sickness and mortality were higher than in any other group, but both rates were the lowest on record, the death-rate being nearly 3 per 1,000 below the average. The diminution of mortality was most marked in the Agra and Central India and Punjab groups; in the former group the death-rate was 1·41 per 1,000 less than in 1882 and 3·84 below the average, and in the latter group it was 2·50 per 1,000 less than the rate of 1882 and 3·44 lower than the average. In all groups the admission-rate was less than in 1882, and the only group which recorded a higher mortality was Rohilcund and Meerut, viz., 1·55 per 1,000, but the average rate was exceeded by only 0·34 per 1,000. Fevers, as usual, were the chief causes of admission in each of the groups,

but they were much less prevalent as compared with 1882; the most marked cases were the Agra and Central India and Punjab groups where the fever admission-rates were nearly half those of the preceding year. Bowel complaints were also less prevalent than in 1882, and below the average; respiratory diseases caused fewer admissions in all groups, but only in the Punjab group was the diminution at all marked.

As regards the chief death causes in the different groups, cholera gave rise to the highest mortality in the Lower Bengal and Assam group, where it equalled 1·80 per 1,000 against 3·01 in 1882. The next highest death-rate from this disease was 1·17 in the Gangetic Provinces and Oudh group against 0·85 in 1882. In the Agra and Central India group there were no deaths from cholera, and in the other two groups the mortality was small. The fever death-rates ranged from 2·46 per 1,000 in Lower Bengal and Assam to 0·79 in the Punjab, the latter showing a great reduction on 2·11 in 1882. Bowel complaints were also more fatal in Lower Bengal and Assam (3·28 per 1,000), whilst in the Gangetic Provinces the ratio was only 0·26. In all the groups the mortality from respiratory diseases was less than in 1882, though, except in Agra and Central India, it exceeded the average of the ten-year period 1867–76; from these diseases the death-rate varied from 4·97 per 1,000 in the Punjab to 1·59 in Agra and Central India.

In individual stations the maximum admission-rate was recorded at Edwardesabad and outposts, where it equalled 2,217 per 1,000, or 80 less than in 1882. In seven other stations the admission-rates varied between 1,500 and 2,000, while in the previous year six stations had admission-rates exceeding 2,000, and 15 stations between 1,500 and 2,000. Edwardesabad and outposts also recorded the highest mortality (39·19 per 1,000), and here respiratory diseases were the chief causes contributing no less than 59 of the total 70 deaths. In six other stations (seven in all) the mortality was above 20 per 1,000. For seven months of the year a small force of 624 Bengal troops was on service in Southern Afghanistan; the mortality during occupation was only 3·21 per 1,000 against a ratio of 36·10 during a three months occupation in 1882, and of 106·30 for the year 1881. There were only two deaths in 1883, one in hospital and one out of hospital, the former having resulted from respiratory disease. The admissions into hospital were in the ratio of 910 per 1,000.

Among the 10,438 troops comprising the Punjab Frontier force there was considerably less sickness in 1883 than in the previous year, but an increased mortality. The admission-rate fell from 1,992 in 1882 to 1,419, the daily sick-rate from 60 to 45, while the mortality was 21·46 or 5·52 per 1,000 higher, and including absent deaths, 23·35 against 18·89. Out of the total 224 deaths in this force 148, or 14·18 per 1,000 of strength, were due to respiratory diseases, the majority (104) having taken place at the two stations of Kohat and Edwardesabad with their outposts.

The health statistics of the Central India regiments during 1883 were extremely favourable. Of an average strength of 5,197 the admissions into hospital equalled 595 per 1,000 against 697 in 1882, the daily sick 19 per 1,000 against 23, and the mortality 7·89 or 2·07 per 1,000 less; but including absent deaths the rate was nearly the same, 10·16 against 10·58. The chief death-causes among these troops were fevers, chiefly remittent and continued, which occasioned 11 of the total 41 deaths, or 2·12 per 1,000, respiratory diseases following with 7 or 1·35. From cholera there were two fatal cases.

As usual the Hyderabad contingent was the most healthy body of Native troops. There was less sickness among them than in any year since 1877; but the mortality, which was 7·59 per 1,000, exceeded the ratio of 1882 by 4·47; this was due mainly to cholera, which gave rise to 15 of the total 53 deaths, or 2·15 per 1,000 against a ratio of 0·29 in 1882; respiratory diseases and anæmia and debility followed with 8 deaths each, or 1·15 per 1,000.

Madras Native Army.

The Madras Native Army was, on the whole, more healthy in 1883 than in any of the previous six years. The admission-rate per 1,000 of an average strength of 27,703 was 737, against 879 in 1882, the daily sick-rate 27, or 3 per 1,000 less, and the death-rate 10·76 against 12·01, or including absent deaths 12·51 against 14·99. Intermittent fevers stand first as causes of admission being over a third of the total, while cholera occasioned the greatest number of deaths. Out of a total of 298 deaths, 81 or 2·92 per 1,000 of average strength, were due to this disease, which, however, was little in excess of the mortality of 1882, when there were 73 deaths, or 2·64 per 1,000. Of the remaining deaths 46, or 1·66 per 1,000, were due to respiratory diseases, 21 or 0·76 to anæmia and debility, and 20 or 0·72 to dropsy. Among the Madras troops serving in Hyderabad and Nagpur the health statistics were not so favourable as in 1882; sickness was slightly more prevalent, and the death-rate rose from 11·58 to 18·50 per 1,000. On the other hand there was a great improvement in the health of the troops serving in the northern division of the Madras army, the admission-rate having fallen from 1,559 to 710, the daily sick from 44 to 27, and the death-rate from 13·97 to

7·93 per 1,000. There was also a satisfactory improvement in the health of the troops stationed in Southern India, and in Burma and the Andamans.

Bombay Native Army.

The statistics of the Bombay Native Army in 1883 were on the whole much the same as in the previous year. Out of an average strength of 23,576 the admissions in 1883 equalled 994 per 1,000 against 1,067 in 1882, the daily sick 35 per 1,000 or one less, and the death-rate 12·81 or 0·65 per 1,000 higher; including absent deaths the mortality was 14·96 per 1,000 against 13·41 in 1882.

Of the chief diseases there were only 21 cases of cholera with 11 deaths; from small-pox 104 cases were recorded against 25 in 1882, but only two proved fatal; bowel complaints were also more prevalent, while other diseases showed a decline. Respiratory diseases gave rise to the greatest number of deaths—109, or 4·62 per 1,000 out of a total of 302 from all causes; remittent and continued fevers followed with 36 deaths, and dysentery and diarrhœa with 22 deaths. Of the various portions of the Bombay army the force serving in Southern Afghanistan was the most unhealthy. Among this force of an average strength of 3,959 the admission-rate was 1,741 per 1,000, the daily sick 56, both being below the ratios of the previous year; but the death-rate rose from 35·80 to 37·64. Of the total 149 deaths, 74 or 18·69 per 1,000 of strength, were due to respiratory diseases, 15 to remittent and continued fevers, and 15 to dysentery and diarrhœa. This portion of the Bombay army was exempt from cholera. The Northern division of the Bombay army comes next in order of sickness with an admission-rate of 956, and a daily sick-rate of 33 per 1,000, both ratios being slightly in excess of those of 1882; while the death-rate fell from 7·78 in 1882 to 5·47. In the other three divisions of Aden and Sind, Konkan, and Kandeish the admission-rates were under 800 per 1,000, and the death-rates were 13·91, 9·74, and 5·33 respectively against 7·19, 11·17, and 6·26 in the previous year. Amongst individual stations the highest death-rates were recorded in Hyderabad, 19·23; Surat, 12·24; and Kaladgi, 12·05.

The Aka expedition.

During the year a small expedition, consisting entirely of Native troops, was organised against the Akas, a tribe of hill-men whose territory lies to the north of Tezpur on the Brahmaputra. This force consisted of 30 officers, 1,026 men, and 1,993 followers, and it crossed the frontier on the 17th December 1883. The disturbance was soon quelled, and the troops began to return on the 21st January 1884, and by the 1st February they were nearly all back at Tezpur. The medical history of this expedition shows that both among troops and followers serious disability and loss of service resulted from the bite of the pipsee fly, a small insect which is very numerous in the Aka country. The troops suffered more from ague and dysentery than from any other disease, while the followers suffered, in addition, considerably from respiratory diseases and diarrhœa. The mortality among the troops consisted of one case of pneumonia only; while among the followers there were in all 16 deaths, 10 of which resulted from respiratory diseases.

III.—GENERAL POPULATION.

The following statement exhibits the registered deaths from the four principal diseases and from all causes in the different provinces of India during 1883 :—

	Cholera.		Small-Pox.		Fevers.		Bowel Complaints.		Deaths from all Causes.		
	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000 of Population under registration.

Bengal.

Special measures were taken during 1883 with the view of securing greater accuracy in the registration of vital statistics in Bengal, the results for the year, however, do not show any improvement. Birth registration was carried on only in 46 towns, or one more than in the previous year, and their mean birth-rate equalled 22·08 per 1,000 of population against 22·65 in 1882. The defectiveness of the system of registration may be judged from the fact that the town birth-rates varied from 6·40 in Darjeeling to 49·17 in Jamalpore.

The year 1883 in Bengal was a comparatively healthy one, though unfavourable from an agricultural point of view, the rainfall having been deficient and irregular, and 8·11 inches below the average, causing a failure of the crops and much privation among the poorer classes. Still the registered deaths were fewer by 103,975, the total numbering 1,245,676 or 18·82 per 1,000 against 1,349,651 or 20·41 in 1882. The imperfectness of registration is further shown in the great differences of the district death-rates which ranged from 9·93 per 1,000 in Monghyr to 36·07 in Nuddea. Amongst the rural population the mortality was 18·49 per 1,000, while that of the towns was 27·28, the last being a mean of ratios varying from 9·56 in Sudharam to 46·97 in Gya.

Of the chief diseases contributing to the year's mortality, cholera was considerably less prevalent than in 1883, the deaths having fallen from 182,352, or 2·75 per 1,000 in 1882, to 90,439 or 1·36. All the districts were affected, but the entire mortality was returned from less than 7 per cent. of the total 248,751 villages. The disease prevailed most severely in Nuddea and Julpigoree districts, which recorded death-rates of 4·69 and 4·17 per 1,000 respectively; in four other districts the ratios ranged from 3·73 to 3·00, and in five from 2·40 to 1·95; but while 11 districts suffered conspicuously from cholera in the year under notice, 28 of the total 45 districts recorded death-rates ranging from 1·96 to 6·20 in 1882. The disease was most severe in the dry and hot months of April, May, and June, and, as usual, subsided during the rains. With very few exceptions the fairs held in the province during the year were exempt from cholera, although in several of them, it is reported, no sanitary precautions were adopted to prevent its incidence. "The practical result of the "cholera experience in Bengal during 1883," the Army Sanitary Commission state, "confirms that of all previous years. We know nothing of the real disease cause. This "varies in intensity, so far as can be estimated by the death-rates in different years and in "different localities, and the conditions which appear to affect the local mortality most "markedly are those which may all be classed under the head of defective sanitation, such as "filth, bad water, crowding of dwellings and villages, permanently and temporarily, by influx "of pilgrims or other passengers, and these causes of augmented local mortality point to the "required remedies."

The mortality from small-pox in 1883 was lower than that of any year in the preceding decade, excepting 1875 and 1877. There were 9,714 deaths, or 0·14 per 1,000 of population, against 13,651 or 0·20 in the previous year. Bogra was the only district in Bengal which enjoyed complete immunity from the disease. The incidence of the disease was marked during the year with more or less severity in 80 circles of registration against 33 in 1882, and it was absent from 284 against 280, and affected 1·73 per cent. of the villages against 2·33 per cent. in the previous year. Of the total deaths 1,383 took place among children under one year of age, and more than a half, or 5,018, among children between one and 12 years.

Fevers prevailed with diminished severity during 1883 as compared with the previous year. The deaths numbered 913,766, or 13·81 per 1,000 of population, against 929,943 or 14·06 in 1882, showing a decrease in the year under notice of 16,177. Of the 45 districts, 19 returned enhanced mortality against 22 in the previous year; and fatal cases were returned from 57 per cent. of the villages against 54 per cent. in 1882. Fever mortality varied greatly in the different districts; the highest death-rates were 30·12 in Rajshahye and 27·60 in Nuddea. In the previous year Nuddea and Burdwan were the chief sufferers, but it is satisfactory to learn that in both these districts fevers were diminishing. The Army Sanitary Commission instance a number of cases showing the local fever causes in 1883. The main causes of fever mortality, they say, are purely local, and are connected with the drainage defects and marshy condition of defined areas which surround towns and villages. The Commission urge that "it should be kept in view, as an axiom of sanitary work in "India, that disease causes are chiefly to be found in the dwelling itself and its immediate "surroundings."

Deaths from bowel complaints, which the Sanitary Commissioner considers to be enormously under-registered, amounted to 55,270 or 0·83 per 1,000 against 61,382 or 0·92 in 1882, showing a decrease of 6,112. The year's mortality is reported to have occurred in 9 per cent. of the villages as compared with 10 per cent. in 1882.

In the city of Calcutta there was an improvement in the public health as compared with the previous year, though cholera again prevailed very extensively. From all causes 12,325 deaths were registered, equal to 28·44 per 1,000 of population, against 13,177 or 30·4 in 1882. From cholera 2,037 deaths were reported or 4·70 per 1,000, being within a fraction of the abnormal mortality of the previous year. Fevers continued to show a steady decrease; the deaths fell from 3,818 or 8·80 per 1,000, to 3,443 or 7·94; there was also a marked decrease in the mortality from bowel complaints; but small-pox deaths rose from 17 to 73.

Madras.

Although in the Madras Presidency the year 1883 was one of fair average rainfall and the prices of food grains remained low, it was not, on the whole, a healthy year. The vital statistics for the Presidency show that 791,774 births were registered during the year, equal to 27·7 per 1,000 of population, the highest ratio which has yet been reached, against 751,104 or 26·0 in 1882. The district birth-rates varied from 13·7 in the Nilgiris to 40·9 in Madras. In 12 out of 22 districts the average rate was exceeded, and in only one district (Malabar) the birth-rate was less than the mortality. With the increase in the births there was also a considerable rise in the deaths, which numbered 541,993, or 19·0 per 1,000, against 470,700 or 16·2 in 1882, showing an increase of 71,230. But this excess in the death-rate is more apparent than real, and is due in a great measure to the fact that for the first time the census figures of 1881 were utilised in computing the statistics, which differed from those on which the statistics for 1882 had been based by more than a third of a million less.

Under every head of disease there was an increase in mortality. Cholera was considerably more prevalent than in any year since the famine year 1877. The deaths numbered 36,284 or 1·27 per 1,000 of population against 23,604 or 0·81 in 1882. The three districts of Vizagapatam, Kurnool, and South Canara were exempt from the disease, and in the districts of Godavari, Kistna, and Nilgiris it prevailed but slightly. Cholera was most severe in South Arcot, Trichinopoly, Tanjore, Tinnevelly, and Madura, which together yielded slightly over two-thirds of the total mortality. The disease was much more severe in the towns than among the rural population, the death-rate of the former being 3·8 per 1,000, and that of the latter 1·1. In some of the towns the mortality was excessive, especially in Gudiyatam (North Arcot) where it reached 34·2 per 1,000 of its population, and in Karur (Coimbatore), where it was 25·2. In discussing the statistical data for this disease, the Army Sanitary Commission notice that the deaths during the nine years ending 1883 were more than double the number in the previous nine years, and even omitting the enormous death-rate of the famine year, 1877, the mortality in the latter period was greater. "It follows as a matter of "course," they say, "that no sanitary work which has been done in the towns and villages

" of Madras Presidency has materially influenced local conditions during the whole 18 years, " taken at least over the entire population. There are exceptional cases which add stronger " proof to the rule that cholera is a test of the health condition of localities in Madras " Presidency, as it is everywhere, for we only know cholera through its manifestations in " localities, and we have as complete proof as can be obtained of what the sanitary condition " of affected towns and villages really is, and this knowledge leads us directly to the practical " remedies required."

Small-pox also was very prevalent, causing more deaths than in any year since 1878, viz., 37,975 or 1·33 per 1,000 against 20,159 or 0·69 in 1882. Every district was affected, those of Madras and Malabar the most severely, which recorded death-rates of 4·9 and 4·3 per 1,000 respectively. Strenuous efforts were made on the part of the Madras municipal authorities to counteract the heavy mortality by the extension of vaccination; "but the poor " people are," the Sanitary Commissioner states, " so firmly wedded to the belief that the " disease is a visitation of the goddess Mariamma, and to be looked upon rather as a beneficent " mark of her favour than any misfortune, that all merely persuasive efforts on the part of " Europeans seem useless to combat the epidemic." Of the total deaths 61·3 per cent. occurred among children under 12 years of age. The registered deaths from small-pox for a period of 13 years show that the disease is by no means an occasional visitant in the Madras Presidency. "In the present state of public opinion on the subject of vaccination," the Army Sanitary Commission observe, "it is not likely that these figures with their recurring " years of aggravations will be materially reduced by the vaccination service; although one " obvious result of the data as a whole is to point clearly to the necessity of concentrating " effort on the vaccination of infants. But when taken in connection with the cholera " mortality they strengthen the conclusion that both epidemics are at present very unneces- " sarily aggravated by the neglect of sanitary measures."

Fever deaths were more numerous than in 1882 by 15,225, the total number being 203,786 or 7·04 per 1,000 against 188,561 or 6·54. District death-rates varied from 1·7 per 1,000 in Tanjore to 14·0 in Kurnool, the next highest were 11·8 in Malabar, 10·9 in Vizagapatam, and 10·0 in Cuddapah. Statistics show, as the Sanitary Commissioner observes, "that it is during the cold and monsoon months that the greatest number of " victims succumb to fevers, that it is more a climatic than a mysterious malarial malady. " When the poor people learn how to protect themselves by proper clothing and food from " rapid changes of temperature, then the muster-roll of deaths from fever will diminish." But the Army Sanitary Commission urge that the prevalence of disease must first be reduced by the sanitary improvement of dwellings and their surroundings. "On this," they say, " there will follow improved stamina and greater ability to work, besides improved habits of " life, and, as a matter of course, there will be better food and better clothing, and these in " their turn will further improve general health."

Deaths from bowel complaints amounted to 22,098 or 0·7 per 1,000, exceeding the number of the previous year by 2,140. The highest district death-rate was 5·6 per 1,000 in Madras, followed by 2·4 in South Canara; in four other districts the mortality was over 1 per 1,000.

The health of Madras city in 1883 was not so good as in the previous year, the deaths having risen from 14,169 or 35·6 per 1,000 to 15,882 or 39·8. This increase was entirely due to the unusual severity of small-pox, from which there were 1,957 fatal cases, being 1,602 over the number of 1882; bowel complaints also were more prevalent, but cholera deaths declined from 461 to 169, and fever deaths from 3,706 to 3,470.

Bombay.

In the Bombay Presidency the year 1883 was an unhealthy one; the rainfall was unusually heavy in some districts, and at one season of the year fears were entertained of scarcity over extensive areas of the Deccan and the Konkan, owing to a pestilence of locusts. The energetic measures, however, which were taken by order of the Government for their destruction in the affected districts were attended with success, whilst the strong easterly wind which set in after the rains, blew great numbers of them into the sea.

The number of births registered during the year was 501,891 or 30·50 per 1,000 of population against 491,346 or 29·86 in 1882. In each of the five divisions of the Presidency, except the Konkan, more births were registered than in the previous year. Registration still continues very backward in the Konkan and in Sind, especially the latter, which recorded a birth-rate of only 18·62 per 1,000; but on the whole the district ratios show that the average was fairly maintained over the Presidency. The registered deaths exceeded the number of the previous year by 76,780, the total being 420,198 or 25·53 per 1,000 against 343,418 or 20·87 in 1882. The year's death-rate was made up of extremes, varying from 9·19 per 1,000 in Upper Sind frontier to 41·97 in Kandesh. The increase was pretty general, for 17 districts out of a total of 24 recorded higher death-rates than in 1882. Amongst children under five years of age the mortality was again very high, being in the proportion of 40·54 per cent. of the total deaths.

From all the chief diseases the mortality was much heavier than in the previous year. The Army Sanitary Commission notice that the excess of epidemic deaths in 1883 over the average of the 10 previous years was 36,567. "The practical conclusion therefore is," they say, "that there was a great augmentation in epidemic susceptibility among the people in 1883, "a sure proof that sanitary work has not yet reached its causes, and pointing at the same "time clearly to the sanitary measures required, and the urgent necessity of taking them in "hand without delay."

Cholera prevailed with very great severity, causing 37,954 deaths or 2·31 per 1,000 of population against 7,904 or 0·48 in 1882, showing that the mortality of 1883 was nearly five times greater than that of the previous year. The severity of the epidemic was, however, confined chiefly to the North Deccan division, the five districts of which yielded 30,298 of the total cholera deaths, and a death-rate of 7·12 per 1,000, over three times greater than the mortality for the whole Presidency. In the Sind division, also comprising five districts, the disease was entirely absent. Although the mortality from cholera was so unusually large, the number of villages affected by it was only 3,199 or 13 per cent. of the total 24,536; but in the North Deccan division the percentage was 33. At the request of the Local Government the Sanitary Commissioner drew up simple instructions for the guidance of villagers regarding measures to be taken in case of an outbreak of cholera, which, if properly carried out, it is hoped will be the means of saving many lives.

Small-pox also prevailed in an epidemic form more or less throughout the Presidency. The deaths numbered 13,404 or 0·81 per 1,000 against 1,630 or 0·10 in 1882. The only district that was free from the disease was Upper Sind Frontier, while in the others the mortality ranged from 0·06 in Thar and Parkar to 2·18 in Surat. Of the total mortality 33·9 per cent. took place among infants under one year, and 51·9 per cent. among children between 1 and 12 years of age, the remaining 14·2 per cent. being among persons exceeding that age. Statistics show that there is a large number of young children unprotected by vaccination against small-pox, especially in the towns. "I think a general feeling is gaining "ground," the Sanitary Commissioner states, "that the time is fast approaching when it will be "desirable to make vaccination compulsory throughout the Presidency. If it were so, there "is no doubt that the death-rate would in epidemic seasons be considerably lower than it "has hitherto been."

Under fevers, 266,741 deaths were registered, equal to 16·21 per 1,000 of population, exceeding the number of the previous year by 23,287 or 1·41 per 1,000. Of the five divisions the highest ratio (20·70) was recorded in the North Deccan, and the lowest (11·42) in Sind. By districts the highest proportion of fever deaths to population was 24·71 in Kandeish, and the lowest, 7·47, in Bombay City. In the Sind Division the deaths ascribed to fevers formed no less than 86 per cent. of the total deaths from all causes in 1883, against 89 per cent. in the previous year, and 86 per cent. in 1881. "The chief cause," the Acting Deputy Sanitary Commissioner states, "may no doubt be found in flooding of the "country by the River Indus. The inundation of 1882 stands unrivalled. Vast tracts of "land were covered four months with the water which overflowed from the canals. These "districts became very unhealthy, and severe fevers, resulting in a largely increased death-"rate followed. The Shikarpur district was, perhaps, the most severely affected, and "although the death-rate does not compare favourably with that of 1881 (although the "country was free from flooding in 1883), I believe the increase in the number of deaths in "1883 over 1881 must be in a great measure attributed to latent disease induced by the "malarious influences of 1882."

Bowel complaints are reported to have caused the death of 35,292 persons or 2·14 per 1,000 against 28,353 or 1·72 in 1882. As with the other death causes, the North Deccan recorded the highest divisional death-rate, viz., 3·36 per 1,000. The general diffusion of the mortality is shown by the fact that 16 districts out of 24 recorded a higher death-rate than in the previous year. Kandeish, in the North Deccan division, headed the district death-rates with 5·14 per 1,000.

In Bombay City the public health during 1883 was most unsatisfactory, and the number of deaths rose from 20,468 or 25·89 per 1,000 in 1882 to 23,530 or 29·12. Cholera prevailed very extensively, and occasioned 1,027 deaths against 192 in the previous year; the mortality from small-pox also showed a considerable increase, the deaths numbering 1,461 as compared with 92 in 1882. Owing to the alarming increase in the deaths from these two diseases steps have been taken for the provision of hospitals for the special treatment of patients suffering from them. From fevers and bowel complaints there was a very sensible increase, the former causing 5,903 deaths or 450 more than the number recorded in 1882; and the latter 1,806, being 188 in excess of the previous year.

Progress continued to be made in the registration of vital statistics in the Punjab. During 1883 there were 734,912 births registered, equal to 39·90 per 1,000 of population, again

690,524 or 36·65 in 1882. Out of a total of 32 districts, 16 returned birth-rates exceeding 40 per 1,000; in 8 the ratios were over 30 per 1,000; and in the remaining 8 they ranged between 29·68 and 10·04 per 1,000. The general birth-rate was greater than the death-rate by 14 per 1,900, "a result," the Sanitary Commissioner observes, "which speaks very "favourably for the steady improvement of birth registration."

The rainfall of the year was below the average and irregular in distribution, still the harvest was good; the staple articles of food were plentiful, and the public health was, on the whole, favourable. Deaths were registered to the number of 475,741 or 25·25 per 1,000 against 504,799 or 26·79 in 1882.* In 15 districts the mortality was below the provincial rate, ranging from 24 to 16 per 1,000; in the remaining 17 districts the death-rates varied between 25 and 35 per 1,000.

The unusually healthy character of the year is evidenced by the low death-rate from nearly all causes, but more especially from fever and bowel complaints. Cholera in an epidemic form was present only in the Delhi division, where two small outbreaks occurred, which were, however, confined to 25 villages, 5 being situated in the Delhi and 20 in the Gurgaon district. The total number of cholera deaths was 190 against 59 in 1882, and of these the above two districts yielded 180. Out of 54,973 villages the entire mortality was returned from 52.

Small-pox was considerably more prevalent than in the previous year, the fatal cases having increased from 6,379 or 0·34 per 1,000 to 12,105 or 0·64; but its severity was felt only in 11 districts, notably in Karnal, Peshawar, Rohtak, and Gurgaon, which together returned more than half (6,878) of the total mortality. It would appear, however, that a great number of deaths registered under this head were really due to measles. "It has been "reported to me," the Sanitary Commissioner states, "that chaukidars (village watchmen) and "others find it difficult to diagnose one from the other, and in many instances return deaths "from measles as deaths from small-pox." Children as usual were the chief sufferers, as is shown by the fact that 96 per cent. of the deaths occurred among children under 12 years of age. Since the reorganisation of the Vaccination Department in 1881, satisfactory progress has been made in vaccination work, "and there was every prospect," the Army Sanitary Commission notice, "of a lower death-rate from small-pox, until the rise in 1883 to nearly "double the rate of 1881 and 1882 threw doubts on the future. There are many things "about small-pox which have yet to be learned, and, amongst others, this very matter shown "in the Punjab experience, which, however, is not peculiar to India, namely, how it happens "that, with an improved and extended vaccination service, the death-rate should suddenly "duplicate itself. We have no present means of knowing, but in this as in other sanitary "questions, we must in the meantime be guided by experience. We must go on improving "the general sanitary condition of the population, to render the people less liable to epidemics, "and the efforts of the vaccination staff must be exclusively directed to the protection of "infants, for until the births are overtaken by the vaccinations, we shall have no right to "complain of occasional epidemics of this disease."

The number of deaths registered under fevers was 306,185 or 16·25 per 1,000 of population, being 40,495 or 2·15 below the mortality of the previous year, and 5·69 per 1,000 less than the quinquennial mean. These years, however, contain the famine period 1878–79; still, compared with the three subsequent years 1880–82, the rate for 1883, as pointed out by the Army Sanitary Commission, shows a reduction of over 2 per 1,000, "which," they say, "would be so far satisfactory if it really were due to the advance of sanitary improve-"ment. This, however, is doubtful, for the Sanitary Commissioner appears to have shown "that, just as the great fever rates of 1878 and 1879 were due to the accidental intercalation "of food scarcity, which increased the susceptibility of the people to the action of ordinary "fever causes, so the lower death-rate of 1883 was mainly due to the reduction of rain in "that year." In seven districts the fever death-rate was over 20 per 1,000, Muzaffargarh recording the highest, viz., 29·27; in the remaining 25 districts the ratios ranged from 17·91 in Shahpur to 5·91 in Simla.

From bowel complaints the deaths amounted to 14,607 or 0·77 per 1,000, being 1,353 less than the number recorded in 1882. Amongst other diseases, chest affections appear to be very prevalent and fatal in the Punjab during the winter and early spring months. From these diseases, 30,681 deaths were registered. The Army Sanitary Commission consider "that the Sanitary Commissioner is doing good service to the public health cause in the "Punjab by rescuing these deaths from the general confusion during recent years; for, in so "doing, he has shown that climate has a very important influence at present, without "adequate compensation in local habits on the public health of the province, and that the "mortality entered under this new head is of far more importance numerically than the "mortality from cholera."

The year 1883 in the North-Western Provinces and Oudh was on the whole a healthy one. The rainfall was light, especially in the autumn months, but it was well distributed, and

food grains were plentiful and unusually cheap. Registration of births and deaths continued to improve. The number of births registered during the year was 1,801,401 or 40·84 per 1,000 of population, the highest ratio on record since 1879, when the system of birth registration was completed, and against 1,656,159 or 37·54 in 1882. It is worthy of remark also that the birth-rate of 1883 was the highest in any of the provinces of India. The total registered deaths numbered 1,216,297 or 27·57 per 1,000, less than in any year since 1877, and 268,820, or 6·10 below the mortality of 1882. It will be seen that the birth-rate exceeded the death-rate by 13·27 per 1,000.

Cholera was less prevalent here during 1883 than in any of the previous nine years, and the only district in which it occurred in anything like epidemic form was Banda, while even there the disease was confined to special localities. The total deaths numbered 18,160 or 0·41 per 1,000 against 89,372 or 2·02 in 1882. Out of 49 districts 3 were entirely free of cholera, and only 7 were affected with any severity. The district of Banda recorded 3,845 deaths or 5·50 per 1,000 of its population. Mirzapur followed with 1,689 or 1·48, Ghazipur with 1,419 or 1·39, and Benares with 1,233 or 1·38 per 1,000. The urban mortality was more than twice as great as the rural mortality, namely, 0·81 against 0·39. Only 2·4 per cent. of the total 105,421 villages recorded cholera deaths.

Deaths from small-pox were much more numerous than in 1882, or in any year since 1869, with the exception of 1878. From this disease 136,641 deaths were recorded in 1883, or a ratio of 3·14 per 1,000, against 26,628, or 0·60, in the previous year. The districts most affected were the central and northern districts of Oudh and the adjoining tracts of Rohilcund north of the Ganges. The mortality in the districts of Bara Banki, Hardoi, and Lucknow, situated in the very centre of Oudh, was especially high, viz., 17·53, 14·15, and 13·80 respectively, the mean of the three being 15·16 per 1,000 of population. "The "nearest approach to a record like that," the Sanitary Commissioner states, "occurred in "the three districts of Oudh (Sitapur, Hardoi, and Unao) in 1878, when their mean was "11·10. And I think there can be no doubt that, as a matter of recent history, Oudh is "the country of this province in which small-pox has greatest power. And, at the same "time, it is the portion of the province in which vaccination has made least progress."

Owing to the favourable climatic conditions of the year, fevers caused a smaller mortality than in 1882, the number of deaths being 830,258 or 18·82 per 1,000 against 1,098,414 or 24·90, showing a decrease in 1883 of 268,156 or 6·08 per 1,000. Tarai, as usual, headed the districts with a ratio of 41·61 or more than double the provincial rate. Five other districts recorded ratios varying from 25·11 to 27·41. "It is to be remembered always," the Sanitary Commissioner observes, "that these ratios of mortality from fever disease are "exaggerated proofs of its prevalence, because a larger proportion of the deaths recorded "under the head fever have really happened from quite other causes; and I think it likely "that if these deaths from other causes could have been eliminated from the record in 1883, "which was certainly a year of extraordinary absence of fever disease, the ratio for fever "would have been very light."

The mortality from bowel complaints was considerably below the average of former years, the total deaths numbering 66,530 or 1·50 per 1,000 against 93,661 or 2·12 in 1882. By districts the highest death-rate was recorded in Hamirpur, viz., 11·41, Garhwal following with 11·06; in six other districts the ratios ranged from 8·47 to 5·46, and in 11 others the provincial ratio was exceeded. The Sanitary Commissioner is of opinion that most of the deaths recorded under bowel complaints may be attributed to dysentery.

Central Provinces.

In the Central Provinces the year 1883 was an unhealthy one, though food was generally cheap and abundant. The area of registration of vital statistics was slightly increased, and the population raised from 8,802,040 to 8,817,185. Amongst this population, 357,864 births were registered, or at the rate of 40·59 per 1,000, being 9,464 less than the number of the previous year. Out of the 20 districts the birth-rate was above the provincial average in 8 (Murwara being conspicuous with a ratio of 54·29), and below in 12. The registered deaths rose from 263,368 or 29·98 per 1,000 in 1882 to 304,763 or 34·56, showing an increase in 1883 of 40,895 or 4·58 per 1,000. This increase was spread over 13 districts, and was contributed to by all the chief diseases.

Cholera was much more prevalent in 1883 than in the three previous years, and caused the death of 16,235 persons or 1·84 per 1,000 of population against 11,932 or 1·36 in 1882. The epidemic began in May and reached its height in August, when nearly a half (7,944) of the mortality was recorded, it then began to decline, until in December no cholera death was reported. As regards the mortality in individual districts, statistics show that those which suffered most in 1882 had comparatively little cholera in 1883, while those which had few deaths in 1882 were the principal sufferers in 1883. In the four districts of Burhanpur, Chindwara, Wardha, and Nagpur, the disease appears to have been very severe, the death-

rates ranging from 9·72 to 6·96 per 1,000. Notwithstanding the severity of the epidemic all the deaths were furnished by less than 5 per cent. of the 28,427 villages. In some of the towns the mortality was excessive, especially in Narkher in Nagpur district, where, out of a population of 7,061, the deaths numbered 300 or 42·49 per 1,000. The two great fairs of the provinces, Birman and Ramtek, escaped the epidemic. "The epidemic history of 1883 "confirms," the Army Sanitary Commission state, "that of all previous epidemics. It has "shown that before there can be wide-spread epidemic mortality, there must be cholera, "more or less, existing over a country, wherever it may come from. That, when cholera is "present, all the population groups do not necessarily suffer. Some, or rather the large "majority, escape in any given year, otherwise the country would be depopulated, but the "escape of one year is no guarantee for another year's immunity. That local cholera "outbreaks are intimately related to filth, damp, crowding, and bad water, but that, by "preventing these insanitary conditions at fairs, the people are protected from cholera "which at the very time may be causing the loss of life in their homes."

Small-pox was also more fatal in 1883 than in the previous year. All the districts were affected; but the entire mortality (4,696 or 0·53 per 1,000) was recorded in only 7 per cent. of the total villages. In 1882 the deaths from this disease numbered 3,945 or 0·45 per 1,000. The provincial ratio was exceeded in 9 districts out of 20, 4 recording ratios considerably higher than any of the others, viz., Nimar, 3·60; Burhanpur, 2·06; Mandla, 1·65; and Damoh, 1·41. In no other district did the mortality exceed 1 per 1,000 of its population. Of the total deaths, 1,732 occurred among children under one year of age, and 2,406 among children between one and twelve years.

The deaths ascribed to fevers numbered 175,119 or 19·86 per 1,000 against 152,407 or 17·31 in 1882. But there appears to be little doubt that a large number of deaths returned under fevers really resulted from other causes. The question was specially inquired into by the Civil Surgeons of the Hoshangabad and Chanda districts, with the result that out of 77 deaths said to be due to fever investigated in the former district only 41 per cent. were apparently caused by fever; and of 150 cases in the latter district only 27 per cent. were actual fever deaths. A further inquiry was also made by the Civil Surgeon of Hoshangabad with the view of ascertaining the true proportion due to each of the most easily recognised diseases. Out of 365 deaths investigated he found that 35 per cent. against 69½ returned by the Police were due to fever, 20·8 to bowel complaints, 16·7 to chest diseases, and 27·4 to other diseases. The Army Sanitary Commission point out that if these ratios could be accepted as general, the fever mortality for the Central Provinces, instead of being 57 per cent. of the total deaths would be 35 per cent., and that the fever death-rate would be reduced from 19·86 per 1,000 of population to 12½, "which is a third more than has been assigned under "the present registration to other provinces of India. . . . It follows," the Commission state, "that, making every deduction for errors in diagnosis, the abatement of fever causes "constitutes the sanitary problem of the Central Provinces."

Under bowel complaints 26,623 deaths were registered equal to 3·02 per 1,000 of population, being 1,984 in excess of the number of the previous year. The district of Sambalpur, as usual, was conspicuous by the high death-rate (12 per 1,000) due to these diseases. "It would appear," the Army Sanitary Commission remark, "as if these bowel "complaints at Sambalpur were of local origin, because, notwithstanding the supposed "relation of cholera to these affections, Sambalpur had not a single death from cholera in "1883, and its previous five years' cholera rate had been only 1·42 per thousand. Bad "unwholesome drinking water may be one cause of prevalence of bowel diseases in this "district, as the people appear to be infested with worms."

In Berar the year 1883 was one of excessive mortality. Not only was there a severe epidemic of cholera, but all the other forms of disease appear to have been unprecedently active, especially fevers and small-pox. This special unhealthiness is attributed to an abnormally high temperature during the months of April and May and an unusually heavy rainfall, which for the year amounted to 53 inches against an average for the previous 14 years of only 33 inches. The registration of vital statistics is reported to have been fairly carried out during the year, though there is yet much room for improvement. The number of births registered was 105,921 or 40·3 per 1,000 of population less than in 1882 by 4,533 or 1·7 per 1,000; and the registered deaths amounted to 135,081 or 51·3 per 1,000, a greater number than in the previous year by 57,867 or 21·9 per 1,000. It will thus be seen that the death-rate for 1883 exceeded the birth-rate by 11 per 1,000. The most unhealthy months of the year were July, August, and September, when nearly one-half of the total deaths occurred. As usual during epidemics the mortality amongst children was excessive, no less than 51¼ per cent. of the total registered deaths having taken place among children under five years of age. "The insanitary condition in which the people live," the Sanitary Commissioner remarks, "is sufficiently prejudicial to the rearing of children to, in

"itself, account, in a great measure, for the high rate of mortality among the infant "population, and the experience of the past year further shows that during epidemics this "insanitary condition makes itself felt in a much greater degree, and that whenever epidemic "disease occurs, children suffer the most."

Cholera accounted for 27,897 deaths or 10·60 per 1,000 of population against 3,573 or 1·34 in 1882. The epidemic commenced about the middle of April at two points remotely distant from each other, one in the extreme south in the Basim district, the other in the north in the suburbs of Amraoti, and it was confined to these two districts until June, when the epidemic became general throughout the province. The chief distribution of the disease, however, was in Ellichpur and Basim districts, where the death-rates reached 19 and 13·3 per 1,000 respectively. Out of a total of 5,564 villages 33 per cent were affected by cholera; being nearly four times greater than the number in the previous year. The Sanitary Commissioner was of opinion that the severity of the epidemic had some connection with the heavy rainfall of the year; "but taking the evidence furnished by the data as a whole, we "should scarcely be justified," the Army Sanitary Commission state, "in adopting the "conclusion." There can be little doubt, however, that the general insanitary condition of the villages aided considerably in developing the epidemic.

Small-pox prevailed in an epidemic form throughout the year, visiting all the districts, though the entire mortality was furnished by less than 1·1 per cent. of the villages. The deaths numbered 3,858 or 1·46 per 1,000 of population, more than ten times greater than the mortality of 1882. By comparing the death-rates for the 16 years ending 1883 it is seen that of late years there has been a considerable diminution of small-pox. For the first eight years of this period the aggregate death-rate is 14·8 per 1,000, and in the second eight years it is only 7·53. This decrease of mortality co-existed with a considerable increase of vaccination, as is shown by the fact, that while in the first eight-year period the aggregate ratio of successful vaccinations per 1,000 of population was 104·1, in the second period the aggregate ratio was 255·4 per 1,000.

The deaths ascribed to fevers numbered 53,593 or 20·37 per 1,000 against 39,340 or 14·95 in 1882. This mortality was generally distributed, all the registration circles having returned deaths, and 72 per cent. of the 5,564 villages. "Attention has been repeatedly drawn in "previous reports," the Sanitary Commissioner observes, "to the constant relation existing "between rainfall and fever mortality. With the advent of the rains the temperature falls, "soil and air become saturated with moisture, the days are hot and the nights chilly, owing to "rapid evaporation causing sudden alternations in temperature, and the people, as a rule, are "underclad. The consequence of this exposure to cold, chills, and damp is an increase of "sickness and mortality generally by lowering the disease-resisting powers of the people, and it "is at this season of the year that fevers both intermittent and remittent are rife. The best "protection against these climatic fever causes is better drainage and warmer clothing, "sufficient to protect the body from receiving a chill." While fully admitting the influence of wet years on the prevalence of fever, the Army Sanitary Commission urge that the treatment of local causes by sanitary measures should not be neglected. "We have little "doubt," they say, "that if the towns and villages were placed in a thoroughly wholesome "condition there would be a great reduction in the district fever death-rates; but looking "at the relation between these rates and the district rainfall, it seems not at all unlikely that "the local topography exerts a not unimportant influence on the amount of fever."

The deaths registered under bowel complaints amounted to 19,044 or 7·24 per 1,000 against 13,546 or 5·1 in 1882. By districts the ratios varied from 0·8 per 1,000 in Wun to 11·3 in Akola. "It seems likely," the Army Sanitary Commission remark, "that the higher "death-rate of 1883 may have had some relation to the severe cholera epidemic of the same "year, as there was a correspondence between the monthly deaths from both diseases."

Assam.

Of late years registration of vital statistics in Assam has made great progress, and with the exception of some hill tracts the entire province in 1883 was brought under the system. Out of a total population, according to the census of 1881, of 4,881,426, births and deaths were registered among 4,527,934; but the results do not manifest the same improvement in accurate registration as in the previous year. The registered births fell from 112,444 or 24·83 per 1,000 in 1882 to 108,269 or 23·91 in 1883, and the deaths rose from 117,384 or 25·92 to 122,932 or 27·14, thus showing an excess of deaths over births of 14,663 or more than 13 per cent. "Both rates" (birth and death), the Army Sanitary Commission remark, are evidently under the truth, but both rates show good registration when all the circumstances are taken into account, and we must hope that as the work has been fairly started, the results in future years may teach us more of the real sanitary condition of the province."

There was a marked diminution in cholera mortality as compared with 1882; but it was still much in excess of either of the two previous years. In 1883 the deaths numbered 14,908 or 3·29 per 1,000 against 21,055 or 4·66 in 1882. Every district suffered, but the entire mortality was confined to 15½ per cent. of the total 13,296 villages. Four out of the eight districts of the province showed an increased mortality, notably Darrang, which recorded a cholera death-rate of 9·28 against 3·37 in 1882. With reference to the monthly incidence of the disease the Sanitary Commissioner states: "The figures are again confirmatory of the "curious fact which has so frequently attracted observation, and especially in the comments "of the Army Sanitary Commission on the Assam Sanitary Report for 1881, that the "cholera invasion of Assam presents a striking seasonal difference in each of the two great "valleys (Brahmaputra and Surma) into which the province is divided. The figures are not "so striking in their contrast as for 1882; but the fact stands out clearly that cholera in "Assam fades away in a remarkable manner when the water overspreads the land, leaving "the Surma valley more like an archipelago than a provincial area."

The deaths registered under small-pox amounted to 6,162 or 1·37 per 1,000, nearly double the totals in the two previous years. Of the year's mortality, 1,325 deaths took place among children under one year of age, and 3,179 among those under 10 years of age. All the districts showed an increased mortality except Nowgong and Sibsagar, the excess being most marked in Cachar, where the deaths rose from 23 in 1882 to 1,623 in 1883, and in Sylhet from 378 to 2,584.

Fevers accounted for 67,494 deaths or 14·90 per 1,000 against 60,218 or 13·43 in 1882. In the three districts of Darrang, Nowgong, and Sibsagar there was a slight decrease in fever mortality, while the remaining five districts showed an increase; but only in Goalpara and Sylhet was the increase at all considerable. In Goalpara the mortality rose from 26·27 to 32·28, which is more than twice as high as the provincial rate. The increase was mostly due to the spread of the disease known locally as kalar azar, a paludal fever which appears to be prevalent among the Garos resident in low lands of the Goalpara subdivision. Steps were taken to relieve the villages affected with this disease; "but it is difficult," the Sanitary Commissioner says, "to relieve the sufferers. They believe in incantations, and will not take "European medicines; they cannot be persuaded to undergo hospital treatment as in-patients, "and they live surrounded by every conceivable insanitary condition in a country which for "the greater part of the year is practically inaccessible. To add to the difficulty, the fever is "generally of a lingering character, the sick dying ultimately from blood degeneration, and "in their impatience the Garos will not accept prolonged treatment, which is essential to "their cure." As regards the nature of the disease, the Commissioner states, "that it is a "marsh ague in its causation, intensified through chronic lapses into a blood taint, which "passes into anæmia and organic congestions, and that it is only especially fatal because the "sick among Garos are left uncared for, unnourished, and exposed to continued relapses." In discussing this fever, the Army Sanitary Commission remark: "No doubt lives might be "saved which are at present lost for want of medical treatment; but the account of this "*kala-azar*, or black sickness, shows that it is a very fatal form of Terai fever, prevalent in "districts situated at the junction of hills with the low Assam plain, occasionally extending "up the lower hill ranges, and causing death by visceral complications of a very intense "character."

The registered mortality from bowel complaints in 1883 was almost identical with that of the previous year, the deaths numbering 14,474 or 3·19 per 1,000 against 14,374 or 3·13 in 1882. These complaints showed a decrease in the district of Darrang, but in the rest of the province there was an increase.

British Burma.

Registration of vital statistics in British Burma in 1883 still remained very imperfect. The subject, however, was under consideration during the year, and resulted in the publication of new rules, which it is hoped will lead to more reliable statistics in future. The registered births for the year numbered 83,735 or 22·92 per 1,000 against 80,848 or 22·07 in 1882, and the registered deaths 53,583 or 14·67 against 59,146 or 16·14. "It is evident," the Army Sanitary Commission remark, "that both rates (birth and death) are considerably "below the truth. Both are means for the whole country, and both include quite impossible "ratios for some of the districts." The birth-rate was made up of extremes, varying from 16·60 per 1,000 in Pegu district to 31·65 in Henzada, and the death-rate of extremes ranging from 9·22 in Tharrawaddy to 21·42 in Hanthawaddy.

Of the chief diseases, cholera showed a considerable diminution, the deaths having decreased from 7,177 or 1·96 per 1,000 in 1882 to 2,185 or 0·60 in 1883. The disease prevailed more or less in all the districts, but it was epidemic in severe form only in Akyab, Bassein, Thongwa, and Shwegyin, which together returned more than two-thirds of the total deaths. Although the disease extended over the whole province, the entire mortality took place in

only 0·85 per cent. of the villages. Some of the towns recorded very high cholera death-rates, notably Akyab, with a ratio of 4·62 per 1,000. In this town there were two outbreaks during the year; the second extending afterwards to the jail. The Sanitary Commissioner reports that segregation and disinfection entirely failed to check the disease spreading in the jail, and that it was not stamped out until the jail had been evacuated by the bulk of the prisoners. "This Akyab epidemic," the Army Sanitary Commission state, "has afforded additional "experience on the dangers that may accrue during cholera invasions from agglomeration of "people, and also the necessity of avoiding all such crowding."

The mortality from small-pox was again very low, only 675 deaths were registered, or in the rate of 0·18 per 1,000 of population against a ratio of 0·21 in the previous year. Children, as usual, were the chief sufferers, two-thirds of the mortality having occurred amongst those under 12 years of age. Six out of the 16 districts of the province were exempt from the disease, and the entire mortality was returned from only 27 of the total 14,811 villages.

Fever deaths were registered to the number of 26,283 or 7·19 per 1,000 against 27,093 or 7·39 in 1882. By districts the highest ratios were recorded in the three comprised within the Arakan division, viz., 12·02 in Akyab, 11·22 in Kyaukpyu, and 11·45 in Sandoway; in the remaining 13 districts the mortality ranged from 3·41 in Thongwa to 10·50 in Thayetmyo, both of the Irrawaddy division.

Under bowel complaints 2,781 deaths were registered or 0·76 per 1,000 against 3,291 or 0·90 in 1882. Deaths were recorded all over the province, but the whole mortality was returned from only 0·70 per cent. of the total 14,811 villages. These complaints are much more prevalent among natives of India than among Burmese. This is attributed partly to the habit of sleeping on the ground, while the dwellings of the Burmese are invariably raised several feet. "A very common cause of dysentery and diarrhœa amongst Indian immigrants "to this province is," the Sanitary Commissioner says, "starvation. Many coolies on public "works and otherwise employed here deprive themselves of the necessaries of life to enable "them to remit monthly to their relations in India a large proportion of their wages."

IV.—JAILS.

Sickness and mortality in 1883.

The health of the jail population of India in 1883 was, on the whole, very satisfactory. Compared with the two previous years and the average of the period 1877–81 the results of 1883 show a marked reduction both in sickness and in mortality. Of an average strength of 88,174, which was over 6,000 below that of 1882, the admissions into hospital, according to the Report of the Sanitary Commissioner with the Government of India, fell from 1,214 per 1,000 in 1882 to 996, the daily sick from 42 to 36 per 1,000, and the death-rate from 39·36 to 31·37. The decrease in sickness was mainly attributable to the reduced number of cases of intermittent fever, the admissions under which were in the rate of 352 per 1,000 of average strength against 513 per 1,000 in 1882. Cases of bowel complaints and respiratory diseases were also considerably less than in the previous year.

The following statement gives the sickness and mortality among the prisoners of the various provinces of India during 1882 and 1883:—

Provinces, &c.	1883. Ratio per 1,000 of Average Strength.			1882. Ratio per 1,000 of Average Strength.		
	Admissions.	Daily Sick.	Deaths.	Admissions.	Daily Sick.	Deaths.
Bengal	1,498	50	52·21	1,642	54	69·21
Madras	861	32	29·87	795	29	42·62
Bombay	734	27	34·33	843	26	33·35
Punjab	951	27	29·11	1,546	45	41·63
North-Western Provinces and Oudh	563	23	19·76	724	29	22·93
Central Provinces	919	36	70·97	966	41	71·05
Berar	558	14	8·49	449	12	8·50
Assam	2,125	56	43·12	1,735	45	33·08
British Burma	1,159	38	28·94	1,468	39	27·81

The above data, as the Army Sanitary Commission point out, show how very different are the sick and death-rates in different groups of jails. "It is true," they say, "that the facts only "apply to a single year, but they are quite sufficient to justify a recommendation that the "whole subject of current comparative death-rates, and the causes of their differences should "be inquired into. It need scarcely be stated that these local facts detract considerably from "the favourable impression produced by the year's statistics when taken over the whole "prison population."

Bengal.

For some years past, the vital statistics of the Bengal jails have been the subject of most anxious attention on the part of the Local Government, and great efforts have been made to improve the condition of the jails and of their inmates. Large sums have been spent on various sanitary improvements; the diet of the prisoners has been varied, or increased when considered advisable; better water-supply has been provided, besides many other improvements in matters connected with the well-being of the prisoners. It would seem that to some extent at least the efforts of the Government have at last been crowned with success, as for the first time since 1878 the health statistics show a very decided improvement. Of an average strength of 14,776 which was less than that of 1882 by 1,126, the admissions fell from 1,642 per 1,000 in 1882 to 1,498, the daily sick-rate from 54 to 50, and the death-rate from 69·21 to 52·21, showing a reduction in mortality of 17 per 1,000.

Amongst the convict class the admissions into hospital were in the rate of 1,600·7 per 1,000 of average strength against 1,741 in 1882, the daily sick-rate 51, or 4 less, and the death-rate 53 against 69·8. The chief causes of sickness were intermittent fevers, which contributed a third (550·7) of the total admission-rate, dysentery and diarrhœa following with a rate of 499·5. As regards mortality, the most important factors were dysentery and diarrhœa from which there were 299 deaths or 21·8 per 1,000. Cholera was considerably less prevalent than in the previous year, the number of cases having declined from 256 to 111, and the deaths from 146 to 53. Jalpigoree was the only jail in which cholera prevailed in a severely epidemic form; there it attacked 16 prisoners, chiefly new admissions, of whom 13 died. Excluding cholera, the convict death-rate is reduced to 49·2 as against 60·0 in 1882, 63·4 in 1881, 64·4 in 1880, and 80·4 in 1879. In these figures the Inspector-General of Bengal jails points out, "we have evidence of a steady improvement in the general health

" of the prisoners, and this, too, notwithstanding the facts that the health of the free " population continues to be injuriously affected by the extraordinary prevalence of malarious " fever in many districts, and the increasing prices of food grains."

As regards the mortality in individual jails, 20 recorded death-rates in excess of the average rate, but only seven showed ratios above 10 per cent., while in the previous year there were 12.

The following 10 jails showed death-rates exceeding 75 per 1,000 :—

	Death-rate per 1,000 of Average Strength.		Death-rate per 1,000 of Average Strength.
Julpigoree	261·9	Dinagepore	107·6
Lohardugga	198·0	Midnapore, *District and Central*	104·5
Rungpore	196·9	Patna	88·8
Bogra	148·0	Dacca, *District and Central*	78·8
Nuddea	118·3	Beerbhoom	78·8

With the exception of Lohardugga, all the first six jails, the Inspector-General states, " are " situated in malarious districts, and the mortality may fairly be ascribed to climatic causes." With reference to the mortality in the Julpigoree jail, which was 186·6 per 1,000 greater than in 1882, the Superintendent, in his medical report for the year, observes: " The chief causes of " sickness are shown in the return to have been bowel affections, but in nearly every case " these are merely symptomatic of a general diseased condition, the result of prolonged " exposure to malaria. It is unnecessary for me to enumerate here the conditions that " result from repeated and severe attacks of malarial fever. Suffice it to say that these " conditions are met with here in the most pronounced form, so much so, that I think it is " reasonable to suppose that these miserable broken down creatures, being unable to provide " for themselves in a legitimate fashion, degenerated from sheer necessity into the criminal " classes."

It is satisfactory to find that out of 47 jails 20 showed a decreased mortality compared with the previous year. These were the following :—

Jails.	Death-rate per 1,000.		Jails.	Death-rate per 1,000.	
	1883.	1882.		1883.	1882.

Hazaribagh, *District and Central*	43·0	64·9	Noakholly	—	51·4
Sarun	39·0	85·0	Balasore	—	40·1

It will be seen from the above that the improvement in some jails has been very considerable, especially in such notoriously unhealthy jails as Mymensingh, Chumparun, and Singhbhoom.

" The death-rate among prisoners in the jails, taken as a whole," it is observed in the Government resolution on the Report for 1883, " has much diminished; the reduction in that " from cholera may perhaps continue, and the completion of the large jail operations may " have a beneficial effect on the general health of the jail population. But in the face of the " experience of the last few years, the Lieutenant-Governor cannot hope that the mortality " among prisoners will be materially reduced until sanitary reform has reached the interior " of our districts, and there is a permanent improvement in the health of the general " population."

Madras. Amongst the prison population of the Madras Presidency sickness was more prevalent during 1883 than in the previous year, but the mortality was considerably less. The admission-rate per 1,000 of average strength was 861, and the daily sick-rate 32 against 795 and 29 respectively in 1882, while the death-rate declined from 42·62 to 29·87, an improvement which was mainly due to the great reduction in mortality at Trichinopoly central jail.

The jail death-rates varied from 7·54 per 1,000 in Rajahmundry district jail to 116·96 in Ootacamund; in 21 jails out of a total of 35 the mortality was under 50 per 1,000, and in six, including the debtor's prison, there were no deaths.

The high death-rate in the Ootacamund jail was attributed to alternations of temperature affecting gangs of men transferred from the plains, whose constitutions were shattered by malarious fever. Tanjore jail recorded the next highest death-rate (86·52), but this is stated to be an old jail, and has long been condemned. Bellary followed with a death-rate of 77·49, attributed chiefly to the inclemency of the cold weather which was unusually severe. In Cuddalore jail the mortality was high (73·70 per 1,000), the principal cause being epidemic cholera, from which there were 9 deaths out of a total of 16. The Trichinopoly jail recorded the next highest mortality, 55·14 against 176·77 in 1882. This undue mortality was the subject of special inquiry, and was traced to the bad quality of the water and to the want of sufficient care in the preparation of the ragi flour used in the jail. It is satisfactory to note that the statistics of this jail for 1884 show a further improvement. The causes of the mortality of former years was, however, still under investigation. The only other jail calling for special notice is Cannanore, where the mortality reached 41·62 per 1,000; many of the deaths in this jail occurred amongst men of advanced age sentenced to transportation, but not deported on account of infirmity.

As regards convicts the death-rate was 29·49 per 1,000 against 42·67 in 1882. Of the total 228 deaths amongst this class, 77 were due to bowel complaints, 44 to anæmia and general debility, 20 to respiratory diseases, 13 to cholera, and 8 to fevers.

Bombay.

Sickness was less prevalent among the prisoners of the Bombay Presidency than in 1882, but the mortality was slightly greater. The admission-rate in 1883 was 734, and the daily sick-rate 27 per 1,000 against 843 and 26 respectively in the previous year; but the death-rate rose from 33·35 per 1,000 in 1882 to 34·33. This slight increase was due to the prevalence of cholera, the deaths from which were twice as numerous as in 1882, viz., 15 against 7. Of the total 262 deaths which occurred during 1883, more than half (134) took place in three of the four Sind jails, viz., Hyderabad, Shikarpur, and Nara, principally in Shikarpur, where the deaths amounted to 66, equal to 101 per 1,000 of average strength. For some years past the mortality in this jail has been very high, and a source of great anxiety. In 1882 it was attributed to chills caught in the early morning; but in spite of all precautions the mortality continued to be abnormally high. The Superintendent of the jail arrived at the conclusion that the heavy mortality was due to true cerebro-spinal fever, and, in the absence of any specific cause for the disease, he attributed it to great vicissitudes of temperature, intense cold and exposure, unsuitable diet, and predisposing malarial influences. The high mortality in the Hyderabad and Nara jails was also attributed to the same disease. The Governor in Council has directed that measures should be taken to obviate the large amount of sickness and mortality in these three jails by the adoption of proper means to protect the prisoners. But while in these three jails the results were so unsatisfactory, it is gratifying to note that 16 out of the 27 jails in Bombay Presidency returned death-rates below the average for the year, and that in four jails there were no deaths. The chief causes of mortality among the prisoners were respiratory diseases which yielded 54 deaths, dysentery and diarrhœa followed with 43, fevers with 30, anæmia and general debility with 22, and cholera with 15, of which six took place in the Mhasvad gang, four in Dhulia, two in Belgaum, and one each in Yerrowda, Ahmednagar, and Kaira. All but three of the 262 deaths occurred among convicts, giving a death-rate of 34·9 per 1,000.

Punjab.

The statistics of the Punjab jails for 1883 are very satisfactory. Among all classes of prisoners the admissions to hospital were in the ratio of 951 per 1,000 of average strength against 1,546 in 1882, the daily sick-rate 27 against 45, and the death-rate 29·11 or 12·52 per 1,000 less than that of the previous year, and lower than in any year since 1871. The decrease, however, was entirely confined to convicts, for among under-trials and civil prisoners there was increased mortality. The convict death-rate fell from 43·69 per 1,000 to 29·82, showing a decrease of 13·87. As previously stated, there was very little cholera in the province during the year, and all the jails were exempt from the disease; while among all other serious diseases there was a general improvement in the jails. In the previous year the following four jails recorded the highest death-rates; but it will be seen that they all showed a marked improvement in the year under notice:—

	Death-rate per 1,000 of Average Strength.	
	1883.	1882.
Lahore, Central	66·02	113·33
Lahore, District	36·82	64·58
Amritsar	28·33	62·69
Lahore, Female	27·93	62·17

Of the total 35 jails in the province, in 22 there was a decrease in the death-rate, amounting on an average to 18·66 per 1,000 of average strength; the largest decrease being 51·50 per 1,000 at Dharmsala. In 10 jails there was an increase in the death-rate, the average excess being 15·36 per 1,000; Simla shows the highest increase, viz., 55·55. In the opinion of the Inspector-General the health of the jail population is much regulated by the general health of the province, and the cause of much of the improvement in the health of the prisoners is due to conditions external to prisons, and common to both the free and prison populations. While admitting the force of this remark, the Lieutenant-Governor considers that the unremitting care and attention to proper food, clothing, accommodation, and sanitation, which have been shown by the superintendents of the jails, have materially contributed to the improved state of things which now exist.

North-Western Provinces and Oudh.

There was also a very marked improvement in the health of the prison population of the North-Western Provinces and Oudh as compared with previous years. The admission-rate for all classes of prisoners fell from 724 per 1,000 in 1882 to 563, the daily sick-rate from 29 to 23, and the mortality from 22·93 to 19·76. Of the 461 deaths that occurred, 30 were attributed to fevers, 106 to bowel complaints, 92 to respiratory diseases, and 50 to cholera; in the previous year there were 22 cholera deaths. In the year under notice cholera was confined to the Gorakhpur, Muttra, and Agra jails, but it was most severe at Gorakhpur, where there were 57 cases of which 38 proved fatal; at Agra 11 fatal cases were recorded. At both jails vigorous measures were taken to check the disease, and the prisoners were removed to camps; but at Gorakhpur the camp had to be shifted three times before the epidemic disappeared.

Of the 52 jails in the province six recorded death-rates of over 50 per 1,000, viz., Gorakhpur 147·86, Dehra Dun 126·33, Banda 64·63, Orai 60·10, Almora 56·51, and Mirzapur 51·65; in five others the death-rates were over 30, but under 40 per 1,000. Some of these have long had a reputation for comparative unhealthiness. The average population was considerably under the number for which there was room in the jails, but at a few of the jails there seems to have been some crowding. During the year a committee sat to consider the advisability of closing the Meerut central jail, notorious for the prevalence of fever; they recommended that it should be kept open for two more years, and it was ultimately decided by Government not to allow any more prisoners to enter it, but to keep the jail on with its present inmates, and to enlarge the Bareilly and Fategarh central prisons, and to divert the future streams of convicts, which formerly flowed to the Meerut central prison, to those two jails.

Central Provinces.

The health statistics of the jails of the Central Provinces for 1883, although showing a slight improvement compared with those of the previous year, were on the whole unsatisfactory. The admission and daily sick rates were 919 and 36 respectively per 1,000 of average strength against 966 and 41 in 1882, and the death-rate was 70·97 against 71·05. This high mortality was chiefly due to bowel complaints, from which there were 163 deaths out of a total mortality of 277. Raipur and Nagpur jails again suffered most severely from these complaints, no less than 82 deaths having occurred in the former and 50 in the latter. In the Jubbulpore jail also the mortality under this head was high, 10 deaths having occurred, or a fourth of its total mortality. Out of the total 277 deaths these three central jails contributed 246, Raipur yielding 113 or 145 per 1,000 of average strength, Nagpur 92 or 110·3, and Jubbulpore 41 or 37·9. In the previous year, the high death-rate at Raipur was attributed to Kalahundi prisoners; in the year under notice the mortality in this jail was greatest amongst the Khond prisoners. "During the first six months of the year," it is reported, "the number of Khonds in hospital was always large. In July, however, 63 of "these prisoners were, on the suggestion of the Chief Commissioner, moved into camp a "short distance from the jail, and employed on out-door labour; they were also allowed "certain articles of food to which they were accustomed in their own country, and which "are not included in the ordinary jail dietary. Since then their health has rapidly improved, "and there is now no unusual sickness among them, although they have been moved back "into the jail." Cholera was present only in the Nagpur and Bhandara jails, the former yielding 10 deaths and the latter one.

Among convicts only the deaths numbered 274 or 20 less than in 1882, but the death-rate per 1,000 of average strength (73·2) was identically the same. In the Nagpur and Jubbulpore central jails the largest number of deaths in this class occurred amongst those who had been over a year in jail, while in Raipur 90 of the total 113 deaths were of convicts of less than one year's residence; of these, however, 55 were Khond prisoners.

Berar.

The health of the Berar jails was again very good, and bears witness to the attention paid to sanitary matters. Though sickness was somewhat greater in 1883 than in 1882, the admission-rate having increased from 449 to 558, and the daily sick from 12 to 14 per 1,000 of average strength, the mortality from all causes was identically the same, viz., 8·49 against 8·50. The statistics are the more satisfactory considering that the general health of the province was very unfavourable, the death-rate being 51·3 per 1,000 of population.

Nine deaths were recorded, all amongst convicts, and of these, two took place at the Amraoti central jail, five at Akola central jail, and two at the district jail of Ellichpur; at the remaining three jails in the province, Yeotmal, Buldana, and Basim, there were no deaths. Though cholera was present in all districts it did not enter the jails. Every care and attention was paid to the dieting of the prisoners, and the fact that upwards of two-thirds of the number increased in weight during their detention in jail, goes to confirm the opinion that the diet scale was amply liberal.

Assam.

The statistics of the Assam jails for 1883 are most unsatisfactory. The death-rate, which for four years had been decreasing, rose from 33·08 per 1,000 of average strength in 1882 to 43·12, the daily sick-rate also rose from 45 to 56, and the admission-rate from 1,735 to 2,125. These unfavourable results were attributed to the general unhealthiness of the year. The number of deaths was 66, of which 60 or 43·2 per 1,000 occurred among convicts against 44 or 32·3 in 1882. Of these 60 deaths, 9 were due to cholera, 23 to dysentery and diarrhœa, and 8 to general debility. The only considerable increase was in the Sylhet and Tura jails. In the former the increase in mortality from 20·3 to 52·8 is reported to have been due to an error of judgment in transferring a batch of sickly prisoners from Silchar. Orders were therefore issued that when prisoners have to be transferred from an overcrowded jail, healthy and able-bodied men should be chosen. In Tura the deaths increased from *nil* to 5 or 194·17 per 1,000 of an average strength of 26, and the entire mortality was due to the dreaded disease *kala-azar*, which was very fatal among the lower valleys of the Garo Hills (see *ante*, p. 16). Out of the 10 jails, in which there were no deaths in 1882, only four enjoyed that pre-eminence in the year under notice, besides one (South Sylhet) not included in the Report for 1882. Of the nine fatal cases of cholera, three occurred at Tezpur jail, at short intervals, at the time when the disease was prevalent in the district; two were recorded at Barpeta jail; and at the four jails of Sylhet, Shillong, Nowgong, and Silchar there were single sporadic cases, unaccompanied by any epidemic.

British Burma.

The results among the prisoners of British Burma in 1883 were much the same as in the previous year. The admissions to hospital were somewhat smaller, being in the ratio of 1,159 per 1,000 against 1,168 in 1882; the daily sick-rate remained the same, 39; but the death-rate rose from 27·81 to 28·94. This increase in mortality was due to the outbreak of epidemics of cholera at Akyab and Kyaukpyu, resulting in 26 deaths at the former and 15 at the latter. All the other jails were exempt from this disease except Ma-ubin, where there was one fatal case. Of the 14 jails in the province, Kyaukpyu recorded the highest death-rate, 169·23 per 1,000, of which 115·38 was due to cholera; Akyab followed with 132·02, nearly a half being caused by cholera; Mergui followed with a death-rate of 71·43, Ma-ubin with 49·50, and Henzada with 46·05. In none of the other jails was the provincial average exceeded, while in three jails there were no deaths. Of the total 155 deaths, all but four occurred among convicts, the death-rate per 1,000 of average strength being 29·60 against 26·4 in 1882. As in previous years, the greatest number of deaths occurred among newly admitted convicts. The average number of deaths among those who had been less than six months in jail was 57·55 per 1,000 against 62·2 in 1882, and of those who had been more than six but less than twelve months in jail, 25·51 per 1,000. Of the total number of deaths, 111 or 73·51 per cent. occurred among convicts who had been in jail less than a year. "It is possible," the Chief Commissioner observes, "that the slight decrease in the average "number of deaths among convicts recently admitted may to some extent be due to the "abolition of the reduced ration for short-term prisoners. The fact that the number of "prisoners who weighed more on release than they did on admission was nearly three times "as great as that of those who lost weight, speaks well for the general good health of the "prisoners."

V.—VACCINATION.

Fair progress was made in vaccination work in Bengal during 1883–84. The operations of the Government vaccinators were extended for the first time to portions of the Monghyr, Tipperah, Chumparun, Shahabad, and Gya districts, comprising an area of 6,179 square miles, with a population of 3,800,388; besides this an area of 4,416 square miles, containing a population of 1,916,568, was for the first time placed under the licensed system of vaccination. At the close of the season the thoroughly protected areas comprised 37,969 square miles, with a total population of over 15,000,000. The vaccination staff was considerably strengthened during the year, and resulted in the increase of the operations performed from 1,261,425 in 1882–83 to 1,361,332, and in the successful cases from 1,229,058 to 1,329,628. The increase, however, was not general, for in the Metropolitan, Darjeeling, and Sonthal Pergunnahs circles, there was a large decrease, especially in Darjeeling. The primary operations numbered 1,350,519, of which 98·66 per cent. were returned as successful, against a corresponding percentage in the previous year of 98·60. Of the total 1,324,853 successful primary operations, 178,487 were performed on infants under one year of age, and 877,338 on children between the ages of one and six years. It would thus appear that infants are very inefficiently protected from small-pox. By assuming a birth-rate of 30 per 1,000 the Sanitary Commissioner of Bengal calculates the births at 1,448,895, of whom only 12·32 per cent., exclusive of those who died, were successfully vaccinated. "Apart from "several other causes," the Sanitary Commissioner states, "the main reason why a larger "ratio of protection is seen among children above one and under six years of age than among "infants is that parents or guardians (particularly mothers) greatly fear to expose children "of tender age to vaccination, which is considered to be attended with much risk." Bengal.

The Compulsory Vaccination Act of 1880 was extended during the year to 56 towns and four thannahs. But little opposition was made to its operation; in fact, public feeling generally is said to be growing in favour of vaccination, though opposition, chiefly on religious grounds, is still exhibited. In Gya, for instance, where the town Act had been previously extended, obstinate resistance was made by the wealthy class of Hindus and the priests of the old town. The protection afforded by vaccination may be gauged by the fact that, while the mortality from small-pox in unprotected areas was ·23 per 1,000, in the thoroughly protected areas it was only ·07 per 1,000.

One interesting feature in connection with the vaccination administration was the great increase in the use of bovine lymph. It is reported that the demands for it during the year were so numerous that the establishment was barely able to cope with them. In no less than 1,352 instances the calf was required to be taken for vaccination to the houses of private persons, and the question was raised whether a fee should be charged in such cases in order to meet the expenditure involved. The Sanitary Commissioner considered that it was fully time that the bovine vaccination scheme should be made a permanent institution, and the Lieutenant-Governor expressed his willingness to consider any specific proposals that might be made with this object.

Progress was also made in vaccination in the Madras Presidency, but not sufficient to keep pace with the growth of the population. During 1883 there were 753,589 persons vaccinated, being an increase of 88,921 over the previous year. Of the total number, 736,662 were primary operations, of which 683,384 or 92·7 per cent. were successful, the highest percentage shown during the previous 10 years. As in 1882 children over one and under six years of age were the most largely protected, the number of successful cases being 334,623, and infants the least, only 131,371 having been successfully vaccinated during the year. In a great measure this is accounted for by the objections mothers have to early vaccination. It is reported that "on the appearance of the vaccinator in a village it is a "common custom for parents to send their children away to a neighbouring hamlet, and "stoutly deny having any." On the whole, however, the results as regards infants compare favourably with 1882, the successful vaccinations being in the ratio of 16·6 per cent. of the total births against 15·7. In some districts inoculation is said to be very much practised and greatly preferred by the people to vaccination. As it interferes greatly with the progress of vaccination, the Inspector of Vaccination has suggested that an Act should be passed prohibiting inoculation in those districts where vaccination can be had. Madras.

Animal vaccination was carried on during part of the year in the Madras, Guntur, and Tanjore circles, and was to be started in 1884 in other circles. In the Guntur circle animal vaccination was rendered necessary in order to keep up a supply of good lymph, as the people would not allow lymph to be extracted from their children's arms.

Bombay.

In the Bombay Presidency the total vaccinations performed during 1883–84 amounted to 883,839, being an increase of 25,128 on the number of the previous year. Of these 826,965 were primary cases, with a percentage of success of 95·69 against 96·15 in 1882–83. Satisfactory progress continued to be made in the protection of infants. Out of every 100 persons primarily vaccinated there were 60·98 infants, of whom 58·58 were successfully vaccinated. Compared with the results of the previous year this percentage is lower by 0·57, but the decrease is only apparent because the difference between the numbers vaccinated and the successful cases was higher by 0·15 per cent. The protection of infants is further shown by comparing the number successfully operated on with those available for vaccination at the rate of 31 per 1,000 of population, when it is found that 61 per cent. were successfully vaccinated against 59·01 in 1882–83, and a five years' average of 48·86. In Bombay City animal lymph only was used, and in Poona, Broach, Nadiad, Anklesvar, Borsad, Rajkot, and Dhrangadra, both animal and human lymph were in use. Vaccination with animal lymph was also carried on in Bandra, and its introduction into the town of Belgaum and the municipal towns of the Satara Collectorate was under contemplation. In all other places vaccination was carried on with human lymph.

The Compulsory Vaccination Act continues to work fairly in Bombay City, and also in the town of Karachi. With the view of encouraging good work amongst vaccinators, steps were being taken to introduce a system of remuneration to the most deserving officers. A scheme was under consideration for forming a class for instruction in vaccination at Karachi.

Punjab.

The statistics of vaccination in the Punjab for 1883–84 testify to the energy shown in the cause by the authorities. The aggregate number of operations performed during the year was 633,062, being an increase of 133,365 over the number of the previous year. Primary operations numbered 624,873, of which 94·25 per cent. were successful against 95·11 in the previous year. Of the 588,761 successful primary cases, about two-thirds (426,253) were infants under one year of age, and 152,034 were children between the ages of one and six years. The number of persons successfully vaccinated during 1883–84 per 1,000 of population was 31·08, or 6·01 higher than in 1882–83; and of children born during the year 58 per cent. were protected by vaccination. Out of 32 districts all but seven showed an increase in vaccinations, but in three the decrease was very trifling. The increase was most marked in Kangra (13,598), and Hoshiarpur (8,228); in four others the increase ranged from 7,578 to 6,573. The increase in the several districts is considered a hopeful sign of the growing popularity of the re-organised vaccination scheme instituted in 1881. "It is also "evident," the Lieutenant-Governor states, "that the advantages of vaccination are beginning "to be felt, and that the prejudices against it are gradually giving way." Two facts alone point to this conclusion, viz., the Amritsar Municipal Committee renewed their application for vaccination to be made compulsory, which was sanctioned; and the application by the Raja of Bashahr for the services of a large staff of vaccinators to carry on operations in his State.

North-Western Provinces and Oudh.

The statistics of vaccination for the North-Western Provinces and Oudh for 1883 indicate a lower degree of success than in previous years; but this is accounted for chiefly by the discontinuance of a system that had been prevalent in Oudh of making fictitious entries. The total operations performed during the year amounted to 649,067, being 23,576 less than the number of 1882. Of these 565,351 or 92·11 per cent. were successful primary cases, less than a half (264,496) being children under one year of age, representing less than 15 per cent. of the registered births. "It is not difficult to see," the Army Sanitary Commission observe, "where "the defects of the vaccination are to be found, and where a remedy has to be applied so "far as it might by itself lessen liability to small-pox, and this lies in directing the work of "the service as much as possible to the protection of infants under the first year of life, "when small-pox is most fatal, and when the protection, once secured, passes onwards to "after life."

The province is divided into three vaccination circles. In the first, comprising the 13 districts of the Agra and Meerut divisions, there was a considerable increase in the number of operations, the successful primary vaccinations having risen from 192,369 in 1882 to 216,044, showing an increase of 23,675, which was spread over all the districts excepting Mainpuri and Muzaffarnagar, where there was a slight decrease. In the second circle, comprising the Oudh, Rohilcund, and Kumaun divisions, there was a most unsatisfactory decrease in the successful primary vaccinations from 164,377 in 1882 to 128,000. This shows a decrease of 36,377 cases, which was spread over all the 22 districts contained in this circle but one, Bara Banki, where the number rose from 2,561 to 5,699. In the third circle, embracing the Allahabad, Benares, and Jhansi divisions, there was also a decrease of 20,853 successful primary cases, the total number for the year being 221,307 against 242,160 in 1882. This decrease was spread over 12 of the total 16 districts, but chiefly in the

Cawnpore and Muzaffarnagar districts, the former showing a decrease of 8,856, and the latter 5,818; the decrease is attributed in some places to paucity of subjects, and in others to want of encouragement on the part of the local authorities. On the whole, however, considerable assistance appears to have been rendered by the local authorities and private gentlemen in extending vaccination.

Central Provinces.

Vaccination work in the Central Provinces during 1883–84 was not attended with such satisfactory results as in the previous year, the total number of operations having declined from 433,691 to 421,542, showing a decrease of 12,149. Of primary vaccinations 409,636 were performed, of which 97·19 per cent. were successful against 96·94 in 1882–83. Out of 357,864 children born during the year, 177,429 were protected by vaccination, or at the rate of 49½ per cent. Eleven districts out of 18 showed a decided falling off in primary vaccination, and in one, Chanda, the decrease was small. The most marked decrease was in Balaghat, where the number fell from 18,068 to 9,492, which the Civil Surgeon attributed "not so much to a failure to vaccinate the children under one year available this season, as "to a larger number of children over one year having been vaccinated last, leaving fewer of "that age available this." Six districts showed an increase in primary cases, the largest being in Sambalpur, where they rose from 21,670 to 27,392. During his cold weather tour the Sanitary Commissioner inspected a number of vaccinated children, and in two circles he found that the vaccinators had almost entirely neglected their work. "The points," he says, "that appeared to me most calling for attention by civil surgeons are, that any cicatrix if "well marked was considered by many vaccinators evidence of successful vaccination, they "not distinguishing between the typical cicatrix and that caused by ulceration; and, secondly, "that sufficient attention is not paid to the number of vesicles or marks, but that one or two "small vesicles or marks are not infrequently accepted as proof of successful, that is, "protective vaccination. Thus parents are led to believe that their children are protected "when they are really not, and an attack of small-pox causes them and their friends to lose "faith in vaccination."

Berar.

The results of vaccination in Berar during 1883–84 show a very considerable decrease, amounting to 2½ per cent. in the number of operations, as compared with the previous year. This serious decrease was attributed partly to the introduction of a new system of organizing the department, whereby the number of vaccinators has been tentatively reduced from 54 to 42, while they are kept at work for 10 months of the year instead of for only six months as heretofore; and partly to the paucity of subjects due to the exceptionally high mortality among children. The total number of operations performed was 86,721 against 110,786 in 1882–83, and the primary cases numbered 86,471, of which 92·69 were successful, a higher rate by 1·1 per cent. than in 1882–83. But although there was such a falling off in the number of operations, satisfactory progress was made by the Vaccination Department in infantile vaccination, no less than 70¼ per cent. of the total successful cases being infants under one year of age against 61·3 in the previous year. Estimating the births at 40 per 1,000 of population, the number of infants successfully vaccinated during the year was 53·09 per cent. There appears to be but little opposition to vaccination; the people are, however, apathetic, and a little pressure is sometimes necessary to make them bring up their children for vaccination. In some of the larger towns much difficulty is experienced amongst Marwadis and Mahomedans, and the only remedy, in the opinion of the Superintendent of Vaccination, is the extension of the provisions of the Vaccination Act to Berar. Municipalities were invited to consider the question of compulsory vaccination, and the committees of Khamgaon, Shegaon, Akola, and Basim passed resolutions for the introduction of a bye-law making vaccination compulsory within their limits. The matter was still under consideration in the municipalities of Amraoti and Ellichpur.

Assam.

Great progress was made in vaccination work in Assam during 1883–84. The total operations numbered 88,693, which is an increase of 30,854 on the number of the previous year, and of 43,447 on that of 1881–82, when first a marked improvement manifested itself. With the exception of 570 cases all the operations were primary, and of these 76,368 or 86·66 per cent. were returned as successful. All the districts showed an increase except Darrang, where there was a falling off by 3,522 cases. In the tea gardens considerable advance was made, the total operations having increased from 2,243 in 1882–83 to 10,336; but of these only 51·2 per cent. were successful. Of the total successful primary cases, 12,035 were infants under one year, and 39,820 were children between one and six years of age. The protection afforded to children born during the year was in the proportion of 11 per cent. No active opposition to vaccination is shown by the people generally, but it would appear that religious prejudices, especially among the higher classes,

interfere with the spread of the cause. "The influence of the Goshains and other heads of "religious establishments," it is stated in the Resolution of the Local Government on the Vaccination Report for 1883-84, "is a factor in the social and moral life of the Assamese "which has never been thoroughly fathomed or properly understood, and the whole of that "influence (with very few exceptions) is directed against vaccination. . . . Large sections "of the community are, no doubt, free from this religious subjection, and it is among them "that vaccination makes progress; but among the classes higher in the social scale it can "make little advance till some means are found of diverting the opposition of the Goshains, "or till the superstitious veneration in which they are held melts away."

British Burma.

Some progress was made in the work of vaccination in British Burma during 1883-84. The total number of operations performed by the vaccination staff was 73,269, or 18,174 more than in the previous year. Of these 61,901, or 84·48 per cent., were successful cases against a percentage of 84·11 in 1882-83. According to age only 8,831 of the successful cases were infants under one year of age, representing about one-ninth of the registered births; while 33,220 cases were between one and six years. At the dispensaries only 28 operations were performed, 17 being successful. The Sanitary Commissioner complains that the influence of the medical officers in charge of these institutions for the advancement of vaccination is very far from being utilised; the Government of India have therefore directed that civil surgeons should be enjoined to devote special attention to the matter. Much good work, however, appears to have been done by independent vaccinators. Possibly, the Chief Commissioner observes, the total of such outside operations may have been 20,000. Under the direction of one gentleman (the Rev. Dr. Vinton, an American missionary) over 8,000 Karens were reported to have been successfully vaccinated.

VI.—MEDICAL INSTITUTIONS.

Civil Hospitals and Dispensaries.

Considerable changes were made during 1883 in the administration of charitable dispensaries in Bengal. A large number of these institutions was transferred to the management of municipalities, new ones were opened, and others which had been closed as useless or for financial reasons were re-opened. The old system, under which Government guaranteed an appointment as assistant surgeon to every student passing the licentiates' examination, was found to cause an accumulation of unemployed assistant surgeons, and was brought to an end. For the purpose of adjusting the pay of medical officers at sub-divisions, all sub-divisions were graded in seven classes, according to the work in each, and arrangements made for posting to them medical officers from the grade of surgeon for the highest class to that of assistant surgeon for the intermediate, and of hospital assistant for the lowest class of sub-division. The managers of dispensaries are allowed to utilise the services of the sub-divisional medical officers on payment of the dispensary allowances, or to secure the services of an officer of a higher grade on making up the difference of the grade pay and allowances. At the close of 1882 the number of dispensaries that remained open was 223. In the course of 1883 11 institutions were newly established, and four were closed or abolished, leaving 230 open at the close of the year. Of these 102 were managed by municipal bodies, and 101 by special committees. The total number of patients under treatment was 938,221 against 957,623 in 1882; of in-patients there were 22,468 and of out-patients 915,753 against 23,468 and 934,155 respectively in the previous year. The death-rate among the in-patients was 141·3 per 1,000, less by 16·2 per 1,000 than in 1882, and lower than in any of the previous six years. Bengal.

The charitable dispensaries do not appear to be largely resorted to by the people even in times of epidemics. The value of European medical science is, however, becoming more felt, and it is hoped that as local bodies interest themselves more in the management of the dispensaries the people may be brought to place more confidence in them.

The income of the institutions in 1883 amounted to 45,175*l.*, of which 3,951*l.* were contributed by Government, and 13,375*l.* were subscriptions from Europeans and Natives, those of the latter amounting to 11,571*l.*; the remainder was made up chiefly of municipal and other local funds. The expenditure of the year, including 1,747*l.* invested, was 37,781*l.*, and the cash balance at the end of the year was 7,393*l.*

Although, on the whole, the health of Calcutta in 1883 was more satisfactory than in the previous year, the evidence of the hospitals was not in accord with that of the general town record. The total number of patients rose from 253,083 in 1882 to 259,718, an increase of 6,635. The increase, however, was entirely among out-patients, as shown in the following table, and was attributed to the fact that cases of lighter illness were more common during the year.

Medical Institutions.	1883.				1882.			
	Total Treated.			Died per 1,000 of treated.	Total Treated.			Died per 1,000 of treated.

* Reckoned on the cases treated, exclusive of ophthalmic cases.

Among the in-patients there were 2,719 deaths, or 136·83 per 1,000, a lower rate than in any of the previous seven years, and this notwithstanding that the number of cholera cases treated in 1883 was larger, and the disease was attended with full measure of fatality. Excluding cholera, the death-rate was 116 per 1,000, lower than in any year since 1876. Of the chief diseases among in-patients there were 932 cholera cases, 510 of which proved fatal; fever cases numbered 3,843, and the deaths 299; from small-pox there were 111 cases and 35 deaths; and for dysentery and diarrhœa 2,428 patients were treated, of whom 734 died. Of other diseases phthisis accounted for 192 deaths, and respiratory affections 151. It will thus be seen that these six causes accounted for more than two-thirds of the total mortality. In major surgical operations there was an increase of 160, compared with the results of

1882, the total number performed being 1,160. Including the cases under treatment from the previous year the number was 1,253. Of these 786 were cured, 213 were relieved, 61 were otherwise discharged, and 108 ended in death. The number of minor operations performed during the year was 15,873 against 17,707 in 1882.

The total income of the Calcutta hospitals in 1883 amounted to 43,170*l.*, of which Government contributed 26,232*l.*, and the total expenditure for the year was 40,870*l.*

Madras. The number of hospitals and dispensaries in the Madras Presidency increased in 1883 by 12, the total being 287 against 275 in 1882. Of these only 18 were State institutions, constituting the first class; 255 were local fund and municipal institutions, or second class; while 14 others were private institutions, 8 being aided by Government or local bodies. The total number of patients under treatment during the year was 1,696,809, being an increase of 158,233 on the number of the previous year. More than a third of the total number of patients were females. "If the conservative habits of the people be taken into "consideration," the Surgeon-General remarks, "it must be gratifying to see European "medicine making such steady and increasing progress amongst the female portion of the "population; and if the amount of private practice of medical officers amongst the more "respectable Hindu families, who do not usually apply at public hospitals, be added, the "proportion would be found to be still more satisfactory." The increase was, as usual, chiefly among out-patients, the in-patients having risen only from 37,456 to 38,447. Of these 2,903 or 75·5 per 1,000 died during the year against a mortality of 71·6 in 1882. As already shown the public health was not satisfactory. Cholera was epidemic more or less throughout the southern parts of the Presidency, and the cases treated at the dispensaries rose from 10,131 in the previous year to 10,384 in 1883; of these 452 were in-patients, of whom 239 died. Small-pox patients increased, while cases of venereal diseases and malarial fever were not so numerous as in former years; on the other hand there was a considerable increase in skin diseases and ulcers. Surgical operations again showed a decided advance, those of a major kind having risen from 2,811 in 1882 to 3,262, and the minor operations from 39,405 to 45,918. These gratifying proofs of native confidence in operative surgery are due in a great measure, the Surgeon-General points out, to the dispensaries being "now to a larger "extent under the management of men practically qualified in the several branches of "their profession, and the number of surgical operations is the result of employing more "largely the class of civil apothecaries, instead of hospital assistants, for the charge of local "fund hospitals."

The total income of the institutions declined from 81,106*l.* in 1882 to 80,354*l.* of which 28,864*l.* represented contributions from Government. Native donations and subscriptions fell from 1,783*l.* to 1,138*l.*

Bombay. During 1883 four new dispensaries were opened in the Bombay Presidency and one was closed; at the end of the year there were 202 institutions in operation against 199 in 1882. The total number of patients under treatment was 1,372,249, of whom 36,255 were in-patients and 1,335,994 out-patients against 35,111 and 1,285,074 respectively in 1882. There was thus an increase of 1,144 in the number of the former class of patients and of 50,920 in the latter in 1883. Of the in-patients 24,801 were cured, 3,099 were relieved, 2,979 were otherwise discharged, and 2,559 or 70 per 1,000 died against a ratio of 71 per 1,000 in the previous year. Malarious fevers, as usual, were the chief causes of admission, being in the proportion of 18·3 per cent. of the total treated for all diseases against 19·2 in 1882; skin diseases came next with a percentage of 12·8 against 12·3; diseases of the eye followed with 9·4; worms 7·6 against 7·2; and respiratory diseases 5·6 against 5·2. Cholera cases rose from 2,520 in the preceding year to 6,215, of which 5,083 were treated in the Deccan, where the disease was most prevalent during the year; 605 in the Konkan, and 527 in Gujarat. Of small-pox there were 845 cases treated against 128 in the previous year. The figures for cholera and small-pox, however, in no way represent the actual extent of these diseases, as all the cases are not taken to hospitals and dispensaries for treatment.

In surgical operations there was an increase of 7,428, the total number being 79,815 against 72,387 in 1882. The increase, however, was entirely under minor operations, and was due to the fact that many of the operations heretofore entered as major were classed as minor in 1883. The number of major operations performed during the year was 4,393, which added to the 147 under treatment at the beginning of the year gives a total of 4,540 against 4,571. Of these 3,918 were discharged as cured, 152 were relieved, and 179 died.

The net income of the institutions for 1883 amounted to 98,177*l.* against 96,587*l.* in 1882. Of this sum 77,897*l.* were contributed by Government, and 17,950*l.* were from local and municipal funds, while the receipts from private subscriptions amounted to only 846*l.* against

1,758*l.* in 1882. The attention of Collectors has been directed to the expediency of inducing the public to subscribe more liberally towards the support of dispensaries. The total expenditure, exclusive of 1,660*l.* invested during the year, amounted to 92,329*l.* against 90,306*l.* in the previous year.

Punjab.

The year 1882 closed with 189 dispensaries at work in the Punjab. During 1883 four new institutions were opened and two were closed; there were therefore 191 open at the close of the year. At these 38,016 in-patients and 1,560,240 out-patients were treated against 38,619 and 1,578,405 respectively in 1882, showing a decrease among both classes of 18,768. The decrease, however, was viewed with satisfaction, as it was attributed to the general healthiness of the year. Of the more important diseases under treatment, malarious fever cases numbered 269,254, or less by 84,447 than in 1882, the largest decrease being in the districts which had previously suffered so severely from inundations; ulcers formed the most numerous class of patients after fevers, followed by respiratory diseases, both showing a considerable increase compared with the previous year. As in previous years ophthalmia prevailed to a great extent, and would appear to be steadily increasing. The matter was receiving special attention, and civil surgeons of districts where ophthalmia was prevalent were invited to offer an opinion on the subject. The number of cases rose from 90,320 in 1881 to 113,789 in 1882, and to 115,207 in 1883. Of small-pox cases there were 245, and of cholera 113; of the latter 103 were fatal. Among the in-patients there were 2,041 deaths, the ratio per 1,000 of total treated being 53·7 against 56·0 in 1882. A striking proof of the usefulness and popularity of the Punjab dispensaries is the increase in the number of surgical operations which rose from 107,216 in 1882 to 121,895 in 1883. Of these 6,646 were of the major kind, an increase of 1,499 on the number for 1882. The Surgeon-General testifies to the satisfactory working of the hospitals and dispensaries as a whole. Excellent work is reported to have been done at the Mayo and Egerton hospitals; the latter is said to be popular, not only among the inhabitants of the city of Peshawar in which it is situated, and surrounding territory, but also beyond the border, a number of Afghans having applied for relief during the year.

The income from all sources amounted to 44,667*l.* against 37,771*l.* in 1882, of which 35,680*l.* were derived from local and other funds. The expenditure amounted to 44,261*l.* against 36,111*l.*

North-Western Provinces and Oudh.

The number of hospitals and dispensaries in the North-Western Provinces and Oudh for which statistics were furnished in 1883 was 212; of these 202 were supported by provincial and local funds, and 10 were chiefly supported by private individuals, but aided by provincial funds; besides these, 22 institutions, supported entirely by private individuals, were at work during the year, the results of which are not given. The returns of the 212 institutions showed that 1,525,172 patients sought out-door relief, a decrease of 128,295 on the number of 1882; and that 42,284 were in-door patients, a decline of 1,347 on the number of the previous year. The causes assigned for the decrease was the exceptionally healthy character of the year and the more faithful record of cases treated. Of the total patients 2,148 or 0·14 per cent. were under treatment for cholera, 13·11 per cent. for fevers, 19·89 for skin diseases, 6·48 for respiratory affections, 5·36 for rheumatism, 5·75 for ophthalmia, and 4·48 for dysentery and diarrhœa. The deaths among the in-patients fell from 3,360 or 77 per 1,000 of the total number in 1882 to 2,549 or 60 per 1,000 in 1883. The progress in surgery continued to be satisfactory. Altogether 91,371 operations were performed, of which 12,968 were major against 10,613 in 1882, and 78,403 were minor against 76,492. Of the major operations 4,882 were cataract cases, and of these 3,346 proved successful, the patients acquiring good sight.

Excluding balances, the total dispensary income of 1883 was 37,844*l.* against 40,299*l.* The amount contributed by Government fell from 17,186*l.* to 1,044*l.*, the decrease resulting from the transference of the control of the majority of the institutions from the State to local bodies. The expenditure amounted to 39,431*l.* against 38,511*l.* in 1882.

Central Provinces.

The number of charitable dispensaries open in the Central Provinces during 1883 remained the same as in the previous year, viz., 82, all being practically maintained by local funds. The number of cases treated was 611,541, an increase of 18,698 on the total of the previous year; the increase was solely under out-patients, in-patients having decreased from 7,895 in 1882 to 7,545. The decrease in in-patients was consequent on a more careful and discriminate selection of cases. The most prominent diseases under treatment were fevers, but there was a decrease of 872 cases on the number of the previous year; in cholera cases there was an increase of 984; and there was a marked increase under all the more common diseases. In cases of ophthalmia there was the very large decrease of 8,321, while in 1882 the cases were 17,221 in excess of the number of 1881. Each year witnesses to an increase in surgical

operations, the major kind were 143 above the number performed in 1882, and the minor class 1,564 in excess. The deaths among the in-patients numbered 824 or 109·2 per 1,000 of total treated against a ratio of 121·0 in the previous year. On the whole the results of the year were considered satisfactory; and dispensary treatment appears to be gaining in popularity among women; it is reported that women and children now resort to dispensaries in increasing numbers.

The total receipts of the institutions during 1883 amounted to 11,671*l.*, of which Government contributed 4,479*l.*; the expenditure was 11,185*l.*

Berar.

There was an addition of five new dispensaries to the 36 open in 1882, making a total of 41 at work during 1883. At these 195,364 persons sought relief, which is an increase of 14,354 on the number of the previous year. In-patients numbered 2,137, or 46 more than in 1882. The year being an extremely unhealthy one a general increase in attendance at the dispensaries was anticipated, but except in a few institutions it was inconsiderable. As already stated, cholera was very prevalent in the province in 1883, and much good work appears have been done in the way of relief. In all there were 4,697 cases under treatment against 783 in the previous year. Further relief was also provided by a special staff of additional medical officers dispersed through the villages where the disease was most rife. Amongst in-door patients fevers, injuries, dysentery, rheumatic and chest affections, diarrhœa, abcess, and ophthalmia were the principal causes of admission, and excepting injuries and rheumatic affections, these also constituted the chief diseases for which out-patients were treated. There were 106 deaths among in-patients, being in the proportion of 49 per 1,000 of the total number against a ratio of 52 per 1,000 in 1882. As regards operations, the results of the year were satisfactory. The number performed was 291 major and 7,060 minor operations as compared with 266 and 7,546 respectively in the year previous.

The income of the institutions for the year, excluding the opening balance, amounted to 10,527*l.* against 10,841*l.* in 1882. The income was materially augmented by the large increase of 643*l.* in subscriptions and donations from Natives; on the other hand there was a falling off of 730*l.* in the amount received from local funds. Of the total receipts 7,673*l.* were contributed by Government. The expenditure, excluding sums invested, amounted to 8,962*l.* against 9,526*l.* in the previous year.

Assam.

There were 29 dispensaries working in Assam during 1883; four only, in the hill districts, were supported by Government, and two were managed entirely by private persons, with a small contribution from Government, while the remaining 23 were supported by local boards. Several others were also opened by the local boards in the Sylhet district, but they were hardly in working order by the end of 1883. These new institutions are mainly supported by local funds, but in some the Government had agreed to appoint a hospital assistant, while others were to receive European medicines free of cost. The number of patients treated during 1883 amounted to 77,560, of whom 3,294 were in-door and 74,266 out-door patients against 3,229 and 61,523 respectively in 1882; there was therefore a total increase in the year under notice of 12,808 patients. Fevers and skin diseases were the principal diseases treated, but want appears to have been at the bottom of most illness, and generous diet is reported to have done more for the patients than medicines. The number of deaths among the in-patients rose from 589 or 182·4 per 1,000 in 1882 to 666 or 202·2 in the year under report. The total number of operations performed during 1883 was 2,472 against 2,463 in the previous year. Of these 148 were major operations, being an increase of 4 on the number of 1882. The Sanitary Commissioner considered that operative surgery in the various dispensaries would be greatly increased if the dispensaries themselves were, as a rule, more suited to receive surgical cases. "It too often happens," he states, "that the surgical relief "of a district falls into disuse, and even into disrepute, through the simple fact that the "dispensary wards and their occupants are in such an insanitary condition that the "superintendents are justified in refusing operative cases." The Chief Commissioner directed the attention of the authorities to this matter, and hoped that they would introduce such reforms that the Sanitary Commissioner might not have to record so unfavourable an opinion in his next report.

The total income of the institutions amounted to 5,632*l.* against 4,351*l.* in 1882; and the expenditure, exclusive of sums invested, was 5,257*l.* against 3,927*l.* One satisfactory feature in the year's receipts was the increase in subscriptions from Europeans and Natives from 1,281*l.* to 1,501*l.*

British Burma.

Each year testifies to the popularity and usefulness of the hospitals and dispensaries in the province of British Burma. The number of these institutions open in 1883 was 28, the

same as in the previous year, but the number of patients under treatment increased from 134,176 to 151,073. Of these 137,641 were out-patients and 13,432 were in-patients. Nearly half the total number were natives of India, a circumstance which is attributed to the fact that, with one exception, all the hospital assistants are natives of India, most of them being very imperfectly acquainted with the Burmese language, and that the medical officers in charge of districts are all either Europeans or natives of India. Efforts, however, were being made to train Burmans to fill these appointments. With this object six students were studying in Calcutta for the assistant surgeon grade, and six pupils, candidates for appointment to the hospital assistant grade, were under training in Madras. In the event of this experiment proving successful a wider appreciation of the advantage of the European system of medicine is anticipated among the natives of Burma. During the year 329 major and 3,863 minor operations were performed against 193 and 3,128 respectively in 1882. It is satisfactory also to note that the obstetric cases rose from 152 in 1882 to 212 in 1883. Of the 13,432 in-patients 7,918 were cured, 827 relieved, 528 otherwise discharged, and 1,197 or nearly 90 per 1,000 died. In several of the hospitals considerable improvements were effected during the year, and four new dispensaries were in course of construction.

Lock Hospitals.

In the exercise of the discretion granted by the Secretary of State, the Government of India ordered the suspension in Calcutta of the Contagious Diseases Act from the 15th March 1883; arrangements were, however, made through the Surgeon-General for maintaining the lock hospitals at Alipore and Sealdah for the treatment of venereal disease as purely voluntary institutions. The results of the first year's working of these two hospitals on this basis show that on the day previous to the suspension of the Act there were 146 Native women under treatment in the Alipore and six in the Sealdah hospital. The day following the suspension of the Act all but five of the women in the former hospital demanded to be discharged and were set free; while in the latter every woman remained voluntarily until she was cured. It is stated that the scare among the Native women was due to a report by some evil-disposed person that those women who remained voluntarily in the hospitals would not be allowed to leave even when cured. Only by degrees was the true nature of these voluntary hospitals learnt by the Native women. The daily monthly average of attendance in the hospitals increased from 6·9 in April to 58·8 in August, and then fluctuated from 42·5 in October to 52·4 in December. Bengal.

The Surgeon-General (Dr. Payne), when subsequently reporting on the results of the above measure during the remainder of 1883, expressed his most decided opinion against the policy of withdrawal, stating that the measure had in the course of nine months undone all the good that had been accomplished. The statistics furnished by Dr. Payne apparently show that the withdrawal of the Act had resulted in injury to the health of certain classes of the population. On the other hand, as stated in the Resolution of the Bengal Government, "it must be "remembered that other evils which the Native public regard as substantial have been "removed. It would be premature to decide, after an experience of only nine months, "on which side lies the balance of advantage. If, after a sufficiently prolonged experience, "it should appear to the Lieutenant-Governor that the health of the population of Calcutta "and the garrison of Fort William demands the surrender by the women of the town of so "much of their personal liberty as is curtailed by the strict enforcement of the Act, "Mr. Rivers Thomson will not hesitate to bring the matter again under the consideration of "the Government of India."

As regards the working of the four cantonment lock hospitals in Bengal, the results obtained at Barrackpore and Dum Dum were far from satisfactory; while the returns for Darjeeling show a considerable decrease in the number of admissions, and those for Dinapore exhibit a slight improvement.

At Dinapore the total admissions among the troops were 135 or 145·16 per 1,000 of an average strength of 930 against 149 or 162·8 in 1882. The favourable results of 1883 were again attributed to the manner in which the duties of supervision and examination were performed. At the beginning of the year 65 women were on the register, 22 were added in the course of the year, and 18 names were struck off, leaving 69 on the roll at the close of the year. There were altogether 230 admissions among the women, or 62 more than in 1882, the increase being attributed to the prompter and more frequent detection of disease.

Among the troops stationed at Barrackpore, there were 66 cases of venereal disease, being in the proportion of 268·2 per 1,000 of average strength against 241·56 in 1882. Of the total cases 37 were of primary syphilis. It is reported that the Cantonment Committee were of opinion that it was impossible to check venereal disease among the troops at Barrackpore while the Contagious Diseases Act was not in force in Calcutta and Serampore; and that, though clandestine prostitution probably takes place locally, it was difficult to detect it. The

proximity of Calcutta, it is observed in the resolution of the Local Government, no doubt enhances the difficulty of protecting the troops in cantonments, and the consequences of the complete withdrawal of the Contagious Diseases Act are reflected in the returns from Barrackpore and Dum Dum. The average number of women on the register during the year was 29; and the number of admissions to hospital was 72 against 64 in 1882; but only 10 cases were reported as being of a specific infecting character.

At Dum Dum out of an average strength of 763 troops, 282 or 369·59 per 1,000 were admitted to hospital on account of venereal disease against 151·6 in 1882; of these, 156 were for primary syphilis. This great increase was attributed to the infrequency of examination of the registered women and to the probable existence in the neighbourhood of unregistered women. With a view to put down unlicensed prostitution in the cantonment, it was suggested that a special police force should be employed experimentally for one year for the detection of prostitutes; but the Lieutenant-Governor considered that, as the cost of the institution was already too high, it was not advisable to enforce additional expenditure on the fund. The average number of women on the register during the year was 27, and there were 45 admissions among them against 33 in 1882.

The number of admissions of European soldiers into the Jellapahar lock hospital, Darjeeling, was only six out of an average strength of 221, or in the proportion of 27·14 per 1,000 against 111·11 in 1882. Four women were on the register at the beginning of the year; four others were added in the course of the year, and five were struck off, leaving only three on the roll on the 31st December. "These figures," it is remarked, "would seem to point "to the conclusion that unlicensed prostitution is prevalent, but it is difficult to reconcile "the inference with the unusual healthiness of the troops."

Madras.

In the Madras Presidency seven military lock hospitals were in operation, the same number as in the previous year. The average number of women on the register in 1883 was 667. In four stations the number was larger than in the previous year, and less in three. The total number of cases under treatment was 2,611 against 2,372 in 1882. Amongst the troops the ratio of admissions per 1,000 of average strength rose from 257 to 274. In the stations of Bangalore, St. Thomas's Mount, Secunderabad, and Wellington the results of 1883 show an increase in the amount of disease among the soldiers as compared with the previous year. An explanation of this, the Surgeon-General states, is found in the comparatively small number of women on the register in all the stations, and in the fact that the soldier does not confine his attentions to prostitutes under the surveillance of the police.

Bombay.

In the Bombay Presidency lock hospitals were maintained at the same 12 stations as in previous years. Amongst the troops the average rate of admissions into hospital per 1,000 of strength was 8·94 higher than it was in 1882, but the ratio was still less than it was during the immediately preceding five years. There was also considerably less disease in the stations where lock hospitals exist than in those where no such institutions were in force. "From recent evidence," the Surgeon-General, Her Majesty's Forces in the Bombay Command, states, "it would appear to be implied that the chief cause of venereal disease "lies in the illicit prostitution of unlicensed women in the neighbourhood of cantonments. "Increased vigilance of the police has been inculcated, but unless the soldiers themselves "choose to act discreetly in only cohabiting with licensed women, I fear that the meagre "powers with which the police are invested will not diminish these admissions for venereal "disease."

North-Western Provinces and Oudh.

The average number of registered prostitutes on the rolls of the 18 lock hospitals in the North-Western Provinces and Oudh fell from 1,087 in 1882 to 979 in 1883; but, as the average daily strength of the European garrison also fell from 13,291 to 11,471, the proportional strength of women was slightly greater, namely, 8·5 per cent. against 8·1. This, however, was much below the proportion which prevailed in 1879, when there were 12·5 women registered for every 100 soldiers in garrison. Excluding cases remaining in hospital at the opening of the year, 1,187 women were treated for venereal disease against 1,924 in 1882. This decline is the more satisfactory as it represented not merely an actual decrease corresponding with the diminished numbers of women on the registers but a very marked improvement in the proportion of cases to total strength, the percentage of women diseased in 1883 being 121·2 against 177 in 1882.

Notwithstanding the soldier's persistent preference for unregistered women, and the continued decrease in the number of unregistered women, the results of the working of the lock hospital system in the provinces were, on the whole, satisfactory. The number of soldiers admitted to hospital on account of venereal diseases was 2,704, or in the proportion of 235·7 per 1,000 against 263·7 in the previous year. The improvement was most conspicuous at Benares, Chakrata, Ranikhet, and Lucknow; while, on the other hand, the

returns were less favourable at Agra and Fyzabad, a result due partly to the movements of troops affording opportunities for intercourse with unregistered women, and partly to the want of a sufficient supply of registered women. It is reported that the venereal disease prevailing in the province is of a much milder type than that contracted by soldiers in England.

Central Provinces.

There are four lock hospitals in the Central Provinces, viz., at Kamptee, Saugor, Jubbulpore, and Pachmarhi. With the exception of Saugor the hospital returns show a decrease in the number of men admitted into hospital. At Pachmarhi the depôt troops numbered only 73, and among them there were but four admissions, or 54·78 per 1,000, against 10, or 97·08, in 1882; at Kamptee the admissions among the troops were in the proportion of 126 per 1,000 of average strength against 156; at Saugor the admission rate was 293 against 284 per 1,000, and at Jubbulpore there was a marked decrease, the admissions having fallen from 463 per 1,000 to 261. The average number of women on the registers was 157 against 185 in 1882, and the number of cases of disease and admissions into hospital among them was 318 against 400. Only at Pachmarhi were the admissions among prostitutes in excess of the number of the previous year.

British Burma.

The statistics of the six lock hospitals in British Burma for 1883 show that the average number of women on the register was 658 against 580 in 1882, and that amongst them there were 1,228 admissions to hospital on account of venereal diseases as compared with 1,083 in the previous year. Three out of the six hospitals, viz., Rangoon, Thayetmyo, and Toungoo, are regulated by rules made under the Cantonment Act, 1880, and are kept up chiefly for the benefit of the European garrison; while the Moulmein, Bassein, and Akyab hospitals are maintained for the benefit alleged to be derived from them by sailors visiting those ports. Of an average strength of 1,880 garrison troops the admissions for venereal diseases were in the proportion of 168·51 per 1,000. Compared with the previous year, Rangoon and Thayetmyo showed an improvement, but at Toungoo the admissions rose from 222·44 per 1,000 of average strength to 268·44. It is noticed in the Government Resolution on the Report for 1883 that "during the past five years, in the towns where lock hospitals "have been maintained, venereal diseases have increased in frequency among the European "troops, and apparently also among the general population. Whether the increase would "have been more rapid if the lock hospitals had not been maintained, or whether it would "have been less rapid if the rules had been more strictly enforced, it is impossible to say; "but it must be admitted that the statistics fail to show that any advantage has been derived "from the enforcement of the rules." Since the close of the year under notice the lock hospital at Moulmein has, at the wish of the Municipal Committee, been closed.

Lunatic Asylums.

Bengal.

At the five lunatic asylums in Bengal there were 1,081 patients under treatment during 1883, or 25 more than in 1882. In the course of the year 90 of the number were discharged as cured against 83 in the previous year, but the number of persons transferred to friends in an improved condition fell from 34 to 27; five were otherwise discharged, and 52 died, the smallest number on record, leaving 907 still under treatment at the end of the year against 849 in 1882. Out of the 232 cases admitted and re-admitted during the year the causes of insanity were unknown in 98; and of the cases in which causes were assigned, 108 were ascribed to physical and 26 to moral causes. In commenting on intoxication as a prevalent cause of insanity, the Surgeon-General makes the following remarks: "I have said before that "occurrences in the asylums show that the statements on this point are below—I might say "very much below—the truth, and that, on the other hand, resort to intoxication is sometimes "assigned as the cause of a derangement of which it is only an early result. There were in "all 76 admissions from ganja and bhang in 1883, and only 34 recoveries. If the cases were "rightly ascribed, the proportion was small, and again proves that, with increased admis-"sions, there was no increase of cases of mere temporary intoxication among them." The health of patients was very satisfactory in all the asylums, the admissions to hospital numbering only 235 against 394 in 1882 and 385 in 1881. Of the total cases under treatment, 4 were of cholera against 15 in 1882; fever cases fell from 108 to 46; dysentery from 82 to 34; and among the other principal diseases there was a decrease except in phthisis, from which the admissions rose from 23 to 26. The largest number of deaths was from phthisis, viz., 13; from cholera there were 2 deaths, from apoplexy 6, from diarrhœa 5, from dysentery 4, and from fevers 3. The low mortality from zymotic diseases is evidence of the efficiency of the sanitary arrangements in the asylums.

Of criminal lunatics there were 423 under treatment during the year against 384 in 1882, the primary admissions numbering 93 and re-admissions 12. The discharges as cured and tranfers rose from 41 to 50, and the deaths fell from 25 to 14; there were thus 359 still under treatment at the close of the year.

As regards the European asylum at Bhowanipore, 51 patients were under treatment, 24 of whom were admitted in 1883 against 20 in 1882. Of the total number, 3 were discharged as cured, 10 were deported to Europe under the Merchant Shipping Act or otherwise, 8 were transferred to the care of friends, and one died.

Madras. The statistics of the three lunatic asylums in the Madras Presidency for 1883–84 show that 652 patients of all classes were under treatment during that year against 617 in the previous year. The fresh admissions numbered 218, or two less than in 1882, of whom 36 were criminal lunatics against 43. At the close of the year there remained 493 patients under treatment (of whom 102 were of the criminal class), 98 having left the asylums as cured, 29 transferred to friends, 8 otherwise discharged, and 26 died, 2 being criminal lunatics. The returns exhibiting the causes of insanity in the patients in the various asylums show that the probable cause, in the majority of cases, is the abuse of narcotic drugs; but it is again reported that it is impossible in the greater number of cases to obtain any accurate account of the antecedent history of the patients. The general health of the inmates of the asylums was very favourable, and the mortality was only 50·5 per 1,000 of daily average strength.

Although small-pox and cholera were prevalent in Madras City during the year, they did not visit the Madras Asylum; in fact, no epidemic disease was present at any of the asylums.

It is reported that the majority of the patients are received in feeble health, and that they generally improve under the course of food obtained in the asylums.

Bombay. Although accommodation in the asylums of the Bombay Presidency was not so pressingly felt as in the previous year, it was still inadequate in four of the five asylums, consequently admissions had occasionally to be refused until vacancies occurred. The new asylum at Ratnagiri, which was still in course of construction, will relieve the pressure felt at the existing institutions; but as it appears to be making slow progress the attention of the Public Works Department has been invited to the matter, with a view to the speedy completion of the institution. The total number of patients under treatment during 1883 was 948 against 931 in 1882, of whom 812 were new admissions and 17 were re-admissions. In the course of the year 259 were discharged, 99 being sent away as cured, 160 transferred to the care of friends, and 79 died, or 27 in excess of the mortality of 1882. Of criminal lunatics there were 107 under treatment, being 5 more than in the previous year, and of these 15 were discharged, 10 died, and 82 remained at the close of the year. The alleged causes of insanity were known only among half the total 948 insanes; in 389 cases insanity was ascribed to physical causes, such as the use of *ganja*, spirits, and opium, and certain forms of disease, and in 85 cases insanity was attributed to moral causes, chiefly grief. The general health of the patients was fairly satisfactory, and there was no epidemic or extraordinary amount of sickness in any of the institutions; the patients suffered chiefly from debility, diarrhœa, epilepsy, dysentery, and fevers. Most of the deaths occurred amongst old and debilitated patients.

Punjab. At the two lunatic asylums in the Punjab (Lahore and Delhi) the total population in 1883, including 51 criminal lunatics, was 479, or 26 in excess of the previous year. Of these 143 were fresh admissions, 12 belonging to the criminal class. From both asylums 78 lunatics were discharged during the year, 31 as cured. The year was a remarkably healthy one, and there was no epidemic of any kind in either asylum. Fever formed the most frequent cause of admission to hospital. The deaths were 23 at Lahore and 8 at Delhi, equal to 80·9 and 95·9 per 1,000 of average strength respectively against 87·7 and 131·0 in the previous year; but at both asylums the average strength was greater than in 1882.

North-Western Provinces and Oudh. The number of lunatics under treatment in the four asylums of the North-Western Provinces and Oudh rose from 1,163 to 1,205, of whom 336 were fresh cases. At the end of the year the population of the asylums stood at 915, 218 having been discharged and 72 having died. Of the four asylums the mortality was again highest at Lucknow (143·5 per 1,000 of average strength), and lowest at Agra (47·2). "To some extent," it is reported, "this result was accidental, the Lucknow asylum having been particularly unfortunate in "having had a number of deaths from brain diseases, and in receiving a number of weak and "sickly patients; but there was reason for believing that the attention paid to the diet of the "insanes at Agra had had a good effect on the health returns of that asylum, and that

"especially the immunity of the inmates from bowel complaints was due to the care given to "the issue of vegetable acids continuously in the diet." At the other two asylums, Bareilly and Benares, the death-rates were 64·0 and 86·4 per 1,000 respectively.

Criminal lunatics appear to be steadily increasing. The number in 1883 being 196, as compared with 167 in 1882 and a 10 years' average of 142.

Central Provinces.

The aggregate number of patients under treatment at the two lunatic asylums in the Central Provinces during 1883 was 297, of whom 129 were confined in the asylum at Nagpur, and 168 in that at Jubbulpore. The proportion of cases cured was unusually small at Nagpur, being only 5 against 8 in the previous year, while at Jubbulpore the number discharged as cured was unusually large, 20 against 4 in 1882. "Mania," the Deputy Surgeon-General of the Provinces reports, "including both the acute and chronic forms, was "the type under which by far the largest number of patients admitted in 1883 was "suffering, as is, I think, the case in most Indian asylums; a large number of these cases "being really cases of poisoning by ganja or other preparation of Indian hemp." At Jubbulpore the lunatics appear to have enjoyed very good health, but at Nagpur fever and dysentery and diarrhœa were very prevalent. Altogether there were 10 deaths in the asylums, Nagpur contributing 4, the same number as in 1882, and Jubbulpore 6, against 4 in the previous year.

Berar.

At the Amraoti lunatic asylum in Berar 32 insanes were under treatment in 1883, of whom 9 were criminal lunatics. There were no fresh admissions during the year. Two patients were discharged cured, 1 was made over to his friends in an improved state, and 2 died, thus leaving 27 still under treatment at the close of the year. The health of the lunatics was exceptionally good, and, considering the general unhealthiness of the year, indicates, the Sanitary Commissioner observes, "careful management and attention to the "general comfort and requirements of these poor unfortunates." Both the deaths which occurred in the asylum were due to causes quite unconnected with locality, residence, or treatment, being the result of cancer. Acting on the suggestion of the Government of India, the Amraoti asylum has been closed, and the patients have been transferred to the asylum at Nagpur.

Assam.

Several sanitary improvements were effected during 1883 in the Tezpur lunatic asylum in Assam, the most important being the erection of two new barracks, with a view to obviate overcrowding. The year began with 61 patients under treatment, and before its close 32 others had been admitted, making a total of 93. Of these, 1 escaped, 9 were discharged cured, 2 were made over to friends, and 14 died, leaving 67 inmates at the end of the year. The medical history of the asylum for the year is an unfavourable one. An epidemic of cholera appeared in June and lasted three weeks, during which there were 20 cases of the disease and 9 deaths. This weighted the mortality very considerably, and gave rise to the heavy death-rate of 219·5 per 1,000 of average strength against 53·0 in 1882 and a five years' average of 91 per 1,000. Of the causes to which insanity was attributed in 18 ascertained cases, no less than 8 were attributed to ganja, while opium was credited with one patient only.

British Burma.

At the Rangoon lunatic asylum, 245 patients were under treatment during 1883, of whom 56 were fresh admissions. By the close of the year 43 had been discharged (19 as cured), and 12 had died, leaving 190 in the asylum. Of the 56 fresh cases the insanity of 12 was attributed to physical and of 16 to moral causes; while in 28 cases, or one half, no cause was assignable. The patients are reported to have enjoyed excellent health throughout the year, there having been no sickness of importance except what was presented by those who eventually died. The proportion of deaths to daily average strength was 63·5 per 1,000, a lower rate than in any year since 1877. More than 80 per cent. of the inmates were employed, chiefly in some kind of out-door work.

Medical Schools.

Bengal.

At the Calcutta Medical College the session of 1883–84 began with 126 students; 39 students of previous years rejoined the class, and there were 32 new admissions, making a total of 197 students against 228 in the previous year. At the end of the session four senior scholars and four paying students passed their final M.B. or L.M.S. examination; 15 hospital apprentices passed, and left for regimental duties, while 57 students ceased to attend. Thus, at the close of the session, the total strength of the college was 117 against 126. For

the first M.B. and L.M.S. examinations, 42 candidates went up, and 21 passed against 12 in 1882–83, eight being placed in the first division; 10 candidates out of 28 passed the final examination for the license in medicine and surgery against 11; and 9 candidates obtained the degree of bachelor of medicine against 7 in the previous year. Women were for the first time admitted to the class of the Medical College, and special women's scholarships of the value of Rs. 20 a month, tenable for five years in the college, were created, and will be awarded for the next 10 years, without restriction of numbers, to all female candidates who join the Medical College after passing the First Arts Examination.

Favourable results were also obtained at the four vernacular Medical Schools. The number of students at the Campbell Medical School rose from 170 to 190, and out of 47 candidates 37 passed the final examination for a diploma against 20 in the previous year.

At the Dacca Medical School there were 131 students, being an increase of 12 on the number of the previous year, and 33 candidates out of 40 passed the final examination against 16. The Temple Medical School at Bankipore had 192 students, of whom 11 were transfers from the abolished Medical School at Nagpur; out of 34 candidates 28, including the 11 from Nagpur, passed the final examination against 26 of the previous session. The number of students at the Cuttack Medical School was 35, or one less than in the previous year; 9 candidates appeared at the final examination, and all passed, against 12 in the previous year.

Madras.

The working of the Madras Medical College in 1883 again showed satisfactory results. The number of students, excluding the junior department, which was abolished, rose from 153 to 197. Of these 113, including three females, were in the senior department, of whom 19 presented themselves for the University examinations, when only two failed. The number of candidates is considered small when compared with the strength of the various classes of this department, and appears to be due mainly to the desire on the part of many of the students to obtain British qualifications, but the results of the examination were looked upon as very creditable to the class. In the second department there were 84 students, including 7 females. Twelve candidates, including one female, appeared for their final examination, and all passed. Of second year students, 26 went up for the primary examination, and all passed and acquitted themselves creditably, 4 getting places in the first class. Three females also appeared for examination and passed with credit. The Director of Public Instruction agreed with the Principal of the College that "the result of these examinations, characterised as it "is by absence of failure, must be very gratifying alike to teachers and to pupils." During the year, several students proceeded to Europe to continue their studies there.

It is gratifying to learn that His Highness the Maharajah of Travancore has generously given Rs. 6,000 for founding a scholarship tenable by women, and to be called the "Bharati "Lekshmi Scholarship." His Highness also gives a gold medal yearly to the best female student in midwifery.

Bombay.

In the Grant Medical College a class for female students has been opened in consequence of the demand which has arisen for female practitioners. At the commencement of the session of 1883–84 there were 12 members of this class, one of whom was an undergraduate of the University. "It is satisfactory to see," the Principal of the College observes, "that "at the inauguration of this new class some very promising candidates have presented "themselves, and I would here state that the conduct of all has been exemplary."

With regard to male students, the number on the rolls during the session was 338 or 5 less than in the previous year. Thirty-eight undergraduates competed for the L.M.S. degree of the University, and 28 passed,—5 in the first and 23 in the second class. At the first L.M.S. examination there were 93 candidates, 43 of whom were successful, 7 passing in the first and 36 in the second division. Three assistant surgeons presented themselves for examination for the higher grade, and all were found qualified for promotion. From the hospital apprentice class 13 fully-instructed apprentices passed out for duty.

The medical schools at Poona, Ahmedabad, and Hyderabad, were progressing favourably, and like the Grant College have been thrown open to women. There was a decrease in the number of students at Poona and Ahmedabad as compared with the previous year, but in the Hyderabad School the number of pupils rose from 30 to 38. The results of the examinations were on the whole satisfactory. Fifteen senior students from Ahmedabad and 16 from Poona passed their final examinations. The Hyderabad School having been open for only two years was unable to send up any men for final examination.

VII.—SANITATION.

Bengal.

On the whole, the progress made in 1883 in improving the sanitary condition of the town of Calcutta does not compare favourably with the previous year. Amongst the improvements effected was an increase in the filtered water-supply from a daily average of 7,868,062 to 7,975,960 gallons, and during the hot weather months, March to June, to a daily average of nearly 8½ million gallons. It has long been recognised that the supply was incommensurate with the essential requirements of the town, and it is satisfactory to learn that Calcutta was within measurable distance of an adequate provision of this first necessity; though, unfortunately, there appeared to be little probability of the new extensions being in working order by the hot season of 1885. There was also an increase in the daily average supply of unfiltered water from 1,988,175 gallons to 2,035,808. The drainage system of the town was nearing completion, though the amount of work executed did not come up to that of previous years. Only 46,672 feet of sewers were constructed, and of these 18,796 feet were converted into paths varying from 3 to 10 feet, and 3,713 feet were converted into roads 15 to 20 feet wide. During the year much attention was given by the Commissioners to the reclamation of bustees. Eighteen projects for the structural improvement of bustees were under consideration, but only one was completed; in four the work was well advanced, and the remaining 13 had not advanced beyond the preliminary stage. Out of the grant of 15,000*l.* made to meet the cost of sanitary and structural improvements in the bustees, little more than a third was expended.

For some time past the Calcutta sanitary question has been a subject of controversy between the Government of Bengal and the Municipal Commissioners; and in 1884 the Lieutenant-Governor of Bengal appointed a Commission to investigate the matter. The Commission, while fully admitting that much had been done of late years to improve the sanitary condition of the city, pointed out the great need for more active measures; at the same time they made several important recommendations with regard to future work. Both the Governor-General of India and the Lieutenant-Governor of Bengal concur in the views of the Commission, and trust that the Municipality will spare neither trouble nor expense to complete the sanitary reforms so much needed. A Memorandum on this subject by the Army Sanitary Commission will be found in the Appendix, p. 233.

At the port of Calcutta cleanliness was fairly maintained throughout the year at all points of the river bank on the Calcutta side; the khal, however, which passes through the premises of the ex-king of Oudh, discharged into the river the drainage and, at times, much filth, which it brings down from the interior; sewage was again being discharged into the river from the flushing inlet at the Port Commissioners' jetties. The attention of the authorities was called to these matters, and thus led to their rectification. The Calcutta foreshore was being further improved by the erection of additional public latrines. The condition of the Howrah foreshore was reported to be satisfactory. An embankment was in course of construction on this side of the river, which, it is believed, will assist in improving the conservancy of the bank. Attention was called to the want of latrine accommodation for those who will use this embankment.

Of a total income of 332,876*l.* the municipalities of Bengal expended 114,793*l.* or nearly 34½ per cent. on sanitary works against 31 per cent. in 1882, besides 60,616*l.* on the construction, maintenance, and repair of roads. The expenditure under water-supply amounted to 16,045*l.* against 3,109*l.* in the previous year; but of this amount 11,052*l.* were spent on the water-works of Burdwan, in which considerable progress was made. Improvements were also made in the water-supply for the towns of Berhampore, Dacca, English Bazar, and Kurseong. The question of the extension of the Calcutta water-supply system to the suburbs engaged the careful attention of the Government during the year, and it was expected that material progress with the works would soon be made. A scheme for providing a supply of filtered water for all the riparian municipalities on the right bank of the Hooghly, between Serampore and Howrah, was also proposed; but the difficulties in the way of carrying it into effect have been found more considerable than was anticipated. The obstacles, however, were not considered insuperable, and it was hoped that before long some feasible solution would be discovered. Meanwhile, the proposal was under the consideration of Government.

In several towns drainage schemes were inaugurated, and in most cases taken in hand. Progress was made with the Cuttack drainage scheme which was commenced in 1879, and the town is believed to be now fairly well drained. Further improvements were effected in the fever-stricken district of Nuddea, and in the Sonthal Pergunnahs a survey of the great swamp to the south of Rajmehal, which is a source of much disease, was made with a view to improve its drainage.

Among the miscellaneous sanitary operations of the year was the extension of sanitary clauses of several Bengal Acts to a number of towns and villages; and new Acts were passed

for the sanitation of Indian merchant shipping, the regulation of Native passenger ships, and for revising the law relating to municipalities in Bengal. During the year a number of villages was inspected by the officers of the vaccination staff, and their reports revealed a sad neglect of sanitation by the people. One officer states that in each village, hat, and bazar which he visited he delivered lengthy and earnest addresses on sanitary matters, pointed out defects, and made suitable and practical remedial suggestions. "To remedy "defects," he says, "such as I have noticed, sanitary legislation of some sort to meet the "requirements of rural dwellings is called for, if the physical welfare of the people is to be "espoused. My observations teach me that the people, rich and poor, educated and "uneducated, alike, cannot, or will not, actively bestir themselves in bringing about sanitary "reforms." Speaking of a village in Dacca, which was visited by a severe outbreak of cholera, he says: "The wonder to my mind is that the health of the people is as good as it is, and "that they look as well as they do, seeing their almost indescribably filthy surroundings "and unclean habits." In discussing this subject the Army Sanitary Commission remark: "The obvious consequence of this state of matters is that the Government should "step in and deal with these sanitary problems. Something has been done for the towns, "and, as we have seen, some improvements are being carried out there, but as we have often "urged, the town populations are a mere fraction of the whole population of Bengal, "and it is hence in the villages that the causes of epidemics have to be encountered "and overcome."

Madras.

Good progress was made with the drainage scheme for Black Town during 1883. The pump and engine house at Rayapuram, the outfall channel and masonry weir, and one of the main sewers of the new drainage system were practically completed. In connection with the general scheme 11¼ miles of surface drains of various sizes were constructed; 314 new house drains were constructed by the owners themselves, and 21 by the municipality. The total amount expended on drainage during the year was 16,435*l.*, which added to 7,892*l.* spent in 1882 gives a total expenditure of 24,327*l.* out of an available sum of 40,000*l.* raised by loan for the purpose.

Further progress was made in the useful work of diverting drains from the Cooum and the canal. The diversion from the river of the contents of the large sewer near Government House was nearing completion at the end of the year, and the engines and pumps were in course of erection.

The extension of the water-supply throughout the town which was commenced in the previous year was completed at a total cost of about 26,000*l.* Pipes of various sizes extending over 28 miles were fixed, besides 170 valves, 463 hydrants, 178 fountains, and 27 silt traps which were considerably over and above the number contemplated in the original extension scheme. The water-supply from the Red Hills was maintained throughout the year, excepting for two days in September in five divisions (4th to 8th), when the supply was shut off to enable a 14" scour-pipe to be fixed at the junction of Purasavakum High Road and Brick Kiln Road. Proposals were made to secure the conservancy of the shores of the Red Hills Lake, and powers were inserted for this purpose in the new Municipal Act.

In the municipalities of Madras Presidency, exclusive of the City, the sanitary allotments for 1883–84 aggregated 57,000*l.* or 33·2 per cent. of income against 49,000*l.* or 31 per cent. in the previous year. Of this sum, however, only 69 per cent. was expended during the nine months ending December 1883. No sanitary work of any magnitude was carried out during the year; the operations consisted mainly in repairing and cleansing of tanks and wells, latrines, drains, &c.; in the construction of latrines, drains, and dust-bins; in the sinking of wells, and in some other minor works. Similar work was executed in the local funds circles, where the amount set apart for sanitary purposes was nearly 40,000*l.* or 28·8 per cent. of income. Compared with the previous year this shows a falling off of 3,700*l.*, but with very few exceptions the allotments were considered generally sufficient. Of the sanctioned allotment 45 per cent. remained unexpended at the close of December. The attention of the authorities has been called to the custom of leaving so large a proportion to be expended at the end of the year, "the result being," the Government observe, "that large "sums not unusually lapse, or that the works are hurried through, or badly done." It is noticed that in the previous year (1882–83), 9·7 per cent. of the whole allotment of the municipalities remained unutilised, and 20 per cent. of that of the local funds. "It is to "be hoped," the Sanitary Commissioner remarks, "that recent orders of Government and of "the Board of Revenue on the subject will in future have the desired effect towards the "complete utilisation of funds placed at the disposal of the local authorities for sanitation, "and that as skilled agency has now been provided by the appointment of district "medical and sanitary officers for indicating and devising measures by which the funds

" of the local boards can be most advantageously expended, conservancy and improvement " of village sites and water-supply—the greatest sanitary needs of a locality—will receive " due attention, and the expenditure on their account will be strictly watched."

Bombay.

Considerable progress was made during 1883 in measures for the improvement of the Bombay water-supply. The construction of the new reservoirs on Bhandarwada and Malabar hills was completed, and the catch-water channels at Vehar and Tulsi, for increasing the gathering-ground, were being energetically pushed on. The laying of the new water main to Vehar was expected to occupy two seasons, but it was hoped that the portion that was expected to be ready by the end of the first season (which would be connected with the existing main at Coorla) would confer an appreciable benefit in the hot season. Owing to the increased height of the dams of the Tulsi lake, the draw-off was at a higher level than in previous years. Wastage of water from leakage, to the extent of nearly 400,000 gallons a day, was discovered and rectified, and with a view to its prevention, the Deacon metre system, which has been found to answer well in provincial cities in England, was to be introduced as soon as possible. The drainage of the city was receiving careful attention. Much was done to relieve the low-lying parts of the city from floods by the construction of intercepting drains; but the Municipal Commissioner points out that an intolerable nuisance is caused by the carriage in them of sewage, which must continue until all sinks, gullies, and cesspools are connected with new sewers. "Whether " the whole of the sewage," the Health Officer of the City remarks, "will ultimately be " carried by the sewers, or whether the more highly scientific and sanitary mode of conveying " by them only the sullage and subsoil water, and of returning the night-soil to the land " to be adopted, it is a matter for sincere congratulation that—it is to be hoped—at no very " distant date the larger number of the 1,800 cesspools which are to be found scattered " over Bombay will be done away with, and the disease-producing subsoil water, in a " measure, removed. When this has been accomplished, and a sufficient supply of whole- " some drinking-water provided, two of the chief causes of disease in this city will have " been swept away." Good work was done during the year in road-making. Several new ones were made; but the greatest improvement in this direction was the extension of Charni Road to Grant Road, by which a new thoroughfare which was much needed has been created.

The Sanitary Commissioner of Bombay, Deputy Surgeon-General Hewlett, testifies to the many improvements in the city of Bombay which have taken place during the last 10 years. He says: "Perhaps no greater has been effected than the raising of the ground level in " Khetvadi by filling it in. On all sides I see places which I remember to have been sources " of disease gradually being improved, but the town is still an Augean stable, and requires " an immense deal to be done to it before it can be considered as at all approaching a " satisfactory condition; one of the greatest wants from a sanitary point of view, after an " additional water-supply and the completion of the sewage scheme is, in my opinion, a " Building Act. This want, ever since the municipality has been established, now 19 years " ago, has been repeatedly brought to notice, but the question has always been shelved, as " it would be unpopular among the property-owning classes. Still, I think, that in the " interests of public health it should be urged again and again." This matter was receiving the attention of the Government. The Governor in Council was of opinion that such further provisions as might be considered necessary, could most appropriately be embodied in the amended Municipal Act, and with this view the Sanitary Commissioner has been directed to state in detail the amendments and additions which he considered necessary.

No special sanitary work of any magnitude was accomplished in the other municipalities of the Bombay Presidency during the year, though much was done in improving the water-supply and drainage of towns, and minor matters. Out of a total income of about 271,000*l.*, nearly 115,000*l.* were expended on conservancy; while in the local fund circles about 27,000*l.* were spent in the construction of sanitary works. The Kas waterworks for supplying the town of Satara were completed, as were also the new waterworks at Chiplun. The scheme for bringing the Mahi water to Karachi was drawing towards completion; pipes were being laid on to all public places, gardens, and private houses. There was little expenditure on drainage works during the year. At Ahmednagar branch drains were constructed and connected with the two existing drains. At Nasik five new drains were constructed and connected with the existing drains. At Sukkur the new drainage scheme for new Sukkur and Ghariliabad was sanctioned, and a commencement made with the works. In the Surat Municipality measures were being devised for a thorough drainage of the city by means of underground drains; but these, it appears, cannot be carried out until a sufficient supply of water for flushing is obtained.

During his tour of inspection the Sanitary Commissioner (Deputy Surgeon-General Hewlett) was surprised at the energy shown by some of the municipalities in matters of sanitary

reform. During a visit to Ahmedabad he had the opportunity of perusing a memorandum written by the Chairman of that Municipality for the benefit of his colleagues, "and the "thorough knowledge of the subject displayed in it," he says, "as well as the extremely "practical and sound advice given in it struck me so forcibly that I submitted it to Govern- "ment, with a request that I might be permitted to have it printed as an appendix to my "annual report, as in my opinion it is a most remarkable document to have been written by "a native gentleman, and it will show the Secretary of State the great good that is being "effected in this country by the publication of the memoranda of the Army Sanitary "Commission. It will also, I hope, give a stimulus to Commissioners in other municipalities "to follow so excellent an example." Mr. Hewlett concludes his report with the remark "that although the year has been one in which there has been an unusually heavy death-rate, "yet the prospects of real sanitary reform being introduced are most encouraging, as Govern- "ment has, in many important points, indicated its determination to initiate measures which "cannot fail to produce a lasting improvement on the public health of this Presidency."

Punjab.

The income of the municipalities in the Punjab during 1883 amounted to 410,047*l.*, of which 121,977*l.* were spent on sanitary works. The expenditure on this head is reported to be steadily increasing in many towns, which would seem to indicate that municipal committees are taking more interest in matters of this kind than formerly. The Lieutenant-Governor hopes that district officers will, with the assistance of district boards, effect similar results in the matter of village sanitation. Of the sanitary works completed or undertaken during the year, the following were among the most important. In Lahore the new reservoir for storing drinking water was approaching completion. The water supplied from the system was said to be excellent, it was universally used, and is reported to have had a beneficial effect on the health of the people. Considerable improvements were effected in the drainage system of Lahore city, and a project was in contemplation for draining the civil station. In Amritsar the plans for the scheme for a water-supply were well advanced; good progress was made with the extra-mural drainage project for the city; but very little was done towards the intra-mural scheme; an income of about 2,500*l.* was derived from the sale of manure, and the sanitation of the town had much improved. At Simla progress was made with the Sanjauli reservoir in connexion with the waterworks, and it has since been completed; and a project was under consideration for replacing by oval-shaped cast-iron drains the wooden V-shaped drains used for carrying off the drainage of the bazaar into Combermere ravine. Plans and levels for the drainage of Sialkot city have also been prepared. A covered drinking-water tank was completed at Deoband in Derajat division, and similar tanks have been made on the Murree and Abbottabad road in Rawal Pindi. At Georgegarh in Rohtak, a large masonry tank has been built to meet the deficient supply of water. The Peshawar Municipality brought to completion the large project known as the city canal, which has been for some time under construction. The work, which has cost a considerable sum of money, consists of a main channel of flowing water from the Bara river, pure enough for all ordinary purposes, with a masonry channel at lower level on either side, by which the drainage of the city is carried off.

North-Western Provinces and Oudh.

In the North-Western Provinces and Oudh no special sanitary works of importance were undertaken during the year, but many improvements were effected in roads, drainage, sources of water-supply, conservancy, &c. "Wherever the means of improvement are available," the Sanitary Commissioner states in his Report for 1883, "there some proportion of the available "income is expended for the improvement of the habited site or its precincts. These improve- "ments of every kind and character have been reported to me for information." With reference to this statement the Army Sanitary Commission remark: "A comparison of the "death-rates for five years preceding 1883, would apparently lead us to the conclusion that "life was being saved under the existing sanitary administration and progress. Thus, the "town death-rate in 1883 from all causes was 35·32 per 1,000, while the previous five years' "ratio was 40·88 per 1,000, showing a reduction of 4½ per 1,000."

Central Provinces.

The only sanitary works of any importance carried out in the Central Provinces during 1883 were the completion of the waterworks at Jubbulpore and Hinganghat. In most of the districts good work was done in providing better water by new wells, in cleansing and repairing tanks, and in constructing roadside drains, &c. In reviewing the Sanitary Commissioner's Report for 1881 the Army Sanitary Commission called attention to several disease causes in the villages of these provinces as revealed by the reports of inspection officers, with the remark that "a mere statement of them ought to carry the remedies with it." To this the local authorities have replied that the difficulties to be encountered are very great. "In "fact," they say, "there is no more difficult problem than to get the villagers to recognise "the insanitary and unwholesome condition of their surroundings, to revolutionize their daily

" habits and practices, and to supply the very considerable sums of money which would be " needed to remove even any one of the causes to which disease is attributable." With reference to this statement the Government of India say: " There is no doubt much truth in " these remarks, but it is equally true that if district officers really interest themselves in " the matter, a great deal can be done by their influence and judicious guidance to improve " the surface drainage of villages, to set apart and preserve in good order tanks or wells for " providing pure water to the villages, to keep clean the compounds and surroundings of " houses, and to provide accommodation for keeping cattle as well as for latrine purposes at " a distance from human habitations. It is of the highest importance that the improvement " of the conditions under which the people live should be regarded as most intimately connected " with their happiness and prosperity, and that it should not be set aside as a thing which is " practically impossible." To this " wise judgment " the Army Sanitary Commission have nothing to add. " It involves," they say, " no outlay for great sanitary works. The people " themselves could do nearly the whole of it. Cleansing and keeping clean, with a little " spade labour now and then to drain the surface, and very ordinary care in protecting water " sources would soon tell on the sanitary state of villages, if the local officers would include " these matters as amongst those on which their influence might be brought to bear."

Berar.

In Berar the works for supplying the town of Amraoti with water by means of pipes from the Kalapani tank, at an estimated cost of 30,000*l.*, was in progress, and have since been completed. The Wadali tank, intended for both cattle and drinking purposes at the station of Amraoti, was completed, and the Hergowan tank for the use of cattle was in course of construction. In Ellichpur district tanks were being constructed for providing water for both cattle and drinking purposes. Tanks and wells were also built in the Akola and Buldana districts. In the six municipalities of the province 16,943*l.* were allotted for sanitary purposes, of which 15,688*l.* were spent; but of this amount only 2,393*l.* were expended on village sanitation. The results of the inspections of villages and towns by the Sanitary Commissioner revealed a state of things sadly calling for improvement. So long as such filthy habits and customs exist, the Army Sanitary Commission observe, " the main disease " causes will continue to act just as they do at present. That the municipal towns require " thorough improvement is shown by the disease statistics, and a comparison with the jail " death-rates for corresponding years points clearly to the direction in which improvement " should be carried out." The Resident has again called the attention of all district officers " to the necessity of carrying out the rules laid down in the village Sanitary Code, and of " preventing as far as possible the accumulation of manure and filth inside the boundaries " instead of at suitable places on the outskirts of each village."

Assam.

On sanitary improvements in Assam a sum of 8,348*l.* was expended in 1883, which is a considerable increase on 5,657*l.*, the amount spent in the previous year. The new water supply for Shillong was completed at a cost of 1,500*l.*, and has provided the station, it is stated, with as pure and abundant a water service as any station in India. The native population has received it with great favour, and new pipes were still being laid down to supply private taps to the houses of fresh applicants. The scheme for supplying Gauhati with pure water was also in progress. The drainage works in Goalpara after long delay have been completed, " and the local opinion strongly holds that they have caused a great " improvement in the sanitary condition of this once water-logged town." In no other municipality was any special work carried out, but nearly all of the municipalities spent larger sums than in the previous year in street-sweeping, cleaning of drains, and construction of roads and culverts. " The first and most pressing want of all towns in Assam," the Chief Commissioner notices, " is a pure supply of water: it ranks before drainage and before " latrines." Instructions were to be issued to all district engineers to draw out plans for providing water to all the towns on the same system as has been devised for Gauhati.

British Burma.

No sanitary works of any great importance were undertaken in British Burma during 1883, except a comprehensive scheme of water-supply and drainage for the town of Prome, the works connected with which were making rapid progress. Much attention has been devoted to the sanitary improvement of Prome of late years, and now that drainage and water-supply have been provided, steps were being taken to improve the conservancy system. In Rangoon the waterworks were all but completed, and water was laid on to all the principal streets. The drainage of the town was also receiving attention, and some preliminary steps towards its execution were taken. In almost all the principal towns many minor improvements were effected in cleansing and repairing wells, constructing public latrines and drains, filling cess-pits, &c., while everywhere great attention was given to conservancy arrangements. On such improvements a sum of 19,996*l.* was expended by the 15 towns of the province.

No progress, however, appears to have been made in improving the sanitary condition of villages. "In this direction," the Chief Commissioner says in his Resolution on the Sanitary Commissioner's Report, "rapid progress is hardly to be expected. The elements "of sanitation are now taught in all Government schools, and it may be hoped that the "people will gradually learn to effect for themselves many sanitary improvements which "Government officers are powerless to effect for them."

Military.

Bengal. The total expenditure on military works in the Bengal Command during 1883–84 was 673,532*l.* against 531,306*l.* in the previous year. The works included new barracks at several stations, new hospitals, and buildings for the general requirements of the Commissariat department. Military roads were under construction, the most important of which was the Bolan high-level road from the terminus of the railway at the mouth of the pass along the Bolan valley and across the great dasht or plain to Quetta, the entire length being 86 miles. Amongst general cantonment works were the completion of the Peshawar water-supply scheme, the extension of the Umballa water-supply, the provision of water to Pishin, and the commencement of the supply of water to Chakrata. Drainage works at Naini Tal have been carried out, and further progress made with the drainage of Quetta, and also with its cantonment roads.

Madras. The Surgeon-General of Her Majesty's Forces in Madras Presidency reports that during 1883 the sanitation of all buildings connected with the troops as well as their surroundings was carefully attended to, and special precautions taken as epidemic disease was prevalent among the civil population. The supply of water has generally been sufficient and the quality good, and every attention has been paid to the protection of the sources of supply. The improvement of the water-supply at Bangalore was receiving the earnest attention of Government; while efforts were being made by the municipality to improve the sanitation of the Ulsoor bazaar, the proximity of which to the infantry barracks at Bangalore caused some anxiety during the prevalence of cholera. Generally speaking, the drainage of the stations was satisfactory. The Madras Municipality were doing their best to put a stop to the long-standing nuisance in Fort St. George caused by the discharge of fœtid sewage from the main drain into the sea just outside the fortifications. At the station of Secunderabad there appears to be a want of proper drainage from the town. At present, it is reported, the whole of the sewage runs by the back of the staff lines into the Husain Saugor tank which was very detrimental to the health of the neighbourhood. A scheme, however, for improving the drainage of the town was under the consideration of the Resident.

Bombay. The expenditure on military sanitary works in the Bombay Presidency during 1883 was 17,473*l.* against 11,904*l.* in the previous year. Of this sum about 9,580*l.* were expended on Native lines for Jacobabad. At Ahmedabad, 3,458*l.* were spent on sanitary improvements, all but 32*l.* being devoted to the construction of a hospital for British troops. At Nasirabad 2,134*l.* were expended, nearly a quarter of the amount on the construction of new open drains; while at 19 other stations various minor works were undertaken, including the preservation and watering of trees planted in connexion with sanitary improvements to Ghorpuri barracks at Poona.

W. T. Ronson.

India Office,
November 1885.

ABSTRACT

OF

SANITARY AND OTHER REPORTS

FOR

1883.

ABSTRACT OF REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1883.

(DR. J. M. CUNINGHAM.)

European Troops.

During 1882 the health statistics of the army of India are as a whole most favourable. During 1883 they were more favourable than they had been in 1882. From the following table it will be observed that the admission, daily sick, and death-rates for 1883 are lower than those of any of the previous years there given, and that all, except the daily average sick-rate, are lower than the average of the ten-year period 1870–79 :— Sickness and mortality in 1883.

Year.	Strength.	Ratio per 1,000 of Strength.				
		Admissions.	Daily sick.	Deaths.	Invaliding.	Total loss.
1870–79	577,416	1,475	60	19·34	43	62
1878	56,475	1,651	68	21·46	45	66
1879*	49,582	1,927	76	24·28	49†	73†
1880*	51,796	1,789	74	24·85	26†	51†
1881†	58,728	1,605	70	16·86	38	55
1882	57,269	1,445	65	12·07	33‡	45
1883	55,525	1,336	63	10·88	33	44

* Excluding troops serving in Afghanistan. † Including troops in Afghanistan.
‡ Calculated on the strength obtained from Annual Returns.

The admission-rate, 1,336 per 1,000, is indeed the third lowest on record since 1870, when the statistics for the army of India were first compiled as a whole; in 1873 the admission-rate equalled 1,328, and in 1877 it was at the minimum of 1,257. Notwithstanding the low admission-rate of the year, the daily average sick-rate (63) was higher than the ten-year average of 1870–79, and higher than that of every year from 1870 to 1877 inclusive. The death-rate for the year 1883 was 10·88, the lowest on record since 1870, when it equalled 21·11. This result was most gratifying, falling short, as it does, of the average death-rate for the period 1870–79 by 8·46 per 1,000. The loss to the army, due to invaliding, was 33 per 1,000, identical with that of the preceding year, but 10 per 1,000 less than the average loss on this account during the period 1870–79. The total loss to the army from death and invaliding was 44 per 1,000, or less than the average annual loss of 1870–79 by 18 per 1,000.

The vital statistics of the army of the Bengal Presidency, taken by themselves, are very satisfactory. The average strength was 34,079, against 35,164 in 1882. The admission-rate was 1,463, a smaller ratio than that of any single year since 1878, and considerably smaller than the average ratios of the ten-year periods 1860–69 (1,755) and 1870–79 (1,522). Of the past 23 years since 1860 better results were recorded in 7, the most favourable having been 1,251 in 1877. The daily average sick ratio is still high, namely 66 per 1,000. It exceeds the average of the period 1870–79 (61) by 5 per 1,000, but is less than that of 1860–69 (67) by one only. The most satisfactory feature in the statistics of this portion of the army of India is the greatly diminished mortality. This equalled 11·21, and is the lowest ratio on record. The nearest approach to it was in 1877, when it equalled 11·64. The death-rate of 1883 was thus 9·79 per 1,000 less than the average death-rate for 1870–79 (21·00), and 18·77 per 1,000 less than the average of 1860–69 (29·98). The mortality from cholera was also exceptionally low; it was 0·94 per 1,000. The average death-rate from this disease during the last two decennial periods was 4·18 (1870–79) and 9·24 (1860–69). The cholera mortality of the year under review, however, is not the lowest on record, for the rate in 1870 was only 0·68, and in 1871, 0·71, in 1873, 0·90, in 1874, 0·21, and in 1877, 0·44. The loss by invaliding was 31, or 10 per 1,000 less than the average

loss during 1870–79. The total loss to the Bengal Army from death and invaliding was 42 against 48 in 1882, and 62 the average total loss during 1870–79.

In the Madras army also the results are, on the whole, very favourable. Out of an average strength of 10,498, which was somewhat less than in 1882, the admission-rate was 1,013, the lowest on record since 1870; the next lowest (1,053) having been in the preceding year 1882. The daily average sick ratio (59), however, did not show a corresponding decrease; it was slightly higher than that of 1882 (57), and practically the same as the average for 1870–79 (60). The death-rate was 10·19; a result almost identical with that of 1880 (10·18), the lowest on record. Deducting the mortality due to cholera, which was 0·95, the ratio was 9·24, or the same as that of 1881. The loss by invaliding was higher than it has been of late years, and equalled 33 per 1,000. The average of 1870–79 was 49. The total loss to the army from death and invaliding was 43, or 9 per 1,000 greater than it had been in 1882; a result which is accounted for exactly by the increase of invaliding.

The average strength of the Bombay army, (10,948) was a little less than it had been in 1882. The admission-rate was 1,249, the lowest on record. The daily average sick (57), however, did not fall in a corresponding degree, and remained the same as the average for the period 1870–79. The total mortality from all causes (10·50) was in excess by a fraction of that of the preceding year (10·37). The excess was due to cholera mortality; for deducting the deaths due to this disease the mortality from all other causes (9·68) was less in 1883 than it had been in 1882 (9·74), and is the lowest on record.

The force in Southern Afghanistan is included in the Bombay statistics referred to in the preceding paragraph, but it is desirable also to show the results among these troops separately. Out of an average of 1,034, which was slightly in excess of that of the preceding year (929), the admission-rate was considerably below what it had been during the two previous years; but both the daily sick and death-rates were higher. The daily sick-rate was 78, which is considerably above the average rate for the army of India during the ten-year period 1870–79, when it stood at 60. The death-rate from all causes was 15·47, as compared with 9·69 in 1882, 51·55 in 1881, 49·00 in 1880, and 59·48 in 1879. There was no mortality from cholera, as indeed there had been none in former years excepting in 1879, when a proportion of 32·69 was due to this cause. There were in all 16 deaths against 9 in 1882. Of the 16, five were due to enteric fever and four to respiratory diseases.

Malarial fevers as usual gave rise to the largest number of admissions in the Bengal Presidency, or an equivalent of 486 per 1,000. This ratio, however, is a great improvement upon those of the majority of previous years. The average admission-rate under this head for the ten-year period 1860–69 was 633·0 per 1,000, whilst for the succeeding ten-year period 1870–79 it was 607·3. The ratio for 1883 shows, therefore, a considerable reduction over the averages of both periods, and compares even more favourably with the ratio of 1882, which was 660 per 1,000. A similar, though not so marked, diminution occurred in the admissions from fevers in the Madras and Bombay Presidencies, both as compared with the ratios of the preceding year and with the average results of the ten-year period 1870–79. In the Madras Presidency the ratio was 128 per 1,000 against 171 in 1882, and in the Bombay Presidency, 436 against 558. The average for the ten-year period 1870–79 in Madras was 266, whilst in Bombay it was 660.

TOTAL OF THE NINE	1,216		800		1,023
TOTAL FROM ALL CAUSES	1,463		1,013		1,249

The admission-rate from venereal diseases was highest in the Madras Army (289), and lowest in the Bombay Army (218). In Bengal it was higher (281) than it had been in

1882 (271); in Madras it was practically the same (289 against 288 in 1882), and in Bombay it was somewhat less (218 against 224). In all three Presidencies the admission-rates were in excess of the average rates for the ten-year period 1870–79, the excess being 72 per 1,000 in the case of Bengal, 91 in Madras, and 27 in Bombay. Respiratory diseases, as usual, gave rise to the highest admission-rate in Bengal, 88 per 1,000. It was 41 in Madras and 73 in Bombay. These ratios for Bengal and Bombay are higher than the average ratios for 1870–79, which were 84 and 64, respectively; that for Madras for the same ten-year period having been only 57. Diarrhœa was more prevalent in the Bengal and Madras Presidencies than in the Bombay Presidency. In all Presidencies the ratios under this head are less than the averages for 1870–79. Dysentery and hepatitis were, as usual, much more prevalent in Madras than in Bengal and Bombay. Scurvy does not appear in the statistics among the diseases which caused admissions into hospital; but the Surgeon-General, Her Majesty's Forces, Bengal Presidency, in remarking upon the health of the men during 1883, writes that "scurvy sometimes in a pronounced form, but most commonly in a "mild one, has been prevalent amongst men of many corps and at different stations; those "serving at hill stations have proportionately suffered most in this respect, and no doubt the "scorbutic taint in particular men has commonly, if not always, been a sequel in malarial "fever illness."

Enteric fever again heads the list of the chief causes of death in all three Presidencies. The highest ratio under this head was recorded in the Madras Presidency (2·86), and the lowest in Bombay (1·55), the Bengal ratio being intermediate (2·52). During 1882 the number of deaths ascribed to this cause in Madras rose suddenly, and during 1883 the ratio has for the first time exceeded the ratios of the Bengal and Bombay Presidencies. It was almost exactly double the average rate of the ten-year period 1870–79. Further details regarding enteric fever will be found in a subsequent paragraph.

Deaths from the Chief Diseases and from All causes in the Three Presidencies per 1,000 of strength.

* Excluding troops in Afghanistan and on the march. † Include deaths from intermittent fever.

Hepatitis as usual caused the largest proportion of deaths in the Madras Presidency (1·72 per 1,000). The death-rate for the year, however, was only about one-half the average death-rate of the period 1870–79. In the other two Presidencies also the mortality from this cause was less than the ten-year average. It was in Bengal 1·06 and in Bombay 0·82. The death-rates from cholera were remarkably low in every Presidency; as already shown, they were for Madras 0·95, Bengal 0·94, and Bombay 0·82. The ratio for Bengal is particularly low; the average mortality during 1870–79 having been 4·18. Apoplexy caused the largest number of deaths in Bengal (1·32 per 1,000). In Madras the death-rate from this disease was particularly low, 0·38 per 1,000 against 1·42 the average of 1870–79. In Bombay it was 1·10, a ratio higher than that of the preceding year, but less than the ten-year average. There has been a reduction of death-rate from dysentery in the Bengal and Madras Presidencies, both when compared with the ratios of the preceding year and with the ten-year averages; in the Bombay Presidency the death-rate from this disease (0·55) was higher than it was in 1882 (0·18), but still lower than the ten-year average (0·98). The mortality from remittent and continued fevers was greatest in the Bombay Presidency (0·55) and least in Madras (0·28); in Bengal it was 0·41. All these ratios are less than the ten-year averages; but the most striking reduction occurred in the Bengal Presidency.

Excluding convalescent depôts, where troops are located only for a portion of the year, the statistics of the army of the Bengal Presidency have been divided into six groups. Of these four show a higher admission-rate than the average for the Presidency as a whole, whilst one was nearly equal to it, namely, Bengal Proper, and one was considerably below it. The highest admission-rates occurred in the Punjab (1,601), and Meerut with Rohilcund groups (1,528), and the lowest in Bengal Proper (1,011).

Statement showing the Admission and Death-rates in the several groups of Stations of the Bengal Presidency during the ten-year periods 1860–69, 1870–79, *and during* 1880, 1881, 1882, *and* 1883.

Period.	Ratio per 1,000 of strength.

* Excluding troops in Afghanistan and on the march. † Including troops in Afghanistan and on the march.

The admission-rates in the Gangetic Provinces with Oudh (1,474) and Meerut with Rohilcund (1,528) were greater than the average rates of the period 1870–79, though less than the average rates of the preceding ten-year period 1860–69; but the admission-rate in Hill Stations for 1883, namely, 1,454, exceeded both ten-year periods considerably. Indeed, the admission-rate for 1883 in the Hill Stations is the highest on record since 1870, with the single exception of the year 1879, when it was 1,560 per 1,000. Fevers were most prevalent in the Punjab, Rohilcund with Meerut; dysentery and diarrhœa in Hill Stations and Gangetic Provinces; respiratory diseases in Hill Stations, Punjab, and Gangetic Provinces; and venereal diseases in Bengal Proper. "The augmentation of sickness," says the Surgeon-General, Her Majesty's Forces, "in Rohilcund was not consequent on unhealthy conditions "within the district, but was due to the arrival of troops whose health had been greatly "deteriorated by immediately previous residence in the Punjab."

The highest mortality was recorded in the Gangetic Provinces (17·04), and Agra and Central India (14·27); but these ratios are nevertheless favourable when compared with many former years. The average death-rates in the Gangetic Provinces were 28·59 and 20·06 in the ten-year periods 1860–69 and 1870–79, and in the Agra and Central India group the ten-year averages were 38·48 (1860–69) and 18·41 (1870–79). After these two groups in order of high mortality come Meerut and Rohilcund (10·56), Punjab (9·47), Bengal (9·10), and Hill Stations (6·33). The chief causes of mortality in the Gangetic Provinces were cholera (3·92) and enteric fever (3·17). In Agra and Central India 4·26 per 1,000 of the death-rate was due to enteric fever, whilst 1·25 per 1,000 were due to each of the following—cholera, apoplexy, and hepatitis. The highest mortality from cholera was recorded as usual in the Gangetic Provinces (3·92); this was somewhat less than the average death-rate of the period 1870–79, namely, 4·24. The mortality from enteric fever varied from 1·07 in Bengal to 4·26 in Agra and Central India; and it is noteworthy that the death-rates from "other fevers" varied inversely from 1·07 in Bengal to 0·25 in Agra and Central India. In every single group, with the exception of the Punjab, the mortality from enteric fever for 1883 was greater than the ten-year average, and that from other fevers almost correspondingly reduced. Apoplexy caused the highest death-rate in the Punjab (1·93), in the Gangetic Provinces (1·66), and in the Bengal groups (1·60); it was lowest in the Hill Stations (0·25), and in Rohilcund and Meerut (0·80). Dysentery gave rise to the largest mortality in Bengal (1·07), and to the least in Punjab (0·18). Respiratory diseases gave rise to the highest rates in Agra and Central India (1·00), and Punjab (0·88), and least in Rohilcund and Meerut (0·26).

In individual stations the highest admission-rate was recorded in Attock (3,390), but excluding this and other small stations with an average strength of less than 200 men, five stations recorded over 2,000 admissions per 1,000, ranging from 3,032 per 1,000 in Amritsar to 2,563 in Peshawar. In all these five stations fevers and venereal diseases caused the largest proportion of admissions; in Delhi, Mean Meer, and Peshawar, respiratory diseases

also prevailed largely. Of 92 stations, 39 recorded higher admission-rates than the average admission-rate for the whole army of India (1,336).

The following stations, with an average strength exceeding 200, recorded the highest mortality:—Benares 39·89, Gwalior Fort 34·97, Dinapore 26·82, Delhi 24·94, Shahjahanpore 23·81, and Kamptee 23·33. In Benares, with an average strength of 376 men, 15 deaths occurred from various diseases. In Gwalior (average strength 429) of a total of 15 deaths, eight were due to enteric fever and five to cholera. In Dinapore (932 strength) there were 25 deaths, seven of which were due to enteric fever and seven to cholera. In Delhi (401) there were 18 deaths from various causes, and in Shahjahanpore (210) five deaths. In Kamptee, with an average strength of 600, there were 14 deaths, five of these due to enteric fever, three to cholera, two to hepatitis, and the remaining to various diseases. In 38 of the 92 stations the total mortality exceeded the average of the army of India. In Chakrata, Pachmarhi, Landour, Deesa, Khandalla, and Taragarh, which were occupied for only a portion of the year, there were no deaths; and the same remark applies to Purandhar, Baroda, Malliapoorum, and Calicutt, which were occupied during the entire year by a small body of men.

There were 9,035 men located in the hill stations of Bengal Presidency, or 26·51 per cent. of the average strength of the army. In 1882 the percentage was 27·44 and in 1881 25·3. The general health of men in the hills was not so good as it had been during the preceding year, for whilst in 1882 the admission-rate was 975 per 1,000, during 1883 it was 1,454 per 1,000. This admission-rate is unusually high, the average ratio for 1870–79 having been 1,044. The sickness represented by these figures cannot, however, have been of a severe nature, for the total mortality fell from 8·65 in 1882 to 6·33. This death-rate is the lowest on record since 1870, the nearest approach to it being in 1877, when it was 6·49.

In the Rajputana-Malwa group, which is the first belonging to the Bombay Command, the statistics are very favourable. The admission-rate was 1502 as compared with an average admission-rate of 1,614 during 1870–79, and the death-rate 8·32 as compared with an average of 17·41 during the same ten-year period. The admission-rate of the year, though on the whole favourable, was higher than it was during the years 1873–77, when it ranged from 1,244 to 1,492. The total death-rate of the year 1883 was by far the most favourable on record since 1870, and was less than one-half the average of the ten-year period. The chief components of this total death-rate, which includes 0·43 due to cholera, were 1·07 from enteric fever, 0·85 apoplexy, 0·64 dysentery, and 0·85 hepatitis. The highest admission-rates were recorded in Indore (2,026) and Baroda (2,006); both are small stations; the former with an average strength of 115, and the latter of 168. The largest station, Mhow (1,239), had an admission-rate of 1,822, and a total death-rate of 8·07. The highest death-rates were recorded in Indore (17·39), and Karachi with Ghizree (16·34).

The strength of the European Army in the Deccan and Nagpur group was considerably smaller than in 1882,—6,994 against 7,685. The admission-rate was 1,001 (the lowest on record since 1870) against 1,029 in 1882, and an average of 1,383 during the ten-year period 1870–79. The mortality, however, (10·72), was higher than it was in 1882 (7·94). This last ratio was exceptionally low, the average mortality for the ten-year period having been 14·14. The chief causes of admission were venereal diseases, which caused 265 per 1,000 of the total admission-rate, and intermittent fevers, which caused 191 per 1,000; whilst the chief causes of mortality were enteric fever (2·72), cholera (1·72), "other fevers," hepatitis and respiratory diseases, each causing 0·71 per 1,000. Of the 11 stations comprised in this group, five recorded higher admission-rates than 1,000 per 1,000. Poona and Secunderabad, with average strengths of 1,087 and 2,281, respectively, are the largest stations. The admission-rate in Poona was 973, and in Secunderabad 811. No less than 327 of the total admission-rate at Secunderabad were due to venereal diseases. The highest death-rates were recorded in Asirgarh (24·00), Kamptee (23·33), Kolhapur (22·99), and Satara (20·98). With the exception of Kamptee, where an average strength of 600 men was quartered, the stations mentioned are small, and a few deaths gave rise to the large ratios. In Kamptee, of a total of 14 deaths, five were due to enteric fever and three to cholera. The death-rates in Secunderabad and Poona were 8·33 and 7·36, respectively. Of the Secunderabad mortality, 2·19 were due to cholera; there was no cholera mortality in Poona. The mortality in Poona exceeded that of the previous year, which had been only 2·85; an unusually low rate. The average death-rate in this station for 1870–79 was 11·91, whilst the average ratio for Secunderabad during the same period was 19·95.

The average strength of the force located in Southern India was 4,661. The admission-rate (1,126) was somewhat greater than it had been in 1882 (1,119), but below the average for 1870–79 (1,235). The total death-rate was 8·58, also somewhat higher than that of the two preceding years (7·74 in 1881 and 8·30 in 1882), but it compares favourably with the

average death-rate of the past decade (13·70). Of the total admission-rate, 339 per 1,000 were due to venereal diseases. The next highest admission-rates were for wounds and accidents (128) and intermittent fevers (89). The chief causes of mortality were enteric fever (3·44) and hepatitis 1·72. In this group seven stations are included, the largest being Bangalore with an average strength of 1,821, Bellary with an average of 985, and Cannanore with 688. Four of the seven recorded higher admission-rates than 1,000, the highest being 1,356 in Bangalore. The highest death-rates were recorded in Bangalore (11·53), Madras (7·79), and Cannanore (7·27). The death-rate at Bangalore was almost identical with the average death-rate in that station during the past decade (11·81), whilst the ratios of Madras and Cannanore were considerably below the averages, which were 12·75 and 14·90, respectively. At Bellary the death-rate was 7·11 against an average death-rate of 9·87.

The average strength in the British Burma group was 2,001. The admission-rate was 980 as compared with 1,047 in 1882, and 1,092, the average of the last decade. The total mortality was 10·00; this compares very favourably with the average mortality of the ten-year period, which was 17·32. During 1883 there were no deaths from cholera. The chief cause of mortality was hepatitis (2·50). Next to it come dysentery and injuries, each contributing 1·00 per 1,000 to the total. Only four stations are included in this group, the largest being Rangoon with an average strength of 733. The admission-rate was greatest in this station, 1,304, which was contributed to most largely by venereal diseases (266), fevers (151), dysentery (106), and hepatitis (106). The highest death-rate, 14·29, occurred in Port Blair, a small station with an average strength of 140 men; two deaths gave rise to the ratio. In Rangoon the death-rate was 10·91; of the eight deaths in this station, four were due to hepatitis.

The statistics of an average force of 811 men of the Madras and Bombay armies in the hills of these Presidencies are, on the whole, favourable. The admission-rate was 1,059 against an average rate of 1,594 during 1870–79, and the death-rate from all causes 8·63 against an average of 15·16. Both the admission and death-rates were smaller than in 1882.

Cholera. In the report for 1882 attention was drawn to the remarkable abeyance of cholera during that year; the history of 1883 is even more striking in this respect. Throughout the army of India only 82 cases of cholera were treated, or a ratio of 1·5 per 1,000, and of these 51 or 0·92 per 1,000 died. During the preceding year 98 cases (1·7 per 1,000) were admitted and 61 (1·07) died. The mortality among those seized was 62·20 per cent. against 62·24 in 1882. These favourable results for the army, as a whole, have been mainly due to the small number of cases which occurred in the Bengal Presidency, for the admissions and deaths in the other two Presidencies were somewhat more numerous than they had been in 1882. In the Bengal Presidency only 48 cases occurred with 32 deaths against 73 cases and 45 deaths in 1882. These results, though very favourable, are, however, by no means the most favourable on record, for since 1860 fewer cases, both absolutely and proportionally, were admitted in the three years, 1871, 1874, and 1877. The admission-rate per 1,000 was in the Bengal Presidency 1·4 against 5·9 in 1870–79 and 14·7 in 1860–69. The death-rate per 1,000 was 0·94 against 4·18 during 1870–79 and 9·24 during 1860–69, and the percentage of deaths among those seized was 66·67 against an average of 62·72 during 1860–69 and of 70·26 during 1870–79. Whilst these average ten-year ratios show that both the prevalence and mortality per 1,000 have greatly diminished of late, the percentage of deaths amongst those attacked has risen. Eleven individual years between 1860 to 1879 show a smaller percentage of deaths among those attacked than the percentage of 1883. In the Madras Army 19 cases occurred with 10 deaths, yielding admission and death ratios of 1·8 and 0·95 per 1,000, respectively. The average admission and death-rates during 1870–79 were 2·9 and 1·68. The reduction in the ratios of the year under review, as compared with this ten-year period, was therefore not so great as in Bengal. The percentage of mortality among those treated was 52·63 against an average percentage of 58·49 during 1870–79. In the Bombay Army 15 cases with nine deaths were recorded, or 1·4 per 1,000 of admissions and 0·82 of deaths. These results are not so favourable as those of the three preceding years, but are better than the average ratios of the ten-year period, which gave an admission-rate of 2·1, and a death-rate of 1·53. Of those treated in this Presidency, 60·0 per cent. died against an average percentage of 73·27 during the last decade.

With regard to the distribution of the disease in the several geographical groups of the Bengal Presidency, it may be noted that the largest number of cases and deaths occurred in the Gangetic Provinces with Oudh. The admission-rate in these Provinces was 5·9 per 1,000 and the death-rate 3·92. In three of the six groups, including the Hill Stations, there was an entire absence of the disease, whilst in Bengal Proper only one case occurred. A similar but greater preponderance of cases in the Gangetic Provinces was observed in 1882.

Small-pox. Small-pox was more than ordinarily prevalent in the army of India. There were in all 105 cases as compared with 44 in 1882, and nine deaths against four. The admission-rate

was 1·9 per 1,000 of strength as compared with an average of 0·7 during 1870–79, and a death-rate of 0·16 against an average death-rate of 0·10 during the same period. The percentage of deaths amongst those attacked was low (8·57) against an average of 14·71 during 1870–79.

The increased prevalence of the disease in the army of India was mainly due to its increased prevalence in Bengal. There were 86 cases admitted, the largest number recorded in any year since 1870, and exceeded only in the years 1860, 1861, 1864, 1865, and 1869. The admission-rate per 1,000 of strength in the Bengal Presidency was 2·5, compared with an average admission-rate of 2·2 during 1860–69 and 0·8 per 1,000 during 1870–79. All but five of the cases occurred between January and May, the driest part of the year, and the year itself was one of the driest on record for many years. The death-rate per 1,000 of strength (0·21) was nearly double that of the period 1870–79, but was below the average death-rate of the preceding ten-year period 1860–69. Although the prevalence of the disease in the army of the Bengal Presidency was considerably greater than usual, it is satisfactory to be able to note that the mortality (7) amongst those attacked was only 8·14 per cent. against an average of 15·3 during 1870–79 and 15·57 during 1860–69. Of the 86 cases which occurred in the Bengal Army, 47 occurred in the Gangetic Provinces with Oudh, and 39 in the Agra and Central India groups. Of the seven deaths, four took place in Lucknow, and one in each of the following stations:—Shahjahanpur, Agra, and Jubbulpore. In the Madras Presidency the admission-rate was 0·9 against 0·5 in 1870–79, and the death-rate 0·10 against 0·09. Here, too, the disease was more than usually prevalent, and the mortality amongst those attacked 11·11 per cent. greater than it was in Bengal. In the Bombay Presidency the admission-rate was 0·9 against the decennial average of 0·6, and the death-rate 0·09 against 0·05. The mortality amongst the attacked was 10·0 per cent.

Fevers.

There was a great diminution in the prevalence of intermittent fever during the year. For the army of India, as a whole, the admission-rate was 359 and the death-rate 0·05. During the preceding year (1882) these ratios were 494 and 0·07, respectively, whilst the average admission and death-rates for 1870–79 were 389 and 0·14. The admission-rate in Bengal, which has risen of late years, fell during 1883 to 425 per 1,000, a ratio identical with the average admission-rate of the past decade. The death-rate was 0·03, the same as that of the preceding year, and considerably below the average rate during 1870–79 (0·17). In the Madras Army these fevers were least prevalent. Here during 1883 the admission-rate was only 99 per 1,000 against 146 in 1882 and 140, the average rate during 1870–79. There were no fatal cases. In Bombay the admission-rate (405) was less than one-half what it was in 1880, and more than 100 per 1,000 less than it was during 1882. The death-rate, continued to be high, namely 0·18 against 0·16, the average death-rate during 1870–79. It was, however, smaller than that recorded in 1882. The prevalence of intermittent fever was greatest in the Bengal Presidency, and of the several groups in this Presidency the admission-rates were highest in the following:—Punjab 546 per 1,000 Meerut and Rohilcund 539, and Agra with Central India 507. In the Gangetic Provinces the admission-rate was 256, and in Bengal Proper 134.

The admission-rate from remittent and continued fevers for the army of India equalled 49 per 1,000—a lower rate than that of the preceding year (53), and a great improvement upon the average of 1870–79, which was 162. The total death-rate was 0·41 against 0·61 in 1882 and 0·65 in 1881. In all the three Presidencies the admission-rates during 1883 were considerably less than the average rates of the past ten-year period. Compared with the preceding year the admission-rate in Bengal (62 per 1,000) was practically the same: in Madras (30) it was a little higher; in Bombay (31) it was considerably less.

Enteric fever.

The tendency to return an increasing number of continued fever cases as enteric fever year by year has been frequently noted in former reports. The results of the year under review show that that tendency still continued. In the army of India 429 cases of fever were recorded as cases of enteric fever against 357 in 1882. These numbers yield ratios of 7·7 per 1,000 of admissions in 1883 and 6·2 per 1,000 for 1882. During 1883, 133 died of the disease, or 2·40 per 1,000 against 2·55 in 1882. Notwithstanding the greater frequency of the disease during 1883 as compared with 1882, the mortality was therefore less. From 1870 to 1877 the admission-rate fluctuated between 2·8 and 4·6, and during this time the mortality per cent. of those attacked varied from 50·88 to 39·49, or a mean of 43·73. In 1878 the admission-rate rose to 8·5 per 1,000, or almost double the highest rate recorded during 1870 to 1877, and continued high during 1879 (8·0) and 1880 (7·9); the death-rate per cent. of those attacked remained much the same as it was during the period 1870–77, for it varied from 43·01 to 46·17, or a mean of 44·72. During 1881 the admission-rate again fell suddenly to 5·6; but the percentage of deaths somewhat increased (47·26).

During 1883 the admission-rate again rose to a high ratio (7·7), but the death percentage was only 31·00, the lowest on record since 1870. In the following table the admission and death-rates from enteric fever and other fevers in the three Presidencies are contrasted :—

Period.	Bengal.						Madras.						Bombay.					
	Admissions per 1,000.			Deaths per 1,000.			Admissions per 1,000.			Deaths per 1,000.			Admissions per 1,000.			Deaths per 1,000.		
	Enteric Fever.	Other Fevers.	Total.	Enteric Fever.	Other Fevers.	Total.	Enteric Fever.	Other Fevers.	Total.	Enteric Fever.	Other Fevers.	Total.	Enteric Fever.	Other Fevers.	Total.	Enteric Fever.	Other Fevers.	Total.
1870-79*	5·3	607·3	612·6	2·22	1·74	3·96	5·8	280·5	270·4	1·62	0·93	2·04	3·1	659·9	663·0	1·78	1·14	2·92

* Including troops on active service and on the march. † Excluding troops in Afghanistan.

In 1880 the Bombay Presidency recorded the highest admission-rate (9·5) : during 1881 and 1882 the Bengal Presidency took the first place in this respect with admission-rates of 6·3 und 7·3, respectively; but during 1883 the Madras Presidency records the highest admission-rate (8·6), or more than twice the ratio it recorded in 1882 (4·0). But that the severity of the disease in this Presidency was much less, is indicated by the fact that whilst in 1882, 52·27 per cent. of those attacked died, in 1883 this ratio fell to 33·33 per cent. The next highest admission-rate occurred in Bengal (8·1), and the smallest in Bombay.

The absence of any definite relationship between the admission-rates for enteric fever and for other fevers, as may be seen from the above table, was noted in the report for 1882 : the addition of another year's figures serves to strengthen this conclusion.

The largest number of cases was admitted during July to October (214 cases), and the smallest during November, December, January and February (70). During the hot and dry months, March, April, May, and June, 145 cases were admitted.

The highest mortality per 1,000 of strength was recorded in Madras, 2·86, the next in Bengal, 2·52, and the least in Bombay, 1·55. The high mortality in Madras is unusual, as may be seen in the following table in which the death-rates from this disease and from other fevers are given for a series of years :—

Presidencies.	Fevers.	1871.	1872.	1873.	1874.	1875.	1876.	1877.	1878.	1879.	1880.	1881.*	1882.	1883.

* Excluding troops in Afghanistan.

The mortality in Madras for 1883 is the highest on record since 1870, the next highest ratio having been recorded in 1872, viz., 2·34. The average death-rate in Madras during 1870–79 was 1·42, but it is made up of variations from 0·63 to 2·34. The mortality in Bengal for 1883 (2·52) is but little greater than the average ratio for 1870–79, viz., 2·28. Here, also, this average ratio is made up of extremes from a minimum of 1·53 (in 1873) to 4·69 (in 1878). The Bombay death-rate is fractionally less than the ten-year average, which is 1·75.

In the report for 1882 it was remarked that although enteric fever had been added as a new form of fever to the nomenclature of Indian diseases, no increase in the mortality of fevers as a whole had resulted, and that whilst the mortality from enteric fever had, of late years gradually increased, so the mortality from other fevers had almost correspondingly decreased. The experience of the year 1883 is to a like effect. In the following table it will be seen that the total mortality from all fevers, including enteric fever during 1883, was

less than the average total mortality of 1870–79 in all Presidencies, with the exception of Madras, in which it was slightly greater. The table also illustrates forcibly the proposition that together with an increasing mortality from enteric fever there has been a reduction in the mortality from other fevers:—

Mortality from Enteric Fever and other Fevers.

	During 1870-79.			During 1883.		
	Enteric fever.	Other fevers.	Total of both.	Enteric fever.	Other fevers.	Total of both.
Army of India	2·03	1·42	3·45	2·40	0·46	2·86
„ Bengal	2·28	1·74	4·02	2·52	0·44	2·96
„ Madras	1·42	0·62	2·04	2·86	0·28	3·14
„ Bombay	1·75	1·14	2·89	1·55	0·73	2·28

The largest number of cases in any one station occurred in Lucknow, 44 cases were admitted, and of these eight died or 18 per cent. In Bangalore 40 cases were admitted, and 11 proved fatal, or 27 per cent; 26 cases occurred in Secunderabad with seven deaths (27 per cent.); 25 in Karachi with only two deaths (8 per cent.); 22 in Subathu with two deaths (9 per cent.); 18 in Meean Meer with two deaths (11 per cent.); 15 in Morar with seven deaths (46 per cent.); 13 in Dinapore with seven deaths (54 per cent.); 13 in Ferozepore with five deaths (38 per cent.). In Sitapur, which during the preceding year returned the largest number of admissions (45), there were only 10 cases with two deaths (20 per cent.)

The relationship between enteric fever and age has been so fully discussed in former reports that it is unnecessary to repeat in detail the facts there brought forward. It will suffice to reproduce the tables given in former reports with the figures and ratios for 1883 added:—

Composition of the Army of India according to age, 1871–83.

Year.	Under 25.	25 to 29.	30 and upwards.	
1871—75	38 per cent.	27 per cent.	35 per cent.	= 100
1876	33 „	33 „	34 „	= 100
1877	33 „	35 „	32 „	= 100
1878	35 „	36 „	29 „	= 100
1879	39 „	33 „	28 „	= 100
1880	41 „	34 „	25 „	= 100
1881	43 „	35 „	22 „	= 100
1882	41 „	36 „	23 „	= 100
1883	41 „	35 „	24 „	= 100

The proportions of men at the different ages are almost identical with those of the preceding year.

Statement showing the Death Ratios of the European Army from Enteric Fever at different ages, together with Ratios of Liability to it for 1877–83.

Year.	Mortality from Enteric Fever and Ratio of Liability to it at Different Ages.					
	Under 25.		25 to 29.		30 to 34.	
	Deaths per 1,000.	Percentage of liability.	Deaths per 1,000.	Percentage of liability.	Deaths per 1,000.	Percentage of liability.
1877	2·45	44·2	1·55	27·9	0·99	17·8
1878	6·04	53·0	3·55	31·1	1·04	9·1
1879	6·17	54·1	2·73	23·9	1·78	15·6
1880	6·25	56·26	3·15	28·35	1·09	9·81
1881	4·56	59·84	1·57	20·60	0·79	10·37
1882	4·32	56·18	1·55	20·16	0·78	10·14
1883	4·34	66·36	1·50	22·94	0·70	10·70

The figures for 1883 show that both the mortality from enteric fever and the ratio of liability to it are by far the greatest among young soldiers under 25 years of age. The mortality among these young soldiers was 4·34, whilst for men between 25 and 29 and from 30 upwards it was only 1·50 and 0·70, respectively. The percentage of liability among young soldiers under 25 years was 66·36, the highest on record since 1877, and 10·18 per cent. higher than it was in 1882. The percentage of liability rapidly falls with increasing age. For men between 25 and 29 it was 22·94, and for men above that only 10·70.

The relationship between enteric fever and length of Indian service has also been frequently discussed in former reports. As shown in the following tables, the results of 1883 fully bear out former conclusions that the disease attacks soldiers of short residence in India in much greater proportion than others, and further show that the greater the proportion of young acclimatized men in the army of short residence in India, the greater is the liability of the army to loss from this disease :—

Statement showing the Proportion of Men who have served in India, two, five, and seven years from 1871–83.

Period.	Percentage of Men to Total Strength who have served in India.			Period.	Percentage of Men to Total Strength who have served in India.		
	Two Years and under.	Five Years and under.	Seven Years and under.		Two Years and under.	Five Years and under.	Seven Years and under.
1871	36·2	64·6	78·9	1878	28·9	59·8	73·0
1872	33·7	66·7	80·9	1879	32·1	60·9	72·6
1873	31·7	65·5	79·6	1880	33·4	65·4	77·2
1874	25·9	64·3	79·8	1881	38·9	70·4	81·1
1875	26·1	60·1	81·0	1882	33·1	71·9	82·9
1876	25·5	57·6	75·1	1883	32·3	74·7	85·5
1877	25·2	56·2	72·6				

From these figures it appears that in 1883 out of every 100 men only 14·5 had served longer than seven years.

Statement showing the Death Ratios of the European Army from Enteric Fever at different periods of residence in India, together with Ratios of Liability to it for 1877–83.

1883	4·98	70·34	1·55	21·89	0·55	7·77

In Bengal Proper three cases of enteric fever occurred, one in January, one in June, and one in October. In the Gangetic Provinces with Oudh there were two periods of prevalence, one culminating in May (12 cases), the other in September (15 cases). The culmination in May was rapidly reached from 3 cases in March, but that of September more gradually, for the cases rose from 0 in June through 4 in July and 9 in August to 15 in September. In the Gangetic Provinces the disease was least prevalent in March, June, and November. There was also a slight rise during December and January. In Agra and Central India there was one period only of increase, in August, when 13 cases were admitted; the cases fell in September to 8, and in October to 1. In the Punjab there was a gradual increase in the number of cases, from 8 in March and 11 in April to 16 in May; thereafter the disease

subsided gradually, until only 1 case occurred in August. Another smaller rise began in September, culminating in November (9 cases). During December, January, and February, there were very few cases :—

The reports by medical officers of cases occurring under their treatment, show, as usual, how indefinite are the symptoms which are often presented by cases of this kind. In numerous instances the patients were admitted primarily as suffering from ordinary remittent fever and even febricula. Thus one medical officer writes :—"Many of the cases were "admitted for febricula, and after a few days changed to enteric fever." Another writing of his cases says :—"The eruption characteristic of enteric fever is in this country more often "absent than present; diarrhœa invariably absent until the disease is very advanced and "ulceration has set in; pulmonary complications severe, congestion of the lungs sets in early; "and so marked was this in one case, that one of the most accurate observers and painstaking "medical officers I ever met, diagnosed an admission as a case of pneumonia, one that died "of a most virulent form of enteric fever in seven days." Again, in Morar, 15 cases were admitted against three in the preceding year, and the medical officer, after discussing fully the difficulties attending the diagnosis of a case of enteric fever from one of an ordinary continued or remittent type, expresses his belief that during the preceding year cases of enteric fever were included among cases of remittent and continued fevers. The extreme variations in the duration of cases, both of those which recovered and those which ended fatally, noted in the report for 1882, is again observable in the reports of 1883. In Umballa the average duration of the cases which terminated favourably was 43 days; but one case ended fatally on the second day. At Morar, a case was recorded, which ended fatally 36 hours after admission; the patient, it is stated, was "a man whose constitution had been "evidently debased by frequent ague attacks and drinking; and although the intestines showed "no positive ulcers, the glands and Peyers patches were inflamed, and their surroundings

" tumefied, giving reason to the belief, that had he not died at so early a stage, they would in " a very few hours have presented the usual ulcers." As the symptoms of this fever are so indefinite, it is not surprising to find an extreme amount of variation in the death-rate per cent. of those attacked. In other words, whilst some medical officers regard only those cases as enteric fever, which present the gravest symptoms, others include cases of much simpler character. Omitting those hospitals in which only a very few cases were recorded, and confining attention to those in which the largest numbers occurred, it will be found that the mortality per cent. of those treated varied from 8·00 at Karachi, where 25 cases were treated, to 27·50 at Bangalore, where 40 cases were treated. At Gwalior Fortress, where, however, only 12 cases were treated, 8 died, yielding a percentage of 66·6. At Subathu, of 22 cases treated, 2 died (9·09 per cent.), and of 1 of these it is noted, that " the temperature " chart varies greatly from the usual outlines of enteric fever," while in the report of the *post mortem* appearances found, it is stated, the " Peyers patches were intact." With regard to the etiology of the disease, no positive results of any value were arrived at. Most medical officers note the improbability or impossibility of fæcal contamination of the food or water of the soldiers. Similarly, no fault is found with the sanitary condition of the barracks. In a few cases, fanciful probable causes of the disease are stated. For example, one medical officer writes :—" No cause was assigned at the time, but afterwards, as the tank water used " for the tatties frequently emitted a most offensive and putrid odour, I came to the conclusion " that this in drying upon the tatties was most probably the cause." Another writes, that the milk is open to suspicion, as dirt from the udders of cows got into the milk while they were milked, and he proceeds :—" If filth be regarded as a source of typhoid fever, this is a " very possible source of danger." Several cases which occurred in Meean Meer were attributed to the use of " pop and milk brought round by natives." At another place the outbreak is attributed to a breach in an aqueduct. The medical officer presumes that this aqueduct " was utilised for washing their clothes, and bathing in," and a senior officer criticising this, says :—" This opinion is confirmed by the fact of the absence of enteric fever " after the breach in the aqueduct was closed." The influence of youth and short residence " in India, on the other hand, is abundantly evident. It will suffice here to quote in illustration, the facts in this respect at Lucknow, where 44 cases occurred in all. Of these, no less than 35 occurred among men of the Derbyshire regiment, which arrived in India from Egypt on 24th November 1882, and which was principally composed of very young soldiers. Of the 44 cases which occured in Lucknow, 33 occurred in men between 20 and 24 years of age, and nine in men from 25 to 29: 33 had been less than a year in India, and five over one year but less than two years. With regard to infection as a cause of the disease, most medical officers were unable to adduce any evidence. One medical officer writes :—" The " idea of infection cannot be held, as five of the cases occurred in different months and could " have had no relation to each other; of the remaining four, though they all occurred in the " same month, namely, November, two were stationed in opposite ends of cantonments, and " of the other two, one had just come down from the hills, the other had recently arrived in " the station from England." At Jubbulpore three cases occurred, all fatal, and all from different localities: they " could not be traced to any common cause in water, milk, or " individual locality." At Lucknow, where as already stated, so many cases occurred, the medical officer records that " even in the barracks occupied by the regiment which supplied " most of the cases, there was no marked prevalence in any one building or locality." Lastly, at Cherat, of the seven cases which occurred " three belonged to the same company, " but came from different tents; other three cases from the same regiment came from different " companies and from localities widely apart." It has already been noted above that 40 cases occurred at Bangalore. The Surgeon-General, Her Majesty's Forces, Madras, in his report on enteric fever amongst British troops in the Madras Command for 1883, quotes the medical officer's views as to the probable causes of enteric fever there as follows :—" No insanitary " defects could be discovered within the barracks. The water-supply (mixed water from the " Ulsoor tank and dhobies' wells as usual) was impure from contamination by excrement and " filth of every description. There is not only the immediate danger from the pollution of " the water-supply tank, but as a portion only of the filth washed into it becomes oxidised " and innocuous, the remainder is deposited on the bed of the tank ready to give forth in the " dry season, when the water is low and the bed of the tank (125 acres in extent) is exposed " to the sun, the noxious vapour which in conjunction with the use of the water predisposes " to, if they do not directly cause, this fatal form of fever." And the Surgeon-General remarks :—" The conditions referred to in these extracts are, in my opinion, sufficient to " account for the prevalence of enteric fever at Bangalore." The unsatisfactory nature of the water-supply at Bangalore has often been noticed. The subject was again under the consideration of the Madras Government, who had received an exhaustive report from an officer specially deputed to investigate the whole question.

Throughout the army of India there was a slight diminution in the prevalence of dysentery. The admission-rate was 27 per 1,000 as compared with 29 in 1882, and 40 the average rate of the past decade. Diarrhœa, as estimated by the admission-rate, was exactly the same as it had been in 1882; in both years the admission-rate being 46. This ratio is, however, considerably less than the average ratio for 1870–79, 63 per 1,000. Together with the great reduction in these diseases as compared with the past decade, it is noteworthy that the severity of the disease was also less. The percentage of deaths amongst those treated for dysentery was 1·40, whilst the average percentage was 3·65; for diarrhœa it was in 1883, 0·68 against an average of 0·19. In both, therefore, the percentages of 1883 were much less than the average ratios. The total death-rate per 1,000 of strength was 0·38 in the case of dysentery and 0·04 in diarrhœa. Both ratios are smaller than those for the preceding year, and the average ratios of 1870–79. Dysentery, as usual, was most prevalent in Madras and least prevalent in Bombay, the admission-rates being 49 in Madras, 23 in Bengal, and 18 in Bombay. Bowel complaints.

The highest death-rate per 1,000 of strength occurred in Bombay, 0·55, where the admission-rate was least. The ratio considerably exceeds that of the preceding year, which was 0·18. The smallest death-rate occurred in Madras, 0·28, where the admission-rate was greatest. This death-rate is an improvement upon that of the preceding year (0·36), and is the lowest on record since 1870. In the Bengal Army the death-rate, 0·35, is also the lowest on record (since 1868). Diarrhœa was most prevalent in Bengal (admission-rate 49). In Madras the admission-rate was 45 and in Bombay 39. The variations are not so great as in the case of dysentery; all ratios are considerably below the average ratios of 1870–79. The mortality from diarrhœa was trifling; it was 0·06 in the Bengal Army, and there were no deaths from the disease in the other two Presidencies. For the whole army of India the mortality was one-third the average mortality during 1870–79.

In comparison with 1882 there was a somewhat increased prevalence of, and mortality from, apoplexy. The admission-rate for the whole army of India equalled 3 per 1,000 against 2, and the death-rate was 1·10 against 0·85 in 1882. The increased admission-rate was due to an increase in the Bengal Army, as the admission-rate in the Madras Army was less than it had been in 1882, and that of the Bombay Army was the same. The increased total mortality also was due to an increase in the Bengal and Bombay Armies. The admission-rate in the Bengal Army, 4 per 1,000, is however identical with the average admission-rate for the last two decades, and the death-rate, 1·32, was below the averages of those periods. In the Madras Army both the admission and death-rates (1 and 0·38 per 1,000 respectively) were considerably less than the average rates. In the Bombay Army the admission-rate (2 per 1,000) was one-half the average of the past decade, but the reduction in the death-rate (1·10 for 1883) was not so great. Apoplexy.

Hepatitis in the army of India was in much the same proportion as in the preceding year. The admission-rate was 29 against 30 in 1882. The death-rate was 1·13 against 1·40 in 1882. Both the admission and death-rates were much smaller than the average ratios of the last ten-year period, and are the lowest on record since 1870. The disease was most prevalent in the Madras Army. Here the admission-rate was 41 per 1,000 and the death-rate 1·72, but these ratios are, on the whole, unfavourable as compared with the ratios of the three preceding years; they are below the average ratios of the past decade, which were—admission-rate 67 and death-rate 3·18. The next highest admission and death-rates occurred in the Bengal Army. The admission-rate was 27 and the death-rate 1·06. These ratios are the lowest on record since 1869. The results in the Bombay Army were somewhat unfavourable as compared with the preceding year, but favourable as compared with the average results of the past ten-year period. The admission-rate was 23 against 22 in 1882 and the death-rate 0·82 against 0·81. Hepatitis.

After steadily declining since 1879 the admission-rate for respiratory diseases in the whole army of India again rose, though to a small degree, during 1883. This rate was 76 as compared with 74 in 1882, and 75 the average admission-rate for 1870–79. The mortality, however, from these diseases throughout the army of India has continued to fall. It was 0·67 against 0·75 in 1882, and 0·97 the average ratio for 1870–79. The increased admission-rate above referred to was due entirely to the greater prevalence of these diseases in the Bengal Army, for only in this Presidency was there an increased admission-rate, 88 per 1,000 against 80 during the preceding year. This rate for 1883 exceeds the average ratio of 1870–79, which was 84, and still more that of 1860–69, which was 75. The Bombay Army comes next in point of frequency of admissions. In this army the admission-rate was 73 per 1,000. This ratio is higher than the average ratio of 1870–79 (64), but it is an improvement upon Respiratory diseases.

the ratios of recent years. The admission-rate in the Madras Army was 41 per 1,000, or less than one-half that of Bengal. In Madras alone is the admission-rate lower than the average ratio for the last ten-year period. The highest death-rate was recorded in the Bombay Army, 1·01, which is greater than the ratio of 1882, and still greater than the average ratio of 1870–79, which was only 0·70. In the Bengal Army the death-rate was 0·67, one of the lowest ratios on record since 1860; better results were 0·58 in 1877 and 0·54 in 1874. In the Madras Army the mortality (0·28) was almost identical with that of the preceding year (0·27) and amongst the lowest on record. The highest admission-rates were recorded in Southern Afghanistan, 179 per 1,000, Hill Stations of Bengal, 113, and Panjab, 103, and the lowest in Deccan and Nagpur, 43, Bengal, 45, and Burma and Pegu, 46.

Venereal diseases.

From the following table, which gives the admission-rates from all forms of venereal diseases in the army of India and in the three Presidencies taken separately, it will be seen that for the army, as a whole, the admissions have steadily increased. During 1870–79 the average rate was 203; since then it has risen gradually from 250 in 1880 to 270 in 1883:—

Admissions from Venereal Diseases in the three Presidencies.

Presidency.	Admissions per 1,000.					
	1860–69.	1870–79.	1880.	1881.	1882.	1883.
Bengal	265	209	276*	276*	271	281
Madras	†	198	275	258	288	289
Bombay	†	191	269	261*	224	218
India	†	203	250	260	265	270

* Excluding troops in Afghanistan.
† The statistics of Madras and Bombay, and for the whole of India for these years are not available.

As in 1882, the highest admission-rate was again recorded this year in the Madras Army, viz., 289 per 1,000. This is practically the same as it was in 1882 (288 per 1,000), and is 91 per 1,000 greater than the average admission-rate during 1870–79. It is also the highest on record. The next highest admission-rate occurred in the Bengal Army, 281. This ratio exceeds that of the preceding year by 10 per 1,000; the average of 1870–79 by 72 per 1,000, and the average of 1860–69 by 16 per 1,000. In the Bombay Army there was a reduction in the admission-rate as compared with the last five years. It was 218 per 1,000, a ratio exceeding the average of the period 1870–79 by 27 per 1,000.

Taking the statistics of venereal disease during the last 14 years, as a whole, in protected and unprotected stations, it appears that whilst for the whole of India the admission-rate for venereal diseases was 227·0 per 1,000 in unprotected stations, it was 223·1 in protected stations. There was, therefore, a small difference in favour of the protected stations. Taking the years individually for India, as a whole, in 8 of the 14 years the protected stations recorded a smaller proportion of admissions than the unprotected. The greatest difference in favour of protected stations was 70·2 per 1,000 during 1883; for whilst the admission-rate was 341·6 per 1,000 in unprotected stations, it was 271·4 in protected stations. Of the six years in which the admission-rate of protected stations exceeded the admission-rate of unprotected stations, the greatest excess was 33·2 per 1,000 in 1872. Looking next at the statistics of the three Presidencies separately during the last 14 years, it is seen that in Bombay alone were the admissions, on the whole, fewer in protected than in unprotected stations. The average admission-rate in this Presidency for the 14 years in protected stations was 209·7, and in unprotected stations 240·7. During the 14 years since 1870, only in 1870 and 1871 did the admission-rates of protected stations exceed those of unprotected stations, and of the remaining years in which the admission-rates were in favour of protected stations, the most favourable result was exhibited in 1883, when the admission-rate in protected stations was less than that in unprotected stations by 113·7 per 1,000. In Bengal and Madras, as already stated, the admission-rates in protected stations, on the whole, exceeded the rates in unprotected stations. In Bengal the rates were for protected stations 230·9, and for unprotected stations 228·1 per 1,000. In Madras for protected stations 223·0, and for unprotected stations 186·6; whilst in Bengal, 6 of the 14 years showed admission-rate results in favour of protected stations, in Madras only 3 did so. It is thus seen, that the small difference in favour of protected stations throughout India, as a whole, is due

entirely to the favourable results of Bombay. The diminution of venereal diseases in protected stations for the army, as a whole, is quite insignificant.

Invaliding.

Throughout the army of India, 1,811 men were invalided in 1883, or an equivalent of 32·66 per 1,000 of strength. This ratio is somewhat smaller than that of 1882, 33·03, and considerably smaller than the average ratio of 1870–79, which was 43·04. With the exception of the ratio of 1880, which was 26·31, it is the lowest on record since 1870. The Bombay Army contributed the largest share to this total invaliding ratio. From this army 418 men were invalided, or a ratio of 38·08 per 1,000. This ratio is higher than that of the preceding year, 35·85, and is but little less than the average ratio of 1870–79, which was 42·79. In the Madras Army the ratio was 32·70 against 24·12 in 1882, and 48·71 the average of the past decade. The smallest amount of invaliding took place in the Bengal Army, from which 1,049 men were invalided, or a ratio of 30·89. This is the second lowest ratio on record since 1870, the lowest having occurred in 1880, when it was 22·25. During the preceding year it was 34·96; the average ratio for 1870–79 was 41·40.

From the army of India, 1,073 men were invalided for change, and 702 for discharge from the service. In the case of 36 men, no information is given as to whether they were invalided for change or for discharge. Thus 39 per cent. of the total number invalided were invalided for discharge. This is a somewhat greater proportion than in either of the two preceding years. In the Bengal Army, of the total of 1,049 invalided, 574 were for change and 475 for discharge; the latter number represents 45 per cent. of the total, which is also a higher percentage than in the two preceding years. In the Madras Army, 344 were invalided in all; of these, 205 for change, and 139 for discharge, or 40 per cent. of the total. Lastly, of the 418 invalided from the Bombay Army, 294 were for change, and only 88 for discharge, or 21 per cent. of the total. Whilst, therefore, the order of the three Presidencies as regards largest total ratios of invaliding is Bombay, Madras, Bengal, as regards the seriousness of the causes of invaliding, judged by the proportions invalided for discharge, this order is exactly reversed.

Anæmia and debility, as usual, gave rise to the largest proportion of invaliding in all three Presidencies. The ratios from these causes were 4·98 in Bengal, 5·80 in Madras, and 8·56 in Bombay. With the exception of Madras, these ratios are smaller than those of the preceding year. The average ratios during 1879–79 were—

Bengal	10·23
Madras	9·78
Bombay	12·00

Compared with these, the ratios of 1883 are favourable in all cases; but the greatest improvement is shown in the Bengal Army. In the Bengal Army the next highest ratios were afforded by phthisis pulmonalis 3·24, hepatitis 3·12, diseases of the heart and arteries 2·18; in the Madras Army, hepatitis 3·23, palpitation 2·95, dysentery 2·56, phthisis 2·19, and injuries 2·18; in the Bombay Army, palpitation 3·64, fevers (including enteric) 2·82, diseases of heart and arteries 2·73, hepatitis 2·55, and phthisis 2·28.

The amount of invaliding in the British Army, due to mental diseases, has lately engaged attention, and the total number of cases in each Presidency is shown in the margin. Statistics for the whole European Army of India are only available since 1877 inclusive. The period embraced is too short to allow of any definite conclusions being drawn from the figures, but they may usefully be analysed. The ratio of invaliding from this cause during 1883, namely, 1·55 per 1,000, was greater than in any of the preceding years since 1877. Since 1880 there has been a small but steady increase year by year in this ratio. In that year the ratio was unusually low, namely, 0·87 per 1,000, the lowest on record. It rose in 1881 to 1·28, a ratio almost identical with that of 1879, and in 1882 stood at 1·35. In the army of India during 1883, mania and melancholia, with a few cases of hypochondriasis, contributed greater numbers than in any preceding year; whilst the number invalided for dementia was less than in either of the two preceding years. The approximate average ratio of invaliding from mental diseases during the whole period, 1877–1883, is 1·21, and for the armies of the three Presidencies separately the ratios were for Bengal 1·23, Madras 1·30, and Bombay 1·07. In the army, as a whole, dementia was the most frequent form of mental disease, giving rise to invaliding; melancholia with hypochondriasis next, and mania least. The differences in the numbers invalided from these three causes varied in the three Presidencies, taking all years since 1877 together. In the Bengal and Bombay Armies the excess in the number of

Total Cases of Mental Diseases.

Year.	Bengal.	Madras.	Bombay.	India.
1877	44	14	11	69
1878	40	8	8	56
1879	51	16	6	73
1880	39	7	6	52
1881	39	18	18	75
1882	48	15	14	77
1883	54	19	13	86

cases of dementia was marked; but in the Madras Army all three forms contributed almost equally. In the Bengal Army melancholia with hypochondriasis is on the whole more frequent than mania; but in the Bombay Army both forms occur in almost equal proportions.

Of the total number invalided from the army of India, 36·55 per cent. were under 25 years of age. This is a higher ratio than usual, the ratios for the last few years having been 31·82 in 1882, 33·74 in 1881, and 35·84 in 1880. There was, however, a decrease in the percentage of those between 25 and 29 years of age as compared with the preceding year, viz., 32·36 against 35·31 in 1882. The percentage invalided between 30 and 34 years of age was 15·68 against 18·39 in 1882. With reference to the effect of length of residence in India upon invaliding, the largest percentage occurred as usual amongst men of from 2–5 years' residence. During 1883, 57·81 per cent. of the men invalided were between these lengths of service. This ratio is nearly identical with that of the preceding year, but is considerably higher than that of 1880 (36·54). The next highest percentage occurred amongst men under two years' service. This was 18·94 against 17·35 in 1882. Both these ratios are much smaller than that for 1880, which was 31·12. Whilst a greater number of men of from 2–5 years' residence have been invalided year by year since 1880, a smaller number of men under two years' service have been thus lost to the army. The excess and the diminution do not, however, balance one another. There is a greater excess of loss amongst men of 2—5 years' residence than the diminution among men of under two years' service.

The strength of newly-arrived regiments was comparatively small. It was 1,453 as compared with 3,344 in 1882. Their health statistics, as compared with those of the army generally, are more unfavourable on the whole than they were in 1882.

Experience of Newly-arrived Regiments in 1883 (*during their First Year of Indian Residence*).

—	Strength.	Ratio per 1,000 of Strength.							
		Admission-rate.	Daily Sick-rate.	Death-rate.	Deaths from				
					Enteric Fever.	Other Fevers.	Apoplexy.	Dysentery and Diarrhœa.	Hepatitis.
Army generally -	55,525	1,335·7	62·9	10·88	2·40	·46	1·10	·42	1·13
New regiments -	*1,453	1,737·8	82·6	19·96	8·95	—	4·82	—	·69

* Excluding the statistics of the men of the 2nd Derbyshire Regiment at Naini Tal.

The admission and daily sick-rates amongst newly-arrived men were considerably in excess of the same rates for the army generally. The difference in the total death-rates was also very marked, much more so than in 1882; for whilst in that year the difference amounted to 4·42, during 1883 the difference was 9·08. The death-rate from enteric fever among newly-arrived soldiers as usual was high, 8·95 as compared with 2·40 for the army as a whole, showing a difference of 6·55 compared with a similar difference of only 4·65 in 1882. Newly-arrived men suffered much more severely from apoplexy than they did in 1882. The death-rate for the army as a whole was 1·10 against 0·82 in 1882, whilst for newly-arrived men the rate was 4·82 against 0·60 in 1882. They suffered less from ordinary fevers and hepatitis. These results are brought together in the above table. It may be mentioned that the statistics given in this paragraph and in corresponding paragraphs of former reports, embrace a period of a complete year from the date of arrival of the regiments concerned in India. They differ, therefore, from the results given in the tables of the Appendix, which have all reference to the calendar year.

Sickness and mortality among women and children.

The number of women in the army of India has fallen very considerably since 1875. The strength during 1883, 3,290, has been only about one-half that of 1875 (6,335). With this decrease in the number of women there has naturally been a corresponding decrease in the number of children, the average number of children during 1883, 6,015, being also about half that of 1875, 12,359. The death-rate among women was 21·28,—a ratio somewhat greater than that of 1882, but nevertheless lower than 25·09, the average ratio during 1870–79. The death-rate for children was 46·88,—a very favourable ratio since the average during 1870–79 was 68·96. Amongst women, as usual, childbirth and

abortion caused the largest proportion of deaths. The death-rate from these causes was 3·65,—a somewhat higher ratio than usual, the average during 1870–79 having been 2·93. Phthisis gave rise to the next highest death-rate, 3·35. This is also higher than the average ratio of 1870–79, which was 2·78. Compared with the average ratios of the past decade, cholera, malarial fevers, apoplexy, bowel complaints, hepatitis, and anæmia and debility, all yielded smaller death-rates during 1883. The reduction in the death-rates from malarial fevers, cholera, and bowel complaints was most marked. Of the three Presidencies, the highest admission-rate occurred in Bengal (879), and the lowest in Madras (790); but the highest mortality was recorded in Bombay (27·30), and the lowest in Madras (16·71). In Bengal the chief cause of death was childbirth and abortion; in the Madras Army it was phthisis and sunstroke; whilst in Bombay, childbirth, abortion, and phthisis contributed equally.

Among children the greatest number of deaths resulted from diarrhœa (8·48 per 1,000), convulsions (8·31), anæmia and debility (5·65), dentition (4·49), bronchitis and pneumonia (3·66), and tabes mesenterica (3·49). Comparing these rates with the average rates during 1870–79, the mortality from tabes mesenterica alone was greater. There was a considerable reduction in the death-rates from diarrhœa, dentition, and convulsions. Diarrhœa caused the largest mortality in Madras (9·27) and the smallest in Bombay (6·59); convulsions the largest in Madras (8·60) and the smallest in Bombay (7·53); whilst dentition caused the largest proportion of deaths in Bombay (6·59) and the smallest in Madras (3·97). Two cases of enteric fever are reported. They were both in Bengal, and both terminated in recovery. Two cases of cholera occurred—one in Bengal, which recovered, and the other in Madras, which died. Fifteen cases of small-pox occurred, two of which ended fatally.

Mortality among officers.

In former Annual Reports the statistics of deaths and causes of deaths among officers related only to the officers of the Bengal Army. Information of a similar nature regarding the officers of the Madras and Bombay Armies has been supplied by the Adjutant-General in India since 1881.

During 1881, throughout the army of India there were in all 6,509 officers, of whom 3,152 belonged to the British service and 3,357 to the Indian service. Of the officers of the British service 52 died, or an equivalent of 16·49 per 1,000. Among the officers of the Indian service 50 died, or in the proportion of 14·89 per 1,000. The mortality in both services together equal 15·67 per 1,000. In 1881 the death-rates for the Presidencies separately were as follows :—

Bengal:	both services combined	=18·85
	British service alone	=20·10
	Indian service alone	=17·48
Madras:	both services combined	=10·36
	British service alone	= 6·36
	Indian service alone	=13·11
Bombay:	both services combined	=12·76
	British service alone	=15·41
	Indian service alone	=10·46

During 1882, there were 6,163 officers of both services in the army of India. Of these 75 died, or a ratio of 12·16 per 1,000. Of the total number of officers, 3,002 belonged to the British service and 3,161 to the Indian service. Amongst the former there were in all 34 deaths, or a proportion of 11·32, and amongst the latter 41, or a proportion of 12·97. The results for the Presidencies separately are as follows :—

Bengal:	both services combined	=11·28
	British service alone	=11·02
	Indian service alone	=11·58
Madras:	both services combined	=12·89
	British service alone	= 9·82
	Indian service alone	=15·08
Bombay:	both services combined	=13·77
	British service alone	=13·89
	Indian service alone	=13·67

The total number of officers in the army of India during 1883 was 6,115, of whom 2,900 belonged to the British Army and 3,215 to the Indian Army. Among the officers of both services 75 deaths occurred, equal to a ratio of 12·2 per 1,000. 34 of these deaths were among officers of the British Army and 41 among those of the Indian Army, or in the ratios

of 11·7 and 12·7 per 1,000 respectively. The death-rates in the Presidencies separately were as follows :—

Bengal :	both services combined	= 13·22
	British service alone	= 13·90
	Indian service alone	= 12·50
Madras :	both services combined	= 11·9
	British service alone	= 6·7
	Indian service alone	= 15·5
Bombay :	both services combined	= 9·9
	British service alone	= 9·7
	Indian service alone	= 10·0

Native Troops.

Sickness and mortality in 1883.

In the Native Army of India as in the European Army, the results were on the whole favourable. The admissions equalled 923 per 1,000 and the daily sick 31. These ratios are the lowest on record since 1877, when the statistics for the whole army of India were for the first time combined. From the following table it will be seen that the ratios of 1883 are a considerable improvement upon the average ratios of the period 1877–81, and that in respect of some items they are lower than even the ratios of 1877, which was a remarkably healthy year. The total mortality in 1883 was 11·76 per 1,000, or 14·31 including men absent from their regiments. These are very favourable ratios, and are about one-half the average ratios of 1877–81. Cholera contributed a fraction more to the death-rate than in the preceding year, but the mortality under this head was, nevertheless, smaller than usual.

Year.	Average Strength.	Ratio per 1,000.				Mortality, including absent Deaths.
		Admissions into Hospital.	Daily Sick.	Deaths from		
				Cholera.	All Causes.	
1877–81	113,669	1,422	48	1·94	24·90	27·40
1877	113,966	1,030	32	1·53	16·90	13·38
1878	117,278	1,469	43	2·06	18·04	21·02
1879	121,102	1,735	58	4·61	35·15	37·79
1880	126,385	1,546	56	0·53	39·22	41·12
1881	114,612	1,305	46	0·97	19·24	22·62
1882	114,894	1,129	37	1·02	12·24	14·76
1883	114,830	923	31	1·15	11·76	14·31

Malarial fevers, as usual, gave rise to the largest number of admission, the rate for them having been 387·4 per 1,000, against 553·5 in 1882. There was, therefore, a considerable decrease of these fevers. The next lowest admission-rate recorded under this head during the previous six years was 482·6 in 1877; the highest 978·1 in 1879. After fevers, wounds and accidents gave rise to the next largest admission-rate, namely, 108·2. Dysentery and diarrhœa gave rise to an admission-rate of 60·9, or somewhat less than that of the preceding year, which was 70·1, but considerably lower than the remaining years since 1877, when it varied from 80·3 in 1877 to 177·1 in 1879. The admission-rate for respiratory diseases was 52·9. This ratio is but little greater than it was in 1877 (50·1), but considerably lower than the ratios which prevailed from 1878–81, when a large proportion of troops was engaged on active service. For enteric fever the admission-rate was 0·2, the same as it had been during the two previous years. Since 1877 there has been practically no variation in the admissions returned as due to this disease, but the degree of fatality varied considerably. The percentage of deaths among those treated was 27·78, the lowest since 1877, the highest having occurred in the preceding year 1882, when it was 58·33. Respiratory diseases, as usual, were the cause of the largest mortality, the death-rate per 1,000 having been 3·91. These diseases have of late years given rise to comparatively high death-rates. During 1879 and 1880 the rates were 10·0 and 12·30, respectively, due probably to exposure of a large number of troops whilst on active service. The ratio of 1883 does not differ much from the ratios of 1877 and 1878, which were 2·12 and 3·83. The next highest mortality resulted from fevers, namely, 1·41 per 1,000. This is the lowest rate on record since 1877; the next lowest having been, in 1882, 1·76, and the highest, in 1880, 6·73. Cholera gave rise to the next highest ratio, namely, 1·15 against 1·02 in 1882.

Bengal army.

The results as respects the Bengal Native Army which are tabulated in the following statement show that both as regards sickness and mortality the year 1883 was very favourable; the admission-rate 985, daily sick-rate 32, and death-rate 10·55 among those present with their regiments, were among the lowest on record since 1867:—

Year.	Average Strength.	Ratio per 1,000.			Mortality, including absent Deaths.
		Admissions into Hospital.	Daily Sick.	Deaths from	
				Cholera.	All Causes.	
1867–76	39,508	1,360	42	2·12	13·84	17·25
1877	39,649	1,097	34	0·35	10·32	13·63
1878	41,116	1,645	49	2·09	22·59	25·57
1879*	31,116	2,023	68	2·80	31·78	53·61†
1880*	30,365	1,609	65	1·52	33·85	53·15†
1881*	36,896	1,495	51	0·92	19·76	27·73†
1882	40,256	1,250	41	0·72	13·34	16·49
1883	40,932	985	32	0·56	10·55	13·98

* Excluding troops in Afghanistan.
† These ratios are calculated on the total regimental strength, including the army in Afghanistan.

As regards the prevalence of sickness, the admissions due to the chief diseases were less numerous than those of the preceding year, except in the cases of remittent fevers, apoplexy, hepatitis, phthisis, and wounds and accidents, but in all of these the excess during 1883 was trivial. Compared with the average admission-rates of the period 1867–76, respiratory diseases, phthisis, eye diseases, abscesses and ulcers, wounds and accidents, only gave rise to slightly higher ratios in 1883. The reduction in the admission-rate for intermittent fevers was particularly striking, namely, 398 against 606 per 1,000 in 1882, and against an average rate of 691 during 1867–76. Respiratory diseases, phthisis, and smallpox were the only diseases which gave rise to a higher mortality during 1883 than the averages of 1867–76. During 1883 the mortality from respiratory diseases was 3·20, whilst the average is 2·57, and for phthisis it was 1·07, against an average of 0·77. From smallpox the ratio was ·29 in 1883 against ·20 during 1867–76. Compared with the preceding year, however, the mortality from respiratory diseases was less. This is satisfactory as showing that the tendency to a diminishing mortality, noticed in the last two annual reports, still continued. The mortality from cholera was small; 38 cases occurred, of which 23 died, or a percentage of 60·53. The severity of the disease was therefore great. Smallpox was unusually prevalent; 50 cases were treated (1·2 per 1,000 of strength), of which 12 died, against 21 cases and 5 deaths in 1882. Enteric fever appears as the cause of 12 admissions, and of these three ended fatally, or a percentage of 25 of those treated. During the preceding year 11 cases were recorded, but seven of them proved fatal, yielding the high death percentage of 63·64. The cases of fever returned as enteric which occurred during the year under review were therefore comparatively mild.

The admission and death-rates among the troops of the several geographical groups of the Bengal Army for a series of years are given side by side in the following table:—

Year.	Ratio per 1,000.									
	Bengal Proper and Assam.		Gangetic Provinces.		Rohilcund and Meerut.		Agra and Central India.		Punjab.	
	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.
1867–76	1,523	19·13	1,062	8·38	987	11·19	1,588	9·61	1,459	14·24
1877	1,492	19·64	768	5·19	642	9·52	906	7·41	1,243	8·85
1878	1,527	22·13	1,036	7·88	1,008	9·83	1,581	12·96	1,896	18·33
1879	1,816	25·57	1,658	11·05	2,038	36·17	2,303	16·07	2,173	47·64
1880	1,757	40·63	1,222	20·50	1,395	24·46	1,884	28·52	1,687	38·02
1881	1,772	22·53	1,260	15·78	1,378	15·67	1,380	9·35	1,521	22·86
1882	1,569	18·22	1,081	10·01	1,083	9·98	1,248	7·18	1,268	13·30
1883	1,408	16·23	970	8·17	978	11·53	906	5·77	830	10·80

The results of the Agra and Central India group are again, as they were during the previous two years, the most favourable on the whole. The admission-rate in this group is certainly higher than it was in the Punjab; but the death-rate, 5·77 per 1,000, is remarkably low, being nearly one-half that in the Punjab, and one-third that in Bengal Proper and Assam. The Gangetic Provinces come next in order of favourable results. In this group the admission-rate was but slightly in excess of that in the Agra and Central India group; the excess in the mortality (8·17) was more marked. In the above table it will be seen that the average death-rate in this group during the period 1867–76 was the lowest of all the groups, and the mortality of the year under review is a little less than the average. In Bengal Proper and Assam as usual with the Native army sickness was most prevalent and the mortality highest. Comparing the death-rate of 1883 with the average death-ratios of 1867–76, the Rohilcund and Meerut group alone was in excess of the average, but the excess was small (0·34 per 1,000). In the Agra and Central India and Punjab groups the diminution of mortality was most marked: in the former group it was 3·84 per 1,000 less than the average, and in the latter 3·44. In the Gangetic Provinces and Oudh the mortality was but slightly less than the average. In the Bengal Proper group the diminution was nearly 3 per 1,000.

In every group there was a diminished prevalence of fevers as compared with 1882; this was most marked in the Agra and Central India and Punjab groups, where the admission-rates for 1883 were nearly half those of the preceding year. If the admission-rates for fevers given below are compared with the average admission-rates of the ten-year period 1867–76, it will be found that in the first group alone the rate of 1883 exceeded the average ten-year ratio. The rates in Agra with Central India and in the Punjab were considerably less than the average rates, which are 877 and 873 per 1,000 respectively. In every group bowel complaints were also less prevalent than in 1882, and still less so than the average of 1867–76. Compared with this average the diminution was most marked in the Agra with Central India and in the Punjab groups, where the admission-rates of 1883 were less than a half of the average ratios of the ten-year period (92 and 102 per 1,000 respectively). Respiratory diseases were, on the whole, less prevalent than in 1882, but only in the Punjab group was the diminution at all marked. Compared with the ten-year averages (1867–76) the admission-rate in the Punjab under this head was somewhat less; in the Rohilcund and Meerut group it was the same, but in the remaining groups the ratios of 1883 were higher.

Chief Causes of Sickness in the several Groups of Cantonments of the Bengal Presidency.

Groups.	Ratio of Admissions per 1,000 of Strength.					
	Fevers.	Bowel Complaints.	Spleen Diseases.	Respiratory Diseases.	Rheumatism.	Abscess and Ulcer.
Lower Bengal and Assam	708	181	10	74	33	79
Gangetic Provinces	336	47	5	53	48	133
Rohilcund and Meerut	418	49	3	38	33	119
Agra and Central India	321	35	7	44	33	192
Punjab	351	46	10	49	29	92

Cholera gave rise to the largest mortality in Lower Bengal and Assam; here it equalled 1·80 per 1,000 against 3·01 in 1882. The average during 1867–76 was 3·10. In the Gangetic Provinces and Oudh the death-rate from cholera was 1·17 against 0·85 in 1882, and 1·49 the average mortality of the ten-year period. In the Rohilcund with Meerut and in the Punjab groups the loss from cholera was small, and in the Agra and Central India group there were no deaths from this disease. In the preceding year all three of these groups were without any death from cholera. Fevers contributed most largely to mortality in Lower Bengal and Assam. The death-rate was 2·46 against 3·01 in 1882. There was a great reduction in the mortality from this cause in the Punjab, where the death-rate was only 0·79 against 2·11 in 1882, and an average of 3·32 during 1867–76. In every group, except Rohilcund and Meerut, the death-rate during 1883 was less than in 1882, and in that group the excess was trifling—1·90 in 1883 against 1·82 in 1882. As usual bowel complaints were most fatal in Lower Bengal and Assam. The death-rate there was 3·28 against 4·97 in 1882; but the latter ratio was greater than the average of the ten-year period 1867–76, which was 3·80. In every other group the ratios of 1883 are considerably lower than the ten-year averages. The mortality due to respiratory diseases was in all cases

less than it had been in 1882, but in all the groups, except Agra and Central India, it was greater than the averages of the ten-year period. The total mortality from all causes was highest in Lower Bengal and Assam, 16·23. Next in order come Rohilcund and Meerut, Punjab, Gangetic Provinces, and lastly Agra and Central India. With the exception of Rohilcund and Meerut, all groups compare favourably with the results of the preceding year, and with the average results of 1867–76. In this group the mortality of 1882 was 9·98, and the average mortality 11·19.

Chief Causes of Mortality in the several Groups of Cantonments of the Bengal Presidency during 1883.

Groups.	Ratio per 1,000.				
	Cholera.	Fevers.	Bowel Complaints.	Respiratory Diseases.	Total.
Lower Bengal and Assam	1·80	2·46	3·28	2·46	16·23
Gangetic Provinces	1·17	1·30	0·26	1·82	8·17
Rohilcund and Meerut	0·34	1·90	0·34	2·75	11·53
Agra and Central India	0·00	0·99	0·40	1·99	5·77
Punjab	0·07	0·79	0·72	4·97	10·80

Omitting hill stations, which were occupied only for a portion of the year, Edwardesabad was the only place in which the admission-rate exceeded 2,000 per 1,000. Here it equalled 2,217 against 2,297 in 1882. In seven stations the admission-rate varied between 1,500 and 2,000. In the preceding year six stations recorded admission-rates above 2,000, and fifteen stations between 1,500 and 2,000.

The highest death-rates occurred in the following stations:—

Edwardesabad and outposts	39·19	Mooltan	24·76
Shillong and outposts	25·92	Baxa	21·79
Dharmsala and Kangra	25·91	Dera Ismail Khan	29·81
Kohat and outposts	25·86		

There were thus seven stations in which the mortality exceeded 20 per 1,000 against 6 in 1882. In Edwardesabad, of the 70 deaths which occurred in all, 59 were due to respiratory diseases; in Kohat 45 of 65, in Mooltan 20 of 26, and in Dera Ismail Khan 23 of 40, were due to the same cause. In Dharmsala 11 of 15 deaths were due to phthisis. In Shillong and Baxa the mortality was due to various diseases.

There was a satisfactory reduction in sickness and mortality among the small body of Bengal troops serving in Southern Afghanistan. The mortality among these troops during the preceding two years was very great, but during 1883 it fell from 36·10 during three months of 1882, and 106·30 for the year 1881, to 3·21 during seven months of occupation in 1883. The average strength of the force was only 624, and two deaths, one in hospital and one out of hospital, gave rise to the ratio. The death in hospital was due to respiratory disease. The admission into hospital equalled 910 per 1,000. The chief causes of admission were intermittent fevers, wounds and accidents, and bowel complaints.

With a considerable reduction in the admission and daily sick-rates, as compared with previous years since 1877, there was an increased death-rate among men present with the Punjab Frontier Field Force as compared with the two preceding years. The chief causes of admission were intermittent fevers, respiratory diseases, abscesses and ulcers, and bowel complaints. The admission-rates for intermittent fevers, bowel complaints, and abscess with ulcers were less than the average rates during 1867–76; but the rate for respiratory diseases was greater, as under this head the rate of 1883 was 109, whilst the average for the ten years was only 66. In this force there were in all 224 deaths, of which no less than 148, or 14·18 per 1,000 of a strength of 10,438, were due to respiratory diseases. During the preceding year, out of 169 deaths, 98, or 8·77 per 1,000 were due to the same cause. The excess of mortality during 1883 over that of the preceding year was almost wholly due to the increased mortality from respiratory diseases. The largest number of these deaths took place in Kohat and Edwardesabad with their outposts, as was the case in 1882. In these stations 104 of the whole 148 occurred.

The statistics of the Central India regiments were extremely favourable. Of an average strength of 5,197 the admission-rate was 595, the daily sick-rate 19, and the mortality 7·89,

or including absent deaths 10·16. These ratios were lower than in any year since 1877; they are also favourable when compared with the average results of 1867–76, during which time the admission-rate was 1,020, the daily sick-rate 35, and the death-rate 11·10. Remittent and continued fevers gave rise to the largest number of deaths, viz., 10; whilst respiratory diseases proved fatal in 7 cases. The admissions for guinea-worm, which were remarkably numerous in 1882, were much fewer during 1883—only 88 cases against 155. More than one-half the total number of these cases occurred in the Meywar Bheel Corps, in Kherwarra.

As in the preceding year, the statistics of the Hyderabad Contingent were more favourable than those of any other section of the Native Army. The admission and daily sick-rates (572 and 20 per 1,000 respectively of an average strength of 6,983) were lower than in any year since 1877, while the mortality (7·59 per 1,000, and including absent deaths 9·31), though still very low, was much greater than the exceptionally low mortality of the preceding year (4·47). The greater mortality during 1883 was due mainly to a larger number of deaths from cholera, diarrhœa, hepatitis, and anæmia.

Madras army.

The health of the Madras troops was good. Both sickness and mortality were less than in any of the previous six years. The chief causes of admission were intermittent fevers, abscesses and ulcers, wounds and accidents, and bowel complaints. From all these, however, the admission-rates were lower than those for the preceding year. Cholera and small-pox gave rise to a greater number of admissions than in 1882. There were in all 173 cases of cholera with 81 deaths, or a percentage of 46·82 of those treated. During the preceding year there were 116 cases with 73 deaths, or a percentage of 62·93. In 1883 there were 77 cases of small-pox against 40 in 1882, and only 4 of the 77 proved fatal.

Sickness and Mortality during the last seven years, compared.

Year.	Average Strength.	Ratio per 1,000.				Mortality, including absent Deaths.
		Admissions into Hospital.	Daily Sick.	Deaths from		
				Cholera.	All Causes.	
1877 - - -	28,304	861	28	2·79	11·80	14·36
1878 - - -	28,728	841	29	2·23	12·25	15·49
1879 - -	27,314	1,269	43	3·19	18·89	21·23
1880 - - -	28,710	1,399	54	0·10	15·57	19·54
1881 - -	28,533	997	41	1·37	12·92	16·75
1882 - - -	27,654	879	30	2·64	12·01	14·99
1883 - -	27,703	737	27	2·92	10·76	12·51

As regards sickness and mortality in the various regiments of Madras troops, the highest admission-rate occurred in the detachment of the 2nd Native Infantry at the Nicobar Islands. This small detachment of 51 men registered an admission-rate of 7,216. They suffered almost exclusively from fevers. The next highest rate, 1,752, occurred in a wing of the same regiment at Port Blair. Omitting small bodies of men, the highest admission-rates occurred in the following: the 16th Native Infantry at Raipur, 1,391 per 1,000; the 24th Native Infantry at Secunderabad, 1,099; and the Sappers and Miners at Bangalore, with detachments at Sitabaldi, Rangoon, and Cotacamund, 1,000. At Raipur, fever, anæmia, abscesses with ulcers, and injuries gave rise to the largest number of admissions. At Secunderabad the 24th Native Infantry suffered mostly from fevers, abscesses and ulcers, dysentery and diarrhœa, and venereal diseases. In the Sappers and Miners, in addition to fevers, numerous admissions took place from injuries, abscesses with ulcers, dysentery and diarrhœa, and rheumatic affections. The largest number of deaths, 29, occurred in the 9th Native Infantry at Secunderabad. Three of these deaths were due to beri-beri, and 9 to respiratory diseases; 21 deaths occurred in the 5th Native Infantry at Kamptee, 8 of which were due to cholera. In the 10th Native Infantry at Vellore, and in the 30th Native Infantry at Trichinopoly, 20 deaths occurred. In the one 18 of the total were due to cholera, and in the other 15. In the 29th Native Infantry, which was quartered during the greater part of the year at Vizagapatam, there were 31 cases of beri-beri, 5 of which proved fatal. The statistics of that portion of the Madras Army serving in Hyderabad and Nagpur were not so favourable as in 1882. Sickness was somewhat more prevalent, and the death-rate higher, viz., 18·50

against 11·58. There was a very considerable improvement in the health of the troops serving in the Northern Division of the Madras Army as compared with the preceding year. The admission-rate fell from 1,559 to 710; the daily sick from 44 to 27, and the death-rate from 13·97 to 7·93. There was an improvement also in the health of the troops in Southern India and in Burma and the Andamans.

Bombay Army.

The health of the Bombay Army was on the whole much the same as it had been in 1882. The admission and daily sick-rates were slightly less, but the death-rate somewhat higher. These results are set forth in the following table:—

Sickness and Mortality during the last seven years, compared.

Year.	Average Strength.	Ratio per 1,000.				Mortality, including absent Deaths.
		Admissions into Hospital.	Daily Sick.	Deaths from		
				Cholera.	All Causes.	
1877	23,388	1,074	33	1·93	10·90	12·96
1878	23,672	1,702	45	2·86	15·12	17·95
1879	22,854	1,663	51	3·11	20·22	21·90
1880*	15,328	1,283	45	—	10·44	56·53‡
1881*	18,349	1,166	41	1·85	14·01	25·93‡
1882†	23,772	1,067	36	0·46	12·16	13·41
1883	23,576	994	35	0·47	12·81	14·96

* Excluding Afghanistan. † Including troops in Southern Afghanistan.
‡ These ratios are calculated on the total regimental strength, including the army in Afghanistan.

Throughout the army of the Presidency there were only 21 cases of cholera, and of these 11 were fatal. Small-pox gave rise to 104 admissions against 25 in 1882. Of these, however, only two proved fatal. Bowel complaints were also more prevalent than in 1882, having equalled 70·2 against 64·0 per 1,000. The other chief diseases were less prevalent. Respiratory diseases caused the largest number of deaths—109 out of a total of 302 from all causes. Of remittent and continued fevers, 36 proved fatal against 16 in the preceding year.

Of the several portions of the Bombay Army, the force serving in Southern Afghanistan suffered most. The admission-rate in it was 1,741 per 1,000, the daily average sick 56, and the death-rate 37·64. All these ratios considerably exceed the ratios for the Bombay Army as a whole. Both the admission-rate and the daily average sick ratio of 1883 were, however, smaller than in 1882, but the death-rate was greater—37·64 against 35·80. Intermittent fevers, respiratory diseases, and bowel complaints gave rise to the largest number of admissions; the numbers admitted from the first two causes were, however, considerably less than they were during 1882. There were in all 149 deaths, 74 of them being due to respiratory diseases; 15 were due to remittent and continued fevers, against 6 in 1882. Enteric fever was entirely absent from among them. Next in order of sickness comes the Northern Division, in which the admission-rate was 956, and the daily sick-rate 33 per 1,000. Both these ratios are a little in excess of those for 1882. The death-rate, however, was small—5·47 against 7·78 in 1882. The admission-rates in the remaining three divisions of the Bombay Army were much the same; in Aden and Sind 779 per 1,000, in Konkan 774, and in Kandeish 754. Small-pox was most prevalent in Kandeish, 71 of the whole number of cases in the Bombay Army (104) having occurred there. In Aden and Sind the death-rate was 13·91 against 7·19 in 1882; in Konkan it was 9·74 against 11·17, and in Kandeish 5·33 against 6·26.

The highest admission-rate (2,241) was recorded in the Sappers and Miners at Kirki with detachments at Quetta and Aden; but the death-rate was only 10·25. High admission-rates prevailed in all the regiments serving in Southern Afghanistan. The 12th Native Infantry suffered most, with an admission-rate of 2,010 and a death-rate 67·50. Fevers and respiratory diseases contributed most largely to this mortality. Sickness was very prevalent in No. 2 Mountain Battery at Poona; the admission-rate was 1,391 per 1,000, but there was no death. Scurvy gave rise to the largest number of admissions in the Southern Afghanistan force, and especially in the 7th and 12th Native Infantry regiments; in the former 60 cases were admitted, of which 8 died; and in the latter 70 cases with 5 deaths. With regard to sickness in particular stations, it may be noted that as usual the highest proportion of admissions is recorded in the stations on the Persian Gulf, the ratio during 1883 having

been 1,846 against 1,785 in 1882. The next highest ratios occurred in Mehidpur, 1,514; Rajkot, 1,349; Dwarka, 1,345; and Surat, 1,302. At Dwarka and Mehidpur, however, there were very small detachments of 84 and 35 men, respectively. The highest death-rates were in Hyderabad, 19·23; Surat, 12·24; and Kaladgi, 12·05.

The main facts regarding the sickness and mortality in the Native Army of the three Presidencies are compared in the following table:—

Presidency.	Total Deaths per 1,000, including Absentees.	Average Strength present with Regiments.	Ratio per 1,000.			
			Admissions into Hospital.	Daily Sick.	Deaths from Cholera.	Deaths from all Causes.
Bengal Native Army - -	13·98	40,932	985	32	0·56	10·55
Madras „ „ - -	12·51	27,703	737	27	2·92	10·76
Bombay „ „ - -	14·96	23,576	994	35	0·47	12·81
Central India Regiments - -	10·16	5,197	595	19	0·39	7·89
Punjab Frontier Field Force -	23·35	16,438	1,419	45	—	21·46
Hyderabad Contingent - -	9·31	6,983	572	20	2·15	7·59
India - - - -	14·31	114,830	923	31	1·15	11·76

It will be seen that in respect of both sickness and mortality the troops of the Punjab Frontier Field Force, as has frequently happened, suffered most. Next to the Punjab Frontier Field Force the Bombay troops recorded the most unsatisfactory results. The most favourable results were yielded by the Hyderabad Contingent and the Central India and Rajputana regiments. Compared with the preceding year, the statistics of the Bombay Army were on the whole much the same; those of the Bengal Army, the Madras Army, the Central India Regiments, and the army of India as a whole, were more favourable; whilst in the Punjab Field Force and Hyderabad Contingent there was an increase in mortality.

The Aka Expedition.

Towards the close of the year a military expedition against the Akas was organised. The force was composed entirely of Native troops. It consisted in all of 30 officers, 1,028 men and 1,993 followers, and it crossed the frontier on the 17th December 1883. The object was speedily accomplished, and on the 21st January 1884 the troops began to return. By the 1st February nearly all of them were back at Tezpur. Surgeon-Major E. R. Johnson, the principal medical officer with the force, submitted a very carefully-prepared medical history of the expedition, which will be found in full in the Appendix. The report besides contains much useful information regarding the natural history of the country, and the remarks regarding the Pipsu fly and the nature of the poison used by the Akas in their arrow-heads are especially interesting. The bites of the Pipsu flies caused considerable inconvenience. The poison used on their arrows is believed to be derived from a species of monk's-hood (*Aconitum ferox*). The chief causes of admission into hospital among the troops were ague and dysentery; but the followers suffered in addition considerably from diarrhœa and respiratory diseases. Only one death from disease occurred among the soldiers, and that was from pneumonia.

Egypt Expeditionary Force.

Since the publication of the last Annual Sanitary Report, in which details regarding the health of the troops engaged in Egypt during 1882 were given, the Principal Medical Officer of the Indian Division has submitted a full report of the medical transactions of that division. As this report would doubtless interest many medical officers, it is reproduced in the Appendix.

Jails.

Sickness and mortality in jails.

Throughout India, the prisoners were, on the whole, very healthy. The admissions into hospital equalled 996 per 1,000, a considerable reduction upon the ratios of recent years, and somewhat less even than the average of the five-year period 1872–76, which preceded the famine. Compared with the results of the five years, 1877–81, which includes the famine, the reduction in 1883 has been in every respect most marked. The daily average sick-rate was 36, the lowest on record since 1877, when the statistics of all the jails in India were for the first time amalgamated. The diminished sickness as compared with the year previous is mainly attributable to the reduction in intermittent fevers; whilst in 1882 the admissions from fevers equalled 513 per 1,000, they fell in 1883 to 352. There was also a very satisfactory reduction in bowel complaints and respiratory diseases.

Statement showing the Strength, Sickness, and Mortality among the Prisoners of India during the Years 1872–76, 1877–81, *and the Years* 1880 *to* 1883.

Year.	Average Strength.	Ratio per 1,000.				
		Admissions into Hospital.	Daily Sick.	Deaths from		
				Cholera.	Dysentery and Diarrhœa.	All Causes.
1872–76 - -	99,758	1,016	?	2·86	13·48	36·24
1877–81 - -	112,670	1,189	44·9	4·48	24·97	63·01
1883 - -	88,174	996	36	2·28	10·64	31·37
1882 - -	94,063	1,214	42	2·75	15·21	39·96
1881 - -	100,844	1,214	45	3·03	16·92	44·93
1880 - -	106,768	1,213	46	0·74	19·43	48·31

The mortality from cholera was 2·28 per 1,000, a ratio but little less than that of the preceding year (2·75), but somewhat under the average for the period 1872–76 (2·86). It was, however, but one-half of the average of the years 1877–81 (4·48). Excluding cholera, the deaths from other causes equalled 29·09. The mortality due to bowel complaints fell during 1883 to 10·64 per 1,000, a smaller ratio than for any year on record since 1877. During the ten years 1872–81, the mortality under this head was 20·55.

The average strength of prisoners yielding these results was 88,174, or less by 11,584 than the average during 1872–76 before the famine-evidence not only of the complete subsidence of the disturbing influences of that calamity, but also of general prosperity among the people. Whilst in 1882 the proportion of prisoners to the general population was 4·6 per 10,000, it fell in 1883 to 4·5. The general results in relation to the population of the three Presidencies are shown in the following table :—

Ratio of Prisoners per 10,000 *of Population in each of the Three Presidencies for* 1883, 1882, 1881, 1878, *and* 1872–76, *compared.*

Presidency.	Period.	General Population according to Census of 1881.	Prisoners.		
			Average Number.	Proportion to 10,000 of Population.	Deaths per 1,000 of average Strength.
Bengal - - - -	1872–76	47,215,384	68,328	4·6	39·39
	1878		78,116	5·3	65·85
	1881		63,478	4·3	44·42
	1882		59,489	4·0	42·56
	1883		54,982	3·7	34·28
Madras - - - - -	1872–76	31,170,631	9,607	3·1	32·37
	1878		21,315	6·8	125·92
	1881		10,332	3·3	41·91
	1882		8,752	2·8	42·62
	1883		7,666	2·5	29·87
Bombay - - - -	1872–76	16,454,414	8,011	4·9	26·61
	1878		13,139	8·0	118·27
	1881		9,910	6·0	41·88
	1882		8,845	5·4	33·35
	1883		7,806	4·7	34·33

The deaths from all causes equalled 31·37 per 1,000, a ratio which is considerably less than that of 1882 (39·96), and is also lower than the average of the period 1872–76 (36·24) preceding the famine. In the succeeding five years, which include the famine period, the mortality (63·01) was more than double what it was in 1883.

As has frequently happened in former years, the statistics of the Bengal Presidency are, on the whole, unfavourable when compared with those of Madras and Bombay. In the

following table it will be observed that the ratios of the Bengal Presidency are the highest under every head, except the total mortality, and here Bombay is in excess by a fraction:—

Presidency.	Average Strength.	Ratio per 1,000.				
		Admissions into Hospital.	Daily Sick.	Deaths from		
				Cholera.	Dysentery and Diarrhœa.	All Causes.
Bengal	54,982	949	32	2·35	12·93	34·28
Madras	7,666	861	32	1·96	12·78	29·87
Bombay	7,806	734	27	2·05	6·79	34·33

Although the admission-rate for Bengal (949) is highest, it does not exceed the ratios of Madras (861) and Bombay (734) so much as in 1882. Compared with Madras, the excess is small, but it is much greater when compared with Bombay. The daily average sick-rate in the Bengal and Madras Presidencies was practically the same, 32 per 1,000; in Bombay it was only 27. In the mortality from cholera there was no great difference in the three Presidencies, for in Bengal the ratio equalled 2·35 per 1,000, in Bombay 2·05, and in Madras 1·96. The mortality from bowel complaints was much smaller in all three Presidencies than in 1882. It equalled 12·93 in Bengal, 12·78 in Madras, and 6·79 in Bombay. The most marked reduction occurred in Madras. In the Madras jails the death-rate from these diseases in 1882 had been 20·91 per 1,000; in the year under report, it was reduced to 12·78. As already mentioned, the total death-rate from all causes was greatest in Bombay, although the admission and daily sick-rates were the lowest in this Presidency. The type of sickness prevailing among the Bombay prisoners must therefore have been more severe than in the other two Presidencies. Compared with 1882, the jails of the Bengal and Madras Presidencies show a most satisfactory improvement in the death-rate, the reduction being most marked in the Madras jails, where it amounted to 12·75 per 1,000. In the Bengal jails the diminution equalled 8·28 per 1,000, which also is gratifying. The Bombay jails show an increased mortality, as compared with the preceding year, of nearly 1 per 1,000.

The marginal table shows a very satisfactory diminution in both sickness and deaths among the prisoners of the Bengal Presidency. The results for 1883, on the whole, very nearly approach those of 1877. The admission-rate, especially for 1883, namely, 949, was low, being less even than that for 1877; whilst the daily average sick-rate (32) was reduced by 8 per 1,000 as compared with the preceding year. The mortality from cholera was 2·35. This is, on the whole, a low ratio for the jails of this Presidency. The average cholera mortality for the Bengal Presidency during the years 1859–76 was 6·63; but the fluctuations in the mortality arising from this disease from year to year are so great, that an average result has little meaning. If the period 1859–76 be divided into two equal periods 1859–67 and 1868–76, it will be found that whilst in the former nine-year period the average mortality was 10·77, in the latter it was only 3·28. It is better therefore to compare the death-rate of the year under review with those of other individual years. Since 1865, the lowest mortalities recorded were 1·00 in 1880, 1·10 in 1871, and 2·35 in 1875; whilst the highest were 12·10 in 1866, 6·38 in 1879, and 6·24 in 1869. The very satisfactory decrease in the mortality from bowel complaints from 17·31 in 1882 to 12·93 in 1883 has already been noticed. The average death-rate from these diseases for the period 1859–76 was 21·83, but for the reasons just given, it will be better to compare the results of 1883 with the results of single previous years. In only three other years since 1866 was the ratio lower than it was in 1883, namely, 12·06 in 1868, 12·38 in 1875, and 10·59 in 1877. The highest ratios were recorded during very recent years, namely, 30·65 in 1879 and 28·27 in 1878.

Year.	Average Strength.	Ratio per 1,000.				
		Admissions.	Daily sick.	Deaths from		
				Cholera.	Dysentery and Diarrhœa.	All Causes.
1877–81	69,149	1,145	40	3·99	22·38	55·49
1877 "	63,690	967	30	3·07	10·59	31·88
1878 "	78,116	1,182	41	5·34	28·27	62·35
1879 "	78,801	1,285	46	6·38	30·65	77·90
1880 "	66,751	1,106	40	1·00	21·51	51·12
1881 "	63,478	1,151	41	3·10	17·91	44·42
1882 "	59,489	1,178	40	3·11	17·31	42·56
1883 "	54,982	949	32	2·35	12·93	34·28

The death-rate from all causes in the jails of the Bengal Presidency was 34·28. The average mortality in these jails for the 18 years (1859–76) was 54·24. The ratio for the year under review was among the most favourable on record, better results having been

recorded only in the years 1868 (30·28), 1875 (33·65), and 1877 (31·88). Compared with the high rates which prevailed since 1877, the reduction is most marked.

The following table shows the chief diseases which have caused admissions into hospital since the year 1873. It will be observed, that while the same order of diseases is maintained as in 1882, in every case the ratios of 1883 are lower. Compared with the average results of the ten-year period 1873–82 also, the results of 1883 are very favourable, the admission-rates in only two classes of disease having exceeded the decennial averages, namely, atrophy with anæmia and venereal diseases, and in both cases the excess in 1883 is trifling. The greatest reduction occurred in fevers, and here it equalled 99 per 1,000. Compared with the admission-rate for 1882, the total admission-rate for all the ten chief causes noted in the table was less by 213 per 1,000 and less by 133 per 1,000 than the average of the preceding ten years. A comparison of the total admission-rates from all causes in 1883 with the preceding year and with the ten-year period (1873–82) is also very favourable, showing a reduction of 229 per 1,000 as compared with 1882, and 142 as compared with the ten-year period.

Statement showing the Chief Diseases which have caused Admissions into Hospital in the Jails of Bengal Presidency from 1873 to 1883.

Number.	Diseases.	Decennial Average, 1873–82.	Admitted per 1,000 of Average Strength.									
			1883.	1882.	1881.	1880.	1879.	1878.	1877.	1876.	1875.	1874.	1873.
1	Fevers	488	389	541	528	458	660	556	371	457	398	445	450

10	Spleen diseases	0·35	0·34	0·19	0·22	0·57	0·81	0·23	0·20	0·29	0·77	0·37	0·23
	Total of the Ten	42·91	30·17	38·22	40·13	45·66	71·53	60·63	28·55	34·36	30·03	35·70	38·76
	Total from all Causes	47·36	34·28	42·56	44·42	51·12	77·90	65·35	31·88	37·51	33·65	39·90	43·08

The total death-rate from the ten chief causes of mortality was 30·17 against 38·22 in 1882 and against 42·91, the average of the last ten years. In every disease, with the exception of dropsy, the ratio of 1883 was lower than the average ratio of the ten-year period 1873–82; in the case of dropsy the ratio was equal. The most marked diminution occurred in dysentery and diarrhœa. During the preceding ten years these yielded an average of 18·90, but in 1883

the mortality due to them fell to 12·93. This result is not only satisfactory in comparison with the ten-year average, but also when compared with individual years, for it is the lowest which has been recorded since 1859, with the exception of 1875 and 1877, when it was 12·38 and 10·59. The next largest diminution occurred in fevers, the mortality from them was 2·38, less by 2·91 than the ten years' average. With the exception of the years 1876 and 1877, when the mortality was 2·36 and 1·97, the death-rate for 1883 is lower than for any year since 1865. There was also a diminution in the mortality from respiratory diseases as compared with recent years; but the reduction in them is not so marked as in bowel complaints and fevers. They caused a death-rate of 6·00 against an average of 7·18 for the ten-year period. The average death-rate of the last ten years has been raised considerably by the high ratios of recent years. Moreover, the average of the ten-year period (1863–72) was only about one-half that of the previous ten-year period; and when individual years are compared, it appears that the deaths caused by respiratory diseases in 1883 were in higher proportion than in 18 out of the 24 years since 1859.

Of the various geographical groups into which the Bengal Presidency has been divided, sickness was least prevalent in Agra and Central India and in the Gangetic Provinces with Oudh, and most prevalent in Lower Bengal and Assam. The same general result was observed in 1882. In order of unhealthiness the several groups arrange themselves as follows: Bengal with Assam, Central Provinces, Punjab, Rohilcund and Meerut, Gangetic Provinces with Oudh, and Agra with Central India. The admission-rate in Lower Bengal with Assam was nearly three times as high as it was in Agra and Central India, and more than twice as high as it was in the Gangetic Provinces with Oudh and in Rohilcund with Meerut.

Statement showing Sickness and Mortality amongst the Prisoners of the Bengal Presidency (arranged in groups in accordance with their geographical positions) from 1877–81, 1882 *and* 1883.

Groups.		Average Strength.	Ratio per 1,000.					
			Admissions into Hospital.	Daily Sick.	Deaths from			Difference between Average Mortality and year's Mortality.
					Cholera.	Dysentery and Diarrhœa.	All Causes.	
I.—Lower Bengal and Assam	1877–81	14,788	1,519	50	7·43	31·63	67·50	−14·98
	1882	13,327	1,693	54	8·25	25·44	59·95	
	1883	12,414	1,630	53	4·03	22·64	52·52	
II.—Gangetic Provinces and Oudh	1877–81	22,769	695	25	3·21	13·98	33·29	−7·53
	1882	13,515	724	28	3·19	14·36	32·70	
	1883	16,846	616	23	3·32	8·67	25·76	
III.—Central Provinces (excluding Jubbulpore and Saugor)	1877–81	3,002	983	36	11·39	26·11	69·38	+16·66
	1882	2,833	1,106	48	4·24	49·42	99·66	
	1883	2,609	1,003	41	4·22	60·56	88·54	
IV.—Agra and Central India	1877–81	5,338	1,063	49	2·89	17·16	51·33	−29·77
	1882	4,513	763	28	0·89	6·65	27·92	
	1883	4,359	556	21	2·75	6·19	21·56	
V.—Rohilcund and Meerut	1877–81	9,972	935	40	0·35	15·36	37·69	−19·33
	1882	7,187	1,007	38	—	7·65	25·46	
	1883	6,627	753	31	—	3·62	18·26	
VI.—Punjab	1877–81	14,180	1,674	51	2·38	31·64	88·13	−59·02
	1882	13,115	1,546	45	—	15·25	41·63	
	1883	12,128	951	27	—	6·18	29·11	

The daily sick-rate in Bengal and Assam was also high—53 per 1,000. Next comes the Central Provinces with 41 per 1,000, a ratio somewhat lower than that of 1882, but higher than the average of the five-year period 1877–81. Third comes Rohilcund and Meerut with 31 per 1,000, and then the Punjab with 27, the Gangetic Provinces with 23, and lastly Agra with Central India with a minimum of 21. The mortality from all causes as compared with the averages for the period 1877–81 fell in every group, with the single exception of the

Central Provinces, where the death-rate was 18·66 per 1,000 greater than the five-year average. A similarly unsatisfactory result was noted in the report for 1882. The highest mortality, 88·54 per 1,000, occurred in the Central Provinces; and next in order of high mortality come Bengal with Assam, 52·52, Punjab, 29·11, Gangetic Provinces with Oudh, 25·76, Agra and Central India, 21·56, and Rohilcund and Meerut, 18·26. In the last column of the statement given above, the differences between the death-rate for 1883 and the average mortality for the five-year period 1877–81 are given. It will be observed that the greatest reduction occurred in the Punjab, the next in Agra and Central India, Meerut and Rohilcund, Bengal and Gangetic Provinces with Oudh. It will be noticed that the death-rate in only the first and third groups exceeded the average death-rate from all causes for the whole Presidency. The mortality from cholera was much the same in the 1st, 2nd, and 3rd groups—4·03, 3·32 and 4·22. In the Agra and Central India group it was 2·75; no deaths from this disease occurred in the Rohilcund and Meerut and Punjab groups. The jails of these two groups enjoyed a similar immunity from cholera during the preceding year, 1882. Dysentery and diarrhœa caused by far the largest mortality in the Central Provinces group—60·56 per 1,000 against 49·42 in 1882, and 26·11 the average of the preceding five years. In all the other groups there was a satisfactory reduction in the death-rates from dysentery and diarrhœa.

Some improvement took place in the health of the prisoners in Lower Bengal as compared with former years. This is clearly shown in the marginal table. The admission-rate, 1,498, was less than it had been in any of the four preceding years, but was nevertheless higher than the average of the five years, 1877–81. The daily average sick ratio, 50, is also lower than that of the preceding year by 4 per 1,000, but greater than the five years average by 2 per 1,000. Sickness was thus but little less prevalent than it had been during the four preceding years, but the mortality was much less. The total death-rate was 52·21, against 69·21 in 1882 and 70·05 the average of the preceding five years. The mortality from cholera (4·27) was less than half that of the preceding year and was below the results of most previous years. The average of cholera mortality during the 18 years 1859–76 was 13·31. The comparison, however, is not quite exact, for in these years Assam was included in Bengal. A marked reduction also occurred in the death-rate from bowel complaints, which equalled 23·44. In only eight former years since 1859 was the result more favourable, in two of which, however, the difference is only nominal. The admission and death-rates from fevers (5·46 and 3·15) and bowel complaints (4·77 and 23·44) were lower than in any of the previous seven years. The average fever mortality for the period 1859–76 was 4·12.

Year.	Average Strength.	Ratio per 1,000.				
		Admissions.	Daily Sick.	Deaths from		
				Cholera.	Dysentery and Diarrhœa.	All Causes.
1877–81	17,317	1,457	48	9·34	32·94	70·05
1877	16,862	1,276	39	8·29	36·98	49·26
1878	17,712	1,291	43	21·85	31·60	70·89
1879	17,771	1,573	51	18·91	45·92	97·37
1880	17,218	1,560	53	1·60	33·74	64·94
1881	16,014	1,504	53	5·37	34·72	67·13
1882	15,530	1,948	54	9·28	32·36	69·23
1883	14,298	1,498	50	4·27	23·44	52·21

The results here given for the years 1880 and 1881 differ somewhat from those given in the same table in former Annual Reports, in which they were for Bengal and Assam combined. Those now given are for Bengal alone.

If the jails of Lower Bengal be judged by admissions into hospital, sickness prevailed most in the Khulna Jail. There the admission-rate was 3,983 per 1,000 and the daily average sick-rate 86. But the mortality from all causes was only 17·24 per 1,000. This jail was opened during the year; the number of prisoners was small, and the accommodation of a temporary nature. The next highest admission-rate occurred in the Russa Jail, 3,581. The Furreedpore Jail is the only other with an admission-rate exceeding 3,000 per 1,000. During the preceding year the admission-rate in only one jail, Moorshedabad, exceeded 3,000. Of the 47 jails of this province 3 recorded admission-rates over 3,000, 10 over 2,000, and 28 over 1,000 per 1,000. Only 3 of the 47 jails show a smaller admission-rate than 500. The highest death-rates were recorded in the Julpigoree (299·15), Ranchee (187·50), Rungpur (183·33), Bogra (115·04), Kishnaghur (107·95) and Midnapur (102·89) jails. In Julpigoree the average strength was 117, and the above death-rate was the result of 35 deaths, of which 19 were due to cholera, 10 to dysentery and diarrhœa, and 6 to respiratory diseases. In Ranchee the average strength was 160; 30 deaths took place, of which 20 were due to dysentery and diarrhœa. In Rungpur the average strength was 240 and 44 deaths occurred, of which 19 were due to dysentery and diarrhœa and 13 to phthisis. In Bogra the strength was 118 and deaths 13: 7 of these were due to dysentery and diarrhœa. In Kishnaghur the strength was 176, and the number of deaths 19; 8 of these were due to dysentery and diarrhœa. Midnapur is a large jail with an average strength of 797; 82 deaths occurred, no less than 54 of which were due to bowel complaints. No deaths took place in the Darjeeling, Noakholly, and Balasore Jails; but these are small jails, containing few prisoners. The lowest mortalities were recorded in the Bhagalpur Central Jail (12·78), Maldah (14·08), Chybassa (15·87), Khulna (17·24), Buxar (18·40), and Cuttack (19·69). Of these jails the

Bhagalpur Central Jail and the Buxar Jail are large; the former with an average strength of 1,017, the latter of 924. Nearly half the mortality of the Bhagalpur Jail was due to diseases of the lungs, whilst nearly one-half the deaths in the Buxar Jail was due to dysentery and diarrhœa. The largest number of cases of cholera occurred in Julpigoree: 23 cases with 19 deaths. In Alipur there were 17 cases with 8 deaths, in Patna 12 with 6 deaths, Buxar 13 with 2 deaths. The largest proportion of admissions for dysentery and diarrhœa took place in Khulna (1,328); Julpigoree, (1,205); Bogra (1,274); 20 other jails showed an admission-rate under this head of above 500 per 1,000; 23·44 of the total mortality, namely, 52·21, was due to these diseases.

The statistics of the jails of the North-Western Provinces and Oudh show a great improvement as compared with those of the five previous years. The admission-rate, 563 per 1,000, was considerably below that of 1882 (724). The daily average sick fell from 29 in 1882 to 23 per 1,000. The total mortality from all causes was 19·76, a ratio but little exceeding that of the year 1877 (17·54) which was the lowest recorded. Excluding cholera, the death-rate of 1883 still remains the second lowest on record. The death-rate from cholera was 2·16, a high ratio for these Provinces when compared with recent years. The average mortality from cholera during 1859–76 was 4·11, but this average was much raised by the exceptionally high rates recorded in 1860 (15·98), in 1861 (27·36), and in 1863 (9·76). The average death-rate from cholera for the nine years, 1868–76, was only 1·45. The mortality from dysentery and diarrhœa was 4·32, the lowest on record since 1859. This result was most nearly approached in former years, in 1877, when it was 4·65. The highest death-rates recorded from these diseases were 51·81 in 1859 and 44·94 in 1861.

Of the 53 jails in the North-Western Provinces and Oudh, 12 show a higher admission-rate than 1,000 per 1,000. Unao (1,195), Allahabad District Jail (1,128), Banda (1,073), Mirzapur (1,057), Bahraich (1,044), Muttra (1,112), Etah (1,250), Shahjahanpur (2,034), Budaon (1,175), Saharanpur (1,258), Almora (1,008), and Muzaffarnagar (1,412). Twenty-two others show above 500 per 1,000, leaving 19 or nearly 36 per cent. of the 53 jails with an admission-rate below 500. The highest death-rates were recorded in the following jails: Gorakhpur (146·62), Dehra Dun (127·27), Banda (64·52), Orai (60·15), Mirzapur (56·70), and Almorah (56·45). In all the others the mortality was below 50 per 1,000. In Gorakhpur, out of an average strength of 607, 89 deaths took place, of which 38 were due to cholera and 25 to dysentery and diarrhœa. At Banda, out of an average strength of 248, 16 deaths occurred, of which 7 were due to dysentery and diarrhœa. Cholera attacked only the Gorakhpur, Muttra, and Agra Jails. At Gorakhpur, where the outbreak was most severe, there were 57 cases in all, and of these 38 proved fatal; 54 of the cases took place in September, and the remaining 3 in October. In these Provinces only 4·32 of the total mortality (19·76) was due to dysentery and diarrhœa. Respiratory diseases gave rise to the highest death-rate, 4·66. They were most prevalent in Mirzapur (196 admissions per 1,000), Almora (121), Etah (97), Muzaffarnagar (87), and Orai (83).

The statistics of the Punjab jails are also very favourable. The admissions equalled 951 per 1,000, a ratio considerably smaller than that of recent years. Judged by this test, there was less sickness in only 1866 (893), 1868 (799), and 1871 (825). The daily average sick-rate was 27 per 1,000, which is also below the average since 1865. The death-rate from all causes was 29·11 per 1,000, a reduction of 12·52 upon that of the preceding year, when it equalled 41·63, and a reduction of 20·46 upon the average mortality of the last 20 years, which was 49·57. The average total mortality from all causes for the period 1859–76 was 38·98. During the last 20 years better results than these were recorded only in the years 1871 (27·19), 1868 (12·39), 1867 (24·66), and 1866 (18·32). During 1883 cholera was again entirely absent as it had been in 1882. The average death-rate for cholera during the last 20 years was 1·16 per 1,000. The mortality from bowel complaints in 1883 was 6·18, or less than half that of the preceding year or of the average of the last 20 years, which was 14·09. It was still, however, higher than it had been in several single former years since 1859,—*e.g.*, in 1865 it was 4·77; in 1866, 2·43; in 1867, 5·62; in 1868, 3·08; and in 1874, 5·88.

In the Punjab, as in the North-Western Provinces, respiratory diseases caused the greatest mortality or 9·73 per 1,000. Next came dysentery and diarrhœa with 6·18. The mortality arising from respiratory diseases continued to be higher than usual. During the years 1859–67 the average was 2·81: in the succeeding nine-year period, 1868–76, it rose to 8·00, whilst since that time, namely, 1877–82, the average has been 16·66—a large increase on former years. The highest mortality, 21·59, was recorded in 1879, but in the years preceding and succeeding that year it was nearly as high, having been 20·42 in 1878 and 20·87 in 1880. Of the 35 jails in this province, 2 recorded an admission-rate for all diseases above 2,000, namely, Abbottabad and Dera Ismail Khan. The former is a small jail with an average

strength of only 77 prisoners: the latter had an average strength of 496. Ten other jails recorded ratios above 1,000 per 1,000; in 8 it was below 500. During 1882, 8 jails recorded ratios above 2,000 and only 5 below 500. In Dera Ismail Khan the chief diseases causing admission were intermittent fevers (1,617), dysentery and diarrhœa (121), and respiratory diseases (107). The greatest mortality occurred in the following jails: Lahore Central Jail (65·99), Mooltan District Jail (47·13), Dera Ismail Khan (46·37), and Mooltan Central Jail 40·85. The Simla Jail also shows a death-rate of 50, but the strength was so small that this represents only one death during the year. In the Lahore Central Jail 123 deaths took place, 45 of which were due to dysentery and diarrhœa, 23 to respiratory diseases, and 15 to fevers. The death-rate in this jail, though again the highest among the Punjab jails, is still considerably lower than it was in 1882 (113·22). In the Mooltan District Jail 32 deaths occurred, 15 due to respiratory diseases and 9 to fevers; whilst in the Central Jail 25 deaths occurred, 18 being due to respiratory diseases, and only one to fever. The Rupar Jail was merged during the year into the Mooltan Central Jail. In Dera Ismail Khan 23 deaths occurred, 14 from respiratory diseases and 5 from dysentery and diarrhœa. Eight jails showed a higher mortality than the average of the province, namely, Ferozepore, Amritsar, Lahore Central Jail, Lahore District Jail, Mooltan Central Jail, Mooltan District Jail, and Dera Ismail Khan.

In the report for 1882 very unfavourable results in the jails of the Central Provinces were noted. Those for 1883 are but little better. The admission and daily sick-rates, 919 and 36, were somewhat less than they were in the preceding year, 966 and 41; but the death-rate from all causes was practically the same, namely, 70·97 against 71·05 in 1882. The death-rate for the last 20 years averaged 55·64, so that the mortality of 1883 exceeds this average by 15·33 per 1,000. This death-rate of 1883 has only been exceeded in six former years since 1859, namely in 1859 (72·81), 1863 (72·27), 1865 (125·77), 1866 (72·25), 1878 (118·11) and 1882 (71·05). The proportion of mortality due to cholera was practically the same as it was in 1882, namely, 2·84 against 2·91. These ratios are much below the average for the past 20 years, which is 7·31. The high total mortality was mainly due to bowel complaints, and this chiefly in the Nagpur and Raipur Jails. They contributed no less than 46·71 per 1,000 of the total. The mortality from bowel complaints is the highest since 1859, and exceeds the average of the last 20 years by 24·18 per 1,000. The mortality during 1882 was attributed to Kalahundi prisoners.

Of the 19 jails in the Central Provinces 4 record higher admission-rates than 1,000, viz., Sambalpur (1,260), Raipur (1,315), Seoni (1,458), Nagpur (1,051). In these dysentery and diarrhœa caused the largest number of admissions, excepting in the small jail at Seoni, where fevers were the most prevalent form of sickness. The highest mortality was in the Raipur (143·40), Nagpur (108·49), Sambalpur (62·99), Chhindwara (62·50), and Nimar (50·00) jails. In the Raipur and Nagpur Jails, the only large jails included in the above, the chief causes of death were dysentery and diarrhœa. In the Raipur Jail, of the 113 deaths which occurred, 87 were due to these causes; and in the Nagpur Jail 57 of the 92 deaths were due to the same. In the Sambalpur Jail 8 deaths occurred, of which 6 were due to bowel complaints. At Jubbulpore, the admission-rate was 778 and total death-rate 38·66. Cholera appeared in the Nagpur and Bhandara Jails: in the former there were 13 cases with 10 deaths, and in the latter 2 cases with 1 death.

In Berar sickness was somewhat greater than it had been in the preceding year. The admission-rate was 558 against 449 in 1882, and the daily average sick-rate 14 against 12. These results, though less favourable than those of 1882, are still very favourable when compared with years preceding 1882. The increase in sickness was almost entirely due to the greater prevalence of malarial fevers in the Amraoti Jail. The mortality from all causes was almost identical with that of the preceding year, 8·49 against 8·50 in 1882. The statistics of these jails are available since 1870, and the average mortality from that time to 1882 is 31·39. The ratio for the year under review was therefore 3½ times less than this average. The ratios of 1882 and 1883 are by far the lowest on record, the next lowest having been 15·58 during 1877. The highest ratio recorded was 75·14 in 1878. Cholera was exceptionally prevalent in that year and caused 14·64 per 1,000 of this total ratio. During 1883, as in the preceding year, no deaths occurred from cholera. The mortality due to bowel complaints was 1·89; in 1882 there was no death under this head. The average death-rate from these diseases since 1870 was 6·81. The highest ratio on record was 17·56 in 1878.

In this province there are only six jails. The highest admission-rate was recorded in the Ellichpur Jail, a small jail with an average strength of only 59 prisoners. The largest jails are those at Amraoti and Akola. The admission-rates in these were respectively 722 and 218. The highest admission-rates were due to fevers (292 per 1,000), abcesses and ulcers

(56), and dysentery and diarrhœa (44). Three of the jails recorded deaths: Ellichpur and Amraoti 2 deaths each, and Akola 5.

The results in the Burma jails were much the same as in 1882. The admission-rate continued high, 1,159 against 1,168 in 1882; the death-rate, 28·94, though slightly greater than that of 1882, was considerably less than the average since 1869 (37·75). During this period the highest death-rates were recorded in the years 1878 (57·71), 1877 (56·76), and 1869 (51·9), and the lowest in 1875 (23·5), and 1880 (24·89). Of the total mortality of 1883, 7·96 were due to cholera. This is somewhat less than the average for the years since 1869 (8·78). Considerable fluctuations occur as usual in the death-rates from cholera in these jails. In 1871 there was an entire absence of such mortality, whilst in 1878 it equalled 25·27. From bowel complaints the death-rate was 7·96, which, though a little greater than that of the preceding year, is yet below the average of past years (9·53).

Of the 12 jails in British Burma four, namely, Akyab, Rangoon, Shwegyeen, and Moulmein, record admission-rates above 1,000; in four it was below 500 per 1,000. In Akyab, Shwegyeen, and Moulmein, the rate was higher than in 1882, but in Rangoon it was less. The chief causes of admission in these jails were fevers, injuries, and dysentery and diarrhœa. The highest death-rates occurred in Kyaukpyu (169·23) and Akyab (132·77). In both these jails the mortality was greatly raised by deaths from cholera. In the former jail 115·38 per 1,000 of the total mortality was due to this cause, and in the latter 73·45. No cholera deaths occurred in any of the other jails.

Sickness and mortality were greater in the jails of Assam than in 1882. The increased sickness is attributed to increased unhealthiness generally throughout the Province. The admission-rate, 2,125, and the daily sick-rate, 56, are the highest since 1877, when Assam was separated from Lower Bengal. Judged by these rates sickness was more prevalent in the jails of Assam than in any other Province of India, the next highest admission-rates, 1,498 and 1,454, having been recorded in Bengal and the Convict Settlement, Andamans. The total mortality in Assam was 43·12 against 33·08 in 1882. The mortality from cholera was 5·80 or nearly equal to the unfavourable average of the five years 1877-81, which was 6·67. The disease was present in four of the five jails, Gauhati alone having escaped entirely. The mortality from bowel complaints (16·58) also somewhat exceeded the ratio of 1882, which was 15·38. This mortality is, however, considerably less than that of the jails of Lower Bengal, 28·44, and than the average mortality since 1877 (24·21). Since 1877 the highest mortality from bowel complaints was 34·32 in 1879. In Assam as in Bengal the prevalence of dysentery and diarrhœa contributes largely to sickness and death. Of the total admission-rate (2,125) 517 were due to these diseases.

Although the admission and daily sick-rates in the jails of Madras show greater sickness than in the three preceding years, yet the mortality was considerably less. This was mainly due to the reduction in the mortality of the Trichinopoly Central Jail. The admission-rate was 861 and the daily average sick 32 against 795 and 29 respectively in 1882. The mortality from all causes fell considerably: it was 29·87 against 42·62 in the preceding year, and 63·98 the average death-rate of the 20 preceding years. The highest death-rates recorded since 1868 were 176·01 in 1877, 126·3 in 1865, and 125·92 in 1878; the lowest, 17·9, in 1871, and 22·2 in 1872. Cholera was less prevalent than usual, and yielded a mortality of 1·96, which is considerably below the average death-rate of the past 20 years, namely, 7·78. A very great reduction in bowel complaints is also to be noticed. The deaths from this cause equalled 12·78 against 20·91 in 1882, and an average of 25·72 for the 20 previous years. The mortality from these diseases during the last 20 years has ranged between a minimum of 5·2 in 1871 and a maximum of 85·15 in 1877.

Of the 30 jails in the Madras Presidency, 11 show admission-rates above 1,000, and 6 below 500. The chief causes of admission were fevers, abscesses and ulcers, and dysentery and diarrhœa. The greatest sickness occurred in the Cuddapah (1,992) Rajamundry Central (1,716), Kurnool (1,608), and Chingleput (1,562) Jails. All these, however, with the exception of the Rajamundry Central Jail, are small jails. In the Rajamundry Central Jail fevers gave rise to 1,122 per 1,000 of the total admission-rate. The highest death-rates were recorded in the following jails: Tanjore (86·21), Bellary (74·30), and Cuddalore (73·86). In Tanjore 10 deaths took place, 8 of which were due to dysentery and diarrhœa; in Bellary 24 deaths, of which 10 were due to the same cause, 4 to respiratory diseases, and 4 to anæmia and debility. In Cuddalore there were 13 deaths, 9 due to cholera and 4 to dysentery and diarrhœa. In the Tranquebar, Madras Debtors', Nellore and Guntoor Jails, there were no deaths. In the Trichinopoly Central Jail, which, in 1882, suffered the high mortality of 164·77, a total death-rate of 55·16 was recorded, 3·56 of which was due to cholera. In this jail there were 31 deaths in all against 145 in 1882; 15 of them were due

to dysentery and diarrhœa. Cholera appeared in seven of the jails; there were in all 34 cases with 15 deaths. It was most severe in the Cuddalore Jail, where of the 21 attacked 9 died.

Among the prisoners of the Bombay Presidency there was a considerable reduction in the admission-rate. This was 734 as compared with 843 in 1882, and 1,158 the average of the five-year period, 1877–81. But the daily sick and total mortality ratios were somewhat greater than in 1882. The daily sick-rate rose from 26 in 1882 to 27, and the total mortality from 33·35 to 34·33. Although the total mortality was greater than that of the preceding year by nearly 1 per 1,000, it was yet considerably lower than the average for the 18 previous years, for which statistics are available, and which equalled 47·15. This average is made up of ratios varying from a minimum of 21·9 in 1876 to a maximum of 118·27 in 1878. The death-rates from 1877 to 1881 were exceptionally high, the average being 76·83. The average for the five years immediately preceding was 26·60. The results of the last two years are satisfactory, as showing a tendency to revert to the more favourable results of former years. Cholera prevailed more extensively in 1883 than it did in 1882, the deaths from it having equalled 2·05 in 1883 and 1·13 in 1882. Deducting these from the total of each year the result of 1883 is almost the same as that of 1882, the ratios standing 32·22 in 1882 and 32·28 in 1883. The mortality from dysentery was 6·79. This is somewhat less than it was in 1882, and about half the average for the previous 18 years, which is 13·77. This last average is made up of ratios varying from a minimum of 4·3 in 1868 to a maximum of 44·14 in 1878.

In the Bombay Presidency there are 32 jails. Of these only one, the small jail at Sawantwari, recorded an admission-rate higher than 2,000, and 7 above 1,000. Of these seven the Mhasvad Gang is the only large jail; it had an average strength of 579. The admission and daily sick-rates for this jail were 1,100 and 40. The chief causes of admission were fevers, dysentery and diarrhœa, and respiratory diseases. The next largest of the seven jails is that at Poona. The admission and daily sick-rates in this jail were 1,284 and 37, and the same diseases which gave rise to them in the Mhasvad Gang prevailed here also. In the Bombay jails, as a whole, fevers gave rise to the largest number of admissions, and next in order come dysentery and diarrhœa, abscesses, and ulcers, and respiratory diseases. Only seven jails recorded admission-rates below 500. The highest total mortality occurred in the Shikarpore Jail, 100·61 per 1,000, and this large mortality does not include any deaths from cholera. Sixty-six deaths occurred, and of these 15 were due to respiratory diseases, 13 to fevers, 8 to apoplexy, and 5 to dysentery and diarrhœa. The next highest mortality occurred in the Nara Jail, viz., 67·66, and here, too, there was no cholera. Of the 41 deaths registered in this jail, 16 were due to respiratory diseases and 14 to fevers; in five jails no deaths were recorded, and in 10 less than 25 per 1,000. Cholera attacked 9 of the jails, but in 4 of them only single cases occurred. The largest number of cases occurred in the Mhasvad Gang, namely, 11, and of these 6 died. In the Dhulia Jail 6 cases occurred with 4 deaths, and in the Yerrowda Jail, the largest in the Presidency, 5 cases with 2 deaths.

The results among the convicts in the Andamans are the most favourable on record. The admission-rate, 1,454, was considerably lower than it had been during any of the four previous years. The daily sick ratio was 67 against 80 in 1882 and 95, the average of the years 1877–81. The total death-rate, 19·63, was about one-half that of the preceding year, which was itself a favourable result as compared with the majority of the years preceding it. The death-rate from bowel complaints was notably reduced and was only 2·87. These favourable results are doubtless due, in a very large measure, to the careful observance of the measures which were noted in the Annual Report for 1882. Among the most important of these measures is gradual acclimatization and the avoidance of exposure on reclamation works during the rainy season. In connexion with this last point the Principal Medical Officer reports that "during the year (1883) in-door work all through the rainy season was "provided for as many prisoners as was found possible." A satisfactory feature in the medical history of the year was the freedom from gangrene, which formerly caused many admissions. During the year only two cases occurred. This is attributed to the careful attention paid to all cases of wounds and injuries, however trivial.

General Population.

Progress made in registration of vital statistics.

In Assam considerable progress was made in the registration of vital statistics of late years. The results are still imperfect, but the marked improvement is very satisfactory. The results in the North-Western Provinces with Oudh and Punjab also indicate that decided advance is being made. In both of them the birth and death registration extend over the whole province; in Assam the only parts excluded are some remote hill tracts. In the Central Provinces and Berar, registration has for some years been general, and the system has become established on a fair footing. On the other hand, the results obtained in Bengal and Burma are very imperfect. Registration in both provinces is restricted, and yet the records are less accurate than in other provinces where it is general. In the Madras Presidency, registration of births and deaths is not confined to selected areas; but there are still great imperfections. In Bombay also registration is general, and on the whole is fairly well performed. In the Sind Division, however, it is still backward, and the results of the Presidency as a whole are vitiated from this cause.

Analysis of vital statistics of provinces.

Excluding Mysore and Coorg, the highest birth-rate was recorded in the North-Western Provinces with Oudh and the lowest in Bengal; the rates in the Central Provinces and Berar very nearly approached the ratio of the North-Western Provinces; they were all above 40 per 1,000. The low birth-rate of 22·08 recorded in the municipalities of Bengal is evidently much below the truth. The greatest excess of male over female births was noted in the Punjab, this excess having been 15·14 per cent.; the smallest excess was recorded in Madras, where it equalled only 4·6 per cent. The highest death-rate occurred in Berar, 51·3 per 1,000, and the lowest in Burma, 14·67. The excess of male over female deaths was greatest in Bengal, where it equalled 18 per cent. In the North-Western Provinces with Oudh and in Assam the excess was nearly 16 per cent.; in Madras it was only 5·7 per cent. In all provinces the urban mortality exceeded the rural mortality. The excess was greatest in Burma, were it equalled 12·26 per 1,000; in Bengal and the North-Western Provinces with Oudh it was over 8; in the Central Provinces it was 1·08, and in Berar only 1·90.

In Bengal Proper some steps were taken with a view to securing greater accuracy in the registration of vital statistics; but the results do not show any great advance. The average birth-rate in 46 selected areas in which alone births are registered was 22·08 against 22·65 in 1882. The ratio varied from 6·40 at Darjeeling to 49·17 at Jamalpur in Monghyr. In 30 out of the 46 towns, the birth-rate was less than the death-rate. The death-rate of the province was 18·32 against 20·41 in the preceding year; but this total ratio is a mean of ratios varying from 9·93 in the Monghyr district to 36·07 in Nuddea. In only five districts did the mortality exceed 25 per 1,000. The mortality in rural circles was 18·49 and in towns 27·28. This last ratio is a mean of ratios varying from 9·56 in Sudharam to 46·97 in Gya. In all cases the mortality was less than in the preceding year, but the reduction was most marked in the case of small-pox. This is the more remarkable when taken in connexion with increased prevalence of this disease in India as a whole, as is more particularly indicated in the following section of this report. The last six months of the year were as usual the most unhealthy. Of these November and December were the worst. There was less sickness and mortality among European seamen in the port of Calcutta than in 1882. Both the admission-rate and the death-rate (excluding cholera) were lower than they had been in any year since 1879. Cholera was less fatal than in either of the two preceding years, but was still twice as severe as in 1886. The health of the Native floating population was much the same as it had been during the previous year. Cholera was the chief cause of death.

In the North-Western Provinces with Oudh, the year, owing to a light rainfall, was remarkable for the dryness of its autumn months. It was a year of plenty and cheapness of food, accompanied by improved health and prosperity of the people. The average birth-rate for the province was 40·84 per 1,000, the highest on record since 1879, when registration was commenced, and the highest in any of the provinces of India. There were great variations in the birth-rates of the various districts of which it is a mean. These variations range from 58·24 (Lalitpur) to 20·39 (Dehra Dun). In all districts, except the Terai, where exceptional disturbing influences exist, the birth-rate exceeded the death-rate. In the province as a whole, for every 100 girls, 111·81 boys were born. The total death-rate was 27·57 per 1,000, which was less than in any year since 1877. The rates in the several districts varied from 17·49 to 48·33 per 1,000. The excess of male over female deaths was on an average 15·88 per cent. The rural mortality was 27·65, and the urban mortality 35·32. The largest number of deaths occurred in May, and the smallest in October. Cholera accounted for but a small proportion of the deaths, whilst small-pox contributed an unusually large proportion of them.

Registration of births extends over the whole province of the Punjab. The total birth-rate was 39·0. This ratio is probably not much under-estimated, as it corresponds closely with the ratios of municipalities, where registration is fairly accurate. In the 49 principal towns of the province, the average birth-rate was 41 per 1,000. Of the provincial ratio, 20·87 per 1,000 represent male births, and 18·13 female; the number of boys born exceeding the number of girls by 15·14 per cent. The total death-rate of the province was 25 per 1,000 against 27 in 1882. This decrease is attributed to the healthiness of the year, but it is doubtless due also in part to imperfect registration. In the principal towns of the province the average death-rate was 30 per 1,000. Throughout the province, for every 100 female deaths there were 116·84 male deaths. The death-rate was greatest during the first two and the last two months of the year. The mortality from cholera was very small; that from small-pox was nearly double what it had been during the previous year. The mortality from fevers and bowel complaints was less than it had been in any year since 1877.

The area under registration in the Central Provinces was increased and the total population included was raised from 8,802,040 to 8,817,185. Food was abundant and cheap, and in the absence of any unusual prevalence of disease an increased birth-rate over that of the previous year might have been expected. But the total number of births registered—namely, 357,864—fell short of the number of the preceding year by 9,464. The decrease in the birth-rate extended to 11 out of 20 districts; in only four districts there was some increase, and in the remaining five the ratio was the same as in the year previous. The provincial birth-rate, which was 40·59, is a mean of district ratios varying from 34·15 to 54·29. Male births preponderated over female births by 7·61 per cent. The total death-rate was 34·56 per 1,000, a ratio almost identical with that of 1879, but greater than that of any of the intervening years. 109 males died for every 100 females. The rural mortality was 34·43 per 1,000, and the urban 35·56. All the chief diseases contributed a larger proportion of deaths than in any of the preceding years.

New rules for the registration of vital statistics in Berar were in force during the year. The total birth-rate was 40·3 per 1,000, or less by 1·7 per 1,000 than the ratio of 1882. The decrease was probably due to the greater unhealthiness of the year. Registration in some municipalities was still very backward,—*e.g.*, in Khamgaon, where the birth-rate was only 9·5 per 1,000. The birth ratios of districts were not so divergent as is generally observable in other provinces, ranging as they did from 37·8 to 43·2. Male births exceeded female births by 6·5 per cent. The total number of deaths registered was 135,081, or 57,867 more than in the previous year. The total death ratio for the province was 51·3, a mean of district ratios varying from 39·8 to 65·7. This mortality means a loss of a little over one-nineteenth part of the whole population. Mortality was heavy from all the usual chief diseases, but that from cholera (10·6 per 1,000) was specially severe. The mortuary statistics of individual districts show that although the causes which gave rise to this high death-rate operated to a great extent throughout the province, they did not operate with equal intensity everywhere, for while in Basim the mortality was nearly double, and in Ellichpur more than double that of 1883, in the Wun district the excess was only 19 per 1,000. The rural and urban mortality did not vary much: it was 51·3 in rural circles and 53·2 in towns. One hundred and seven males died for every 100 females. The highest mortality occurred in August; nearly one-half of the total deaths of the year took place in July, August, and September. The Sanitary Commissioner is of opinion that the heavy mortality of the province, and particularly that due to cholera, was influenced largely by the heavy rainfall of the year.

During the year a further reduction was made in the area under registration in British Burma. It was found that reports from certain districts were so imperfect as to vitiate the results as a whole. A revised scheme was under consideration, the adoption of which it is hoped will result in more accurate statistics. The total birth-rate for the province was 22·02. This is manifestly much below the truth; it is, moreover, a mean of variations ranging from 16·60 to 31·65. The births of boys exceeded those of girls by 6 per cent. There were great variations also in the death-rates of the several districts, which ranged from 9·22 to 21·42. The total mortality for the province was 14·67. Deaths of males greatly exceeded those of females; 127 males died for every 100 females. The death ratio for the urban population was nearly double that of the rural population—25·50 against 13·24. The latter ratio is evidently under the truth.

In Assam, registration which had hitherto been confined to the six districts of the Brahmaputra Valley, was extended during the year to the two remaining districts of the Surma Valley as well as to portions of the Khasi Hills. The population thus added embraced 4,527,934 persons out of a total of 4,881,426 in the entire province. Compulsory registration was introduced in the latter half of 1882, and was in force in all the 21 towns of the province throughout the year 1883. But, although registration in Assam has made decided

progress of late years, the results of 1883 did not indicate any further advance. The birth-rate of the province, which in 1882 was 24·83 per 1,000 fell in 1883 to 23·91. All districts, except Goalpara and Sylhet, shared in the decrease. The birth of males exceeded the birth of females by nearly 10 per cent. The total death-rate was 27·14 against 25·92 in 1882. The extremes in districts varied from 16·27 to 41·89. Deaths were most numerous in May and June. In towns the mortality was at the rate of 36·07, and in rural circles at the rate of 27·08 per 1,000. Male deaths exceeded the female deaths by 2·45 per 1,000. For every 100 female deaths, there were 116 male deaths. Cholera gave rise to a smaller mortality than in 1882, but the ratio of deaths from it was still unusually high. Small-pox gave rise to a high rate of mortality, although, as above remarked, it was lower than usual in the Province of Bengal.

The census results of 1881 have been utilised for the first time in computing the statistics of 1883 in the Madras Presidency. They show an increase of 86,370 over the total population in the preceding census. The total number of births registered was 791,774, which was more than in any year since 1869, when registration was commenced. These births yielded an annual rate of 27·7 per 1,000. In 18 of the 22 districts of the Presidency the birth ratio was between 20 and 40·9, and in only one district—Malabar—the death-rate exceeded the birth-rate. For every 100 girls born there were 104·6 boys. The total death-rate was 19·0 per 1,000 against 16·2 in both 1882 and 1881. Both these ratios are manifestly under the truth. In 11 of 22 districts the death-rate was below the average of the Presidency, and in the rest it varied from 19·4 to 38·6. With the exception of three districts, the male deaths everywhere exceeded the female deaths, the average excess for the Presidency being 5·7 per cent. In urban circles the mortality was 24·9 per 1,000, and in rural circles 18·6. The largest number of deaths occurred in December, and the smallest number in April. The death ratios from all the chief causes of death were greater than in 1882. Cholera and small-pox were unusually prevalent and fatal as compared with recent years.

During the year 501,801 births were registered in the Bombay Presidency, or a ratio of 30·50 per 1,000 of population. This is the highest ratio recorded since 1873. The district ratios show that this average was fairly maintained over the greater portion of the Presidency. In the Sind division it was still backward. In four of the five districts in this division the birth-rate varied from 15·92 to 18·81. For every 100 female births there were 109·2 male births. The total death-rate of the Presidency was 25·53 per 1,000. It varied in districts from 9·19 in Upper Sind Frontier to 41·97 in Khandeish. There were 111·06 deaths among males for every 100 deaths among females. Deaths were most numerous in June, July, and August. Compared with 1882, there was considerable increase under all the chief causes of mortality. Cholera prevailed with great severity, but the area over which it was severe was restricted. Although the deaths from cholera numbered nearly five times as many as in the year previous, the number of villages affected by it was only 3,200 out of a total of 24,431. Details regarding this and other diseases will be found in the next section.

In respect of birth registration the results in Coorg were even less satisfactory than in 1882. Special difficulties have, however, to be contended with in those remote hilly tracts. Although the year was one of good harvest and cheap food-grains, the birth-rate was estimated at only 13·43 per 1,000. The total death-rate recorded was 21·75 per 1,000 against 17·46 in the preceding year. Fevers are said to have been the chief cause of mortality, and deaths from them were most numerous during the months, January, May, and June. Cholera is said to have been totally absent.

As regards the death-rates in the Cantonments of the Bengal Presidency the smallest ratio (0·6 per 1,000) was recorded as usual in Fort William, and the highest in Cawnpore, where the death-rate was as high as 45·1 per 1,000. During 1882 also the mortality in Cawnpore was high,—namely, 40·8. Amritsar and Govindghar also recorded a high mortality, namely, 44·6 against 28·5 in 1882.

History of Chief Diseases.

Cholera.

The area over which cholera prevailed was somewhat greater than that of the preceding year, but the total number of deaths which it caused was less. From the annexed statement it will be seen that in several of the provinces the diminution was considerable, more especially in Bengal Proper, Assam, British Burma, and the North-Western Provinces, in which last the number fell from 89,372 to 18,160. On the other hand, there was a considerable increase in the Central Provinces, and a very large increase in Berar, Madras, and Bombay, in all of which the disease was severe.

Annual Deaths from Cholera in India, 1874 to 1883.

* Excluding Calcutta. † Statistics not available. ‡ Population not known.

As usual, considerable variations occurred in the seasonal prevalence of cholera in the different parts of India. Whilst the period of largest mortality occurred early in Bengal and Assam, it was late in the Central Provinces and Berar. In Madras the highest mortality occurred as usual during the cold season.

Compared with the preceding year, which was, however, one of marked prevalence, Lower Bengal suffered but little. The death-rate throughout the province was 1·36 against 2·75 per 1,000 of population in 1882. The ratio of 1883 is somewhat smaller than usual, the mean death-rate during the previous five years having been 1·61 per 1,000. The disease prevailed severely in three separate parts of the province—(*a*) a more or less triangular area having as a base the 24 Pergunnahs, the Sunderbunds, Backergunge, with a portion of Midnapore, and its apex in Maldah—the largest of the three severely affected parts; (*b*) a portion at the extreme north, including the districts of Darjeeling, Julpigoree, and a portion of Rungpore; and (*c*) a part of the north-western corner of the province, including portions or the whole of the districts Mozufferpore, Durbhunga, Sarun, Shahabad, Gya, and Lohardugga. In the intermediate parts which separate these three portions, the disease was much less prevalent. Although the disease existed in every district, it confined itself to few centres of population. Only 6·55 per cent. of the villages were attacked against 8 per cent. in the preceding year. The diminished mortality compared with that of 1882 was shared in equally by the rural and urban population. The urban mortality was 3·64 and the rural 1·27, whilst in 1882 these ratios were 4·79 and 2·67. Of the 47 districts enumerated in Table I. of the Appendix to this section, 12 only recorded a higher mortality than in 1882. In some of these the excess was great; but in many of these districts which show a lower mortality than in 1882, the diminution is marked. In Calcutta the total number of deaths was 2,037 against 2,240 in 1882. In 11 districts the death-rate exceeded 2 per 1,000, varying from 2·12 in Balasore and Darjeeling to 3·65 in the suburbs of Calcutta and 4·69 in Nuddea. The mortality in several towns was very high, *e.g.*, in Daudnagar, in the Gya district, the mortality was 23·20, in Julpigoree 12·07, and in Gya 8·85. In the province, as a whole, the disease was most prevalent as usual during the dry and hot months, April to June, and subsided with the commencement of the rains. But in Rungpore during the three months of greatest prevalence (May to July), the largest amount of rain fell.

In Assam the death-rate from cholera fell to 3·29 from 4·69 in 1882. The year 1882 was, however, one of exceptional prevalence of the disease. In 1881 the ratio was 1·12, and in 1880 it was only 0·74. In 1883, as usual, every district suffered, but the following four of the eight districts of this province show an increased prevalence of the disease as compared with the preceding year: Goalpara, Darrang, Sibsagor, and Lakhimpore. The highest mortality occurred in Darrang district, the mortality having been 9·23 per 1,000 against 3·37 in 1882. No details are given of the epidemic in this district by the Civil Surgeon. The season of greatest prevalence was April to July. In January many deaths were recorded, a continuance apparently of the epidemic which occurred at the end of 1882. The urban and rural mortalities were almost identical, namely, 3·25 and 3·29 respectively. It is worthy of note that Barpeta, a town on the right bank of the river in the Kamrup district, in which the mortality equalled 23·60 in 1882, suffered to the extent of only 1·14 in 1883. In the Goal-

para district the Dhubri sub-division suffered most, and there were 40 deaths among the coolies in the Dhubri depôt.

The history of cholera among immigrant coolies to Assam presents many features of interest. The subject has been noted in several late annual reports, more especially with reference to the introduction of a pure water-supply on the river steamers and at the depôts. The new water-supply was introduced in 1879, and soon after its introduction the mortality from cholera fell so greatly as to lead to a hope that the disease would ere long be banished from among the coolies. It will be useful, therefore, to compare the cholera mortality among them year by year, for the last few years. In the marginal table the number of deaths from this disease and the ratio of deaths per 1,000 are given since 1877. The contrast between the earlier and later years is very striking, and the result most satisfactory. When the reform in the water-supply was first attended with marked diminution in cholera mortality, it was pointed out that too hasty conclusions should not be drawn from the coincidence. Since then there has been an increase in the disease, and there have been one or two severe outbreaks on board the steamers, which show that the extinction of cholera which was hoped for has not been attained. In comparing the figures, moreover, a distinction should be made between the Goalundo and Dhubri immigrants. In the earlier years the bulk of the immigrants started from Goalundo; in 1883 the great bulk started from Dhubri. In other words, the voyage for the mass of the people concerned was reduced by five days, or about one-third of the whole time. And not only has it thus been reduced by five days, but those five days involve escape from five days spent on a river within the endemic area of cholera. These two factors are very important, and should not be left out of account. Still, notwithstanding the correction to be made for them, the results, as already stated, are very satisfactory, and they are all the more gratifying because they show that under improved sanitary arrangements other diseases have diminished in even a larger proportion than cholera. In the report for 1881 it was pointed out that the prevalence or absence of cholera in a country has a most important bearing on the extent to which bodies of men passing through that country may be expected to suffer from the disease, not only during the time of transit but also for some time afterwards. But while the concurrent history of cholera over the country is an important point to be considered in connexion with the history of the disease among the immigrants, no exact correspondence is to be expected between outbreaks among the two classes as regards time. It is always difficult to determine when a moving body of men like immigrants travelling on a river steamer come under the influence of the cause which produces cholera. Moreover, even within a given area, all places do not suffer at the same time. Many towns and villages escape altogether, while of those attacked some are attacked at an early period of the epidemic and others remain unaffected till it is near its close. All these questions are of much interest, but in a practical point of view it is of great importance that attention should be fixed on the actual measures of sanitary improvement which are capable of being carried out, and the experience of the river steamers shows how much good may be done by such practical work.

Year.	Number of Deaths on the River.	Ratio per 1,000.
1877	994	23·9
1878	794	33·8
1879	196	8·2
1880	23	2·2
1881	18	1·6
1882	196	6·5
1883	138	6·6

In the North-Western Provinces and Oudh the death-rate from cholera was 0·41, the smallest on record since 1877, when the statistics for Oudh were included, and less than it was in nine of the 12 preceding years. The mean death-rate for the previous five years is 1·11. The disease was most severe in Banda, where the mortality was 5·5, and next in Hamirpur, where it was 1·4. These districts lie to the south-west of Allahabad. In Banda the disease was severe also during the preceding year. Of the 49 districts of these provinces nine remained entirely free of the disease, and only seven of them suffered with any severity. These seven are Banda and Hamirpur, already mentioned, and Mirzapore, Benares, Ghazipore, and Ballia. The urban mortality from cholera was more than twice as great as the rural mortality, namely, 0·81 against 0·39. Out of 105,421 villages, 2,536, or 2·4 per cent., recorded deaths. The highest mortality recorded in towns occurred in Muttra 4·74, Banda 5·45, and Rasra 5·43. The disease began to rise in March, culminated in July, and then gradually sank to a minimum in December.

In the Punjab cholera showed itself by only 190 deaths recorded under this head. Most of them occurred in the Delhi and Gurgaon districts, the southern corner of the province. In the Delhi district there were, in all, 72 cases, with 39 deaths. The disease was said to have been imported into the Delhi district from Gurgaon; but as the Delhi district commenced to suffer about the 17th April, and the first case in the Gurgaon district did not occur till the 11th May, by which time at least 24 of the total 39 deaths had already taken

place in the Delhi district, the explanation falls to the ground. In the Gurgaon district there were 368 cases, with 121 deaths. The type of the disease was therefore mild. The disease appeared first in the Delhi district in April, and died out during June. In the Gurgaon district it appeared first in May, reached its height in June, and died out during September. A few isolated cases occurred in several other districts.

During 1883 the mortality from cholera in the Central Provinces was 1·84 per 1,000, or about the same as the average mortality of the years since 1869. It was somewhat greater than it had been in the two previous years, but considerably less than in some years since 1869. In that year the mortality was 10·50 whilst in 1878, when the next highest ratio was recorded, it was 5·53. In these, as in other provinces, the incidence of the disease year by year is characterised by great variations. In 1883 it prevailed most severely in the Satpura and Waingunga divisions. The former division comprises six districts, and of these Burhanpur and Chhindwara suffered most, whilst Seoni, and especially Mandla, comparatively speaking, escaped. In the Burhanpur district the mortality, 9·72, was higher than in any other district of the province. In the Chhindwara district it was 7·63. In the Waingunga division there are four districts, all of which suffered more or less severely, especially the Nagpur and Wardha districts; in the former, the death-rate was 6·96, and in the latter 7·62. In the Sambalpur district, no death was recorded as due to cholera. The epidemic began in May and reached its height in August; it thereafter declined; in December no death was reported. The deaths were reported from about 5 per cent. of the total number of villages. The urban mortality was 3·95, whilst the rural mortality was only 1·64. Some towns suffered very considerably, notably Narkher, in the Nagpur district (42·49), Pandurna (32·27), and Mohgaon (33·40) in the Chhindwara district.

In the **Hyderabad Assigned Districts** cholera prevailed extensively. The total death-rate from this cause was 10·6 per 1,000, against a mean rate of 3·2 during the previous five years. This is the highest mortality on record since 1869, with the exception of 1878, when it was 15·6. The death-ratio of 1883 was, however, very nearly approached in 1875, when it was 10·2. To this mortality, males and females contributed almost equally, for whilst among males it was 10·5, it was 10·7 among females. The province includes six districts, and in every one the disease prevailed severely. It was most severe in the Ellichpur district, where the mortality was 19·0. This district is the most northerly of the districts of the province. It was next most prevalent in the Basim district, which lies to the south of the province, where the mortality was 13·3 per 1,000. The lowest death-rate was recorded in the Buldana district, the most western district, namely, 6·7. The epidemic commenced in the Basim and Amraoti districts in April, and was confined to them until June, when upon the appearance of the rains it became general throughout the province. The first case occurred on the 16th April, in a village to the extreme south of the province, and another case occurred almost at the other extremity of the province on the 24th. Between the 8th and 10th June the districts of Buldana, Ellichpur, and Akola were invaded, whilst Wun, the remaining district, was attacked on the 21st June. Out of a total number of 5,564 villages 1,838 were affected, or 33 per cent. against 9·2 per cent. in 1882. The rural and urban mortality were much the same—10·6 in rural circles and 11·4 in towns. The great prevalence of the disease is supposed by the Sanitary Commissioner to have some connexion with the unusually heavy rainfall. The rainfall amounted to 53·14 inches against 39·49 in 1882, and an average fall of 33·17 during the fifteen years 1869 to 1883. The rainfall of 1883 was the heaviest on record during these fifteen years, the next having been 48·77 in 1878, when cholera prevailed with even greater intensity; for in that year the mortality due to it amounted to 15·6 per 1,000. There can be little doubt that there is an intimate connexion between the amount of rainfall and the general health. Dry years are, as a rule, healthy, and years of heavy rainfall unhealthy; but it is difficult to connect the figures of rainfall and mortality from cholera month by month. For example, the figures show that with 13·2 inches of rain in July there were 10,567 deaths from cholera, while, with only 9·1 inches in August, there were no less than 14,531 deaths. And again, with a fall of 11·90 inches, there were only 1,160 deaths from the disease in September. The history of cholera in this province furnishes an instance of hasty conclusions regarding the importation of the disease. The Civil Surgeon of the Amraoti district records his firm conviction that the disease was introduced by a woman who had come from the Poona district in Bombay, where he believed cholera was present. She arrived in Amraoti on the 21st April. The Sanitary Commissioner of Bombay, however, states that cholera first occurred in the circle from which this woman came seven days after she had arrived in Amraoti. Of the 16 people living in the house when she was ill, not one suffered.

In **British Burma**, cholera was much less prevalent than in the previous year, the mortality having been 0·60 per 1,000 against 1·96 in 1882 and 1·42, the mean of the previous five years. Although every district returned one or more deaths, and the disease was widely

spread, the proportion of villages attacked was very small. Only 126 out of a total of 14,811 villages returned deaths, or 0·85 per cent. The Bassein, Akyab, and Thongwa districts suffered most. Of the twenty towns in the province, Akyab (4·6) and Lemyethna (4·11) alone suffered to any extent. Ten of the twenty towns were almost entirely free. The total urban mortality was 0·76, while the rural mortality amounted to 0·58 per 1,000. With regard to the seasonal prevalence of the disease during the year, the largest number of deaths occurred in January. During February and March, the disease declined; during April it increased for a short time, and at the close of the year was almost gone.

Cholera was extensively prevalent over the Madras Presidency. The aggregate number of deaths exceeded that of any year since 1878. The total mortality it caused equalled 1·2 per 1,000 against 0·8 in 1882, and 0·6, the average mortality during the previous five years. The disease was entirely absent in three districts, and in three others it prevailed but slightly. It was most severe in South Arcot, Trichinopoly, Tanjore, and Tinnevelly; in all these districts, the average mortality during the previous five years had been small. In the Ganjam and Godávari districts, on the other hand, where the average five year mortality was greatest, the disease was but little prevalent. That the disease was widely spread, is shown in the fact that of the 76 towns in which deaths are registered, all but 26 returned deaths, or in other words 65·7 per cent. In some towns the mortality recorded was great, notably in Gudiyatam (North Arcot), where it was 34·2 per 1,000, and Karur (Coimbatore), where it was 25·2. Town mortality considerably exceeded rural mortality, viz., 3·8 against 1·1. Deaths were very numerous during January (4,413), but declined up to and during May, when there were only 497. They rose considerably in June and July: subsided during the following two months, to rise again rapidly, and reach their maximum in December, when 15,164 were recorded.

In the Bombay Presidency cholera was more prevalent than usual, but the area over which it was severe was not great. Its severity was confined to the North Deccan division. Throughout the Presidency 37,954 deaths were ascribed to it, and of these no less than 30,298 were recorded in the North Deccan Division. The total death-rate from this disease throughout the Presidency was 2·31 per 1,000, against 0·48 in 1882, and 1·33, the average death-rate during the preceding 10 years. But in the North Deccan division the death-rate was nearly three times as great as the mortality for the whole Presidency, viz., 7·12—the mean death-rate during the 10 previous years in this division being 1·59. In the Sind division, comprising five districts, the disease was entirely absent, but deaths occurred in every other district except Kanara in the Konkan division. In the South Deccan division cholera was less prevalent than usual, for the death-rate was only 0·79 against 2·17, the mean ratio for the previous 10 years. In the North Deccan division, where, as already stated, the disease was very prevalent, the death-rate varied from 9·81 in the Ahmednagar district to 4·37 in the Sholapur district. Throughout the Presidency 13·09 per cent. of villages were attacked, but in the North Deccan division the percentage rose to 32·9. The disease, as usual, commenced to appear in March and reached its highest intensity in July. Thereafter it subsided quickly. Of the 17 districts in which it appeared, it is worthy of notice that in seven the first cases occurred between the 6th April and the 6th May. These districts extend from Ahmedabad in the north to Dharwar in the south, a direct distance of about 550 miles. Direct railway communication reaches only one-half this distance. Ahmednagar is a district nearly half-way between the above districts, and the dates of the first cases noted in these three districts were as follows: Ahmedabad, 7th April; Ahmednagar, 9th April; Dharwar, 2nd May. Two interesting features regarding the history of cholera in fairs are illustrated during 1883. In the Kaira district (Gujarat division) a fair is held annually in September, and as cholera began to make its appearance in July, and grew in intensity very considerably during August, fears were entertained of its outbreak at the fair, and unsuccessful endeavours were made to postpone it. The fair was held in due course, and the disease did not break out at it. The mortuary statistics of the division generally show that during September the disease was speedily declining, the number of deaths during that month having been less than one-half what it was in August, whilst in the Kaira district itself in which the fair was held the number of deaths registered fell from 230 in August to 42, or nearly one-fifth in September. An illustration of an opposite result is to be found in the history of the fair held in the Sholapur district (North Deccan division). This fair was held in July. In the division cholera commenced in March, increased rapidly during April, May, and June, and reached its greatest intensity during July, when the fair was held. The disease appeared among the people attending it with great severity. The rural mortality from cholera throughout the Presidency was 2·37, whilst it was 1·87 per 1,000 in towns.

In Mysore cholera caused but little mortality. In all 124 deaths occurred, equal to 0·03 per 1,000 of population against 0·07, the mean of the previous five years. The disease was chiefly confined to the Shimoga district in the Nagar division, where 93 deaths occurred,

87 of them during November and December. In Coorg no deaths were ascribed to this disease.

The information upon the various circumstances attending or preceding outbreaks of cholera among the free civil population is always more or less incomplete; but that furnished in the reports on outbreaks among troops and prisoners is full of important details on many points connected with the disease. From these reports a few extracts may now be made.

As regards the effects of antecedent illness, fatigue, exposure to weather, &c., the following examples occur. In three instances among British troops the first cases occurred in men suffering from other diseases. The first man attacked in Fort William had suffered from chronic rheumatism, and two days before the attack was suffering from dysentery. At Chunar, where five cases occurred in all, the first man attacked had been a patient in hospital for 39 days, suffering from inflammation of the inguinal glands. At Lucknow the first case had been admitted into hospital three days previously for febricula. As examples of antecedent fatigue the following may be cited. At Sitabuldi the first two men attacked on the 13th August had been out shooting on the 11th, when they were exposed to the sun and returned tired. They are said also to have drunk water from little wayside pools. It should, however, be noted that in the Nagpur district, in which this station lies, an outbreak of cholera commenced in May and reached its highest intensity during August. At Bellary only one case occurred, and that was in the person of a delicate man who, when seized, had been all day without food. Among native troops also in several instances the first cases appeared among men ill of various other diseases. For example, at Calcutta and Ellichpur the first men attacked were suffering from fever; at Alipore the disease occurred in a patient who was suffering from dysentery; at Lucknow in a man suffering from mumps; at Ulwar in a man under treatment for bubo, &c. Instances may also be cited among native troops of men who were attacked shortly after rejoining their regiments from leave, or from duty elsewhere. For example, the first case at Silchar occurred in a man six hours after his return from sick leave which he spent in the Punjab. In a regiment at Benares only one case occurred on the 23rd August 1883, in a man who had returned five days previously from Banda. In the Banda district cholera was extremely prevalent at that time, and also to a lesser extent in Benares itself. Similarly at Roorkee, the first man attacked came from the Naga Hills; and in three regiments at Hingoli the first cases occurred in men coming from other stations in the neighbourhood. In the three last-mentioned cases cholera was prevalent throughout that part of the country. At Mominabad, a man of the 3rd Hyderabad Contingent was attacked with cholera on the 8th June. He returned at noon from Hingoli, whither he had gone with three others, escorting a prisoner. Cholera existed in Hingoli, though not severely; but the disease was becoming active in the surrounding villages. Irregularities of diet attending the Ramzan festival are often mentioned as possible or predisposing causes of the disease. Among the Native troops one such case occurred. At Bolarum, a man of the 1st Hyderabad Contingent had fasted during the day (31st July) and eaten a heavy meal at night. Amongst the jail population also instances resembling the above might be quoted. An excellent illustration of the probable effect of mental depression as a powerfully predisposing factor may be here mentioned. A prisoner had been in the Ranchi Jail in the under-trial ward for three months and nine days, and was convicted on a charge of murder on 31st May. After conviction he was much depressed in mind and occasionally refused his food. On the 25th June he suffered from diarrhœa. On the following morning the stools became choleraic in character; vomitting set in, and in a few hours he was collapsed; suppression of urine existed for two days. On the evening of the 27th he was better, but he died on the 30th of exhaustion. No other case of cholera was known to exist in the vicinity of the jail, or in the surrounding villages; but from the Sanitary Commissioner's Annual Report it appears that cholera was commencing at that time both in the Lohardugga district in which this jail is situated, and in the neighbouring district of Hazaribagh. Diarrhœa was the prevailing disease in the jail at the time.

Of the 12 stations garrisoned by European troops in which cholera occurred, diarrhœa was said to have been absent in 5, prevalent in 3, and but little prevalent in 4. In a small body of men marching from Chakrata to Meerut among whom cholera broke out, it is said that several men suffered from diarrhœa during and after the outbreak. In a similar body of men marching from Bareilly to Naini Tal diarrhœa was but little prevalent. Amongst men marching from Secunderabad to Bangalore it was not prevalent. Amongst Native troops of 21 stations (including one camp) in which cholera appeared, diarrhœa was absent in 16 and slightly prevalent in 5. Among 31 affected jails diarrhœa was absent in 14, prevalent in 13, and slightly prevalent in 4.

In all, 18 separate bodies of European troops were attacked, and in respect of 11 of these information is given of the number of buildings occupied and the number of these

which furnished cases. They occupied 189 buildings, and in 40 of these buildings, or 21·1 per cent., the disease appeared. In the Native Army complete information is available for 21 communities. These inhabited 3,610 buildings, of which 203, or 2·3 per cent., furnished cases. Similar information for the jails of India is available in the case of 29. They comprise 544 buildings, of which 99, or 18·2 per cent., furnished cases. Regarding individual communities, great variations are found between the number of buildings occupied and the number affected. Amongst European troops the largest proportion of buildings furnishing cases occurred in Allahabad, where of 25 buildings 13 were affected, or 52·0 per cent.; the lowest proportion occurred in Secunderabad, where of 16 buildings only one furnished cases, or 6·2 per cent. Among Native troops variations in this respect ranged from 33·3 to 0·10 per cent., and among jails from 100 to 1·4 per cent.

Regarding atmospheric and telluric conditions attending outbreaks little information of any value is contributed by medical officers. In several instances the weather at the time or immediately preceding outbreaks is described as "hot and sultry," "close," "heavy," or "still." In some cases a delay in the appearance of timely rain, or a stillness of air and cloudiness portending rain but without an actual fall, or an excessive fall of rain is noted. Amongst jail reports the following may be quoted. At Muzaffarpur the conditions are thus described: "Before and during the outbreak the weather was very close and sultry. Any "wind there was blew from the east. The season has been remarkable for the excessive "rainfall, the river having overflown its banks and flooded the town and surrounding country, "to an extent seldom, if ever, seen. The rainfall up to date has been 45·08 inches "compared with 38·07 inches for the whole of the year before, and an average annual fall "of about 40 inches. The rainfall for July was 8·83 inches against 3·39 last year, and for "August 12·08 inches against 15·48 inches." At Gorakhpur the conditions as respects rainfall were very different: "In August, generally a wet month, only 4 inches and 81 cents "fell, and in September 1 inch and 48 cents. Between August 14th and September 11th "the rainfall was but 66 cents of an inch. Between September 10th and September 20th, "1 inch and 18 cents fell in slight passing showers, though the clouds were frequently heavy "and seemed to portend a heavy downpour, and after the 20th the rainfall in Gorakhpur "itself was *nil*."

No case is adduced which favours the idea that the disease was spread by contagion. The positive information regarding the experience of those who came in contact with the sick is as usual altogether opposed to this idea. The results are shown in the marginal statement, and fully confirm the statement which has been so frequently made in previous reports—that attendance on cholera cases involves no danger greater than that to which all persons residing within a cholera-affected locality and exposed to the causes which induce cholera are subject.

	Number of Cases of Cholera treated.	Number of Attendants.	Number of Attendants attacked.	Percentages of Attendants attacked.
European troops	32	256	4	1·57
Native troops	307	677	15	2·22
Jails	308	476	12	2·51
Total	697	1,409	31	2·20

As regards the important question of the relation of cholera to local sanitary defects, some few illustrations may be given. In the Gwalior fortress the medical officer states that much of the surface drainage finds its way into the tanks which supply the ablution-rooms with water. The drinking-water also from the wells was not of good quality, as it becomes contaminated with soakage from without. Among Native troops unclean tanks, overcrowded huts, and insufficient ventilation are frequently noted as sanitary defects. In Kamptee especially, overcrowding and bad water containing an excess of chlorine were complained of. Around the Julpigoree Jail dirty pools were considered to exert unhealthy influence. The medical officer at this jail also notes that "during levelling of ground inside the jail "peculiar stinking emanations used to appear from the dug-up loose earth. It was a strange "coincidence that whenever the levelling operation was being carried on, fresh occurrence "of cholera used to take place." In the Buxar Jail night-soil was buried within the jail precincts. Most of the cases of cholera occurred in the blocks close to which the night-soil was buried. In the Gorakhpur Jail the water is regarded as suspicious. Bowel complaints have for long been very prevalent. The site of the jail is very bad.

The effect of movement was on the whole very favourable. For example, at Allahabad, where an outbreak occurred among the European troops, the affected bodies were divided into 12 parties, and these were all sent into camp; in 10 parties a single move was found sufficient to arrest the disease completely; whilst in each of the remaining two parties only one additional move was found necessary. Amongst Native troops an excellent illustration of the benefit resulting from movement is to be found in the cholera-affected troops at Kamptee. In the cases of the 4th L. C. and 20th N. I., among whom there was a severe outbreak, the regiments were divided into six parties, and in only one of them

was a second move found necessary. In these two regiments, 102 cases occurred in all, only five of which occurred after movement into camp. In Ellichpur, 44 cases occurred in the 2nd H. Infantry and 2 F. Battery H. C., but unfortunately no movement into camp was made. Several instances might also be quoted among the jails, but it will suffice to mention the results obtained at Julpigoree and Gorakhpur, where the largest number of cases occurred. In Julpigoree, 24 cases occurred in all, only one of which occurred after movement. In the Gorakhpur Jail, 57 cases in all occurred, and although movement was attended with benefit, yet this was not so conspicuous as it was in the above cases. The prisoners were divided into five parties, and from the time of movement 31 cases occurred among them. One party made three movements, during which 16 cases occurred; but no further move was found to be necessary. Another party made two movements, during which one case occurred. The remaining parties found one move sufficient.

The occurrence of an isolated case of cholera at Aden is interesting. The circumstances are as follows: A sepoy of the Bombay 22nd N. I. was admitted into hospital on the morning of 31st January 1888, suffering from ordinary diarrhœa. He appears to have been suffering from diarrhœa for a day or two before admission. This regiment had arrived in Aden in December 1881, or little more than a year previously. He was a weak man, and of irregular habits. The diarrhœa continued in spite of appropriate treatment, and at about 10·30 p.m. on the following day, undoubted symptoms of cholera set in. The dejecta were of the usual rice-water appearance; he suffered from violent cramps in the legs; his body was cold and clammy; the radial pulse was imperceptible, and there was complete suppression of urine. He shortly became collapsed, and died at 5 a.m. The acute symptoms of cholera lasted therefore about six and a half hours; shortly before death the body temperature rose and continued to rise after death. No post-mortem examination was made. In connexion with this case, the medical officer of the regiment writes: "Taking all the circumstances in "connexion with this seizure, I must admit it was a very unusual case. Aden is a detached "station having very limited intercourse with India. There was no cholera or marked "diarrhœa prevalent in the town or surrounding country, and as far as I could ascertain, the "patient had not been in the company of any one who had recently arrived from a district "where cholera was prevailing. The water supply for the troops cannot be contaminated, "as it consists of condensed water, and there is no fault in its distribution. Sanitation is, "however, very defective. The natives lines are overcrowded and built on a very bad site. "There is no drainage or system of conservancy in the native town. Each house in the town "has its cess-pit, which is never emptied, owing to the porous nature of the soil. The "wells in the town are, with few exceptions, contaminated with sewage; but this cannot "affect the troops, as only ablution water is obtained from this source. The question then "arises, Could there be a mistake in the diagnosis of a case simulating cholera? Or was "this a case of cholera of spontaneous origin owing to defective sanitation? I am inclined to "take the latter view, for, if this seizure was not cholera, what disease is there with such a "train of choleraic symptoms? It could not have been a case of acute enteritis excited by "tainted animal food, as the patient took nothing but sago and rice-water while in hospital, "and the same food as his companions previous to admission. Again, it could not possibly "have been a case of poisoning by a vegetable or other irritant poison, as choleraic symptoms "would not have come on only 38½ hours after admission, but immediately, unless the poison "was administered in hospital, and there is no reason for this supposition." This is a case full of interest in many respects. From the fact of its extreme isolation, it would doubtless by many be termed a case of cholera nostras; but by whatever name the disease may be called, the train of symptoms attending it was characteristically typical of Asiatic cholera, and had the case occurred in Bombay instead of in Aden, there is little doubt that it would have been regarded as a case of true Asiatic cholera.

Small-pox.

On the whole, the year 1883 was one of great prevalence of small-pox. The total number of deaths throughout British India amounted to 232,363 against 85,131 in 1882. They were, therefore, more than 2½ times as numerous as they had been in the preceding year. This large mortality fell mainly on the North-Western Provinces and Oudh. In these provinces 138,641 deaths from this disease were recorded, or a ratio of 3·14 per 1,000 against 0·60 during the preceding year, and 1·32, the average death-rate during the previous five years. This death-rate has only once been exceeded during the past 14 years, namely, in 1878, when it was 3·9. Looking more closely into the distribution of the disease throughout these provinces, it is seen that the districts of Oudh and Rohilcund north of the Ganges suffered most. The highest mortality in any single district occurred in Bara Banki in Oudh, where it was as high as 17·53 per 1,000.

After the North-Western Provinces and Oudh, the next highest death-rate occurred in Coorg; but omitting this province and Mysore, in which registration is very imperfect, the

excess death-rate over that of the preceding year was most marked in Berar, where the mortality of 1883 (1·5) exceeded that of 1882 by 1·4 per 1,000. Next in order of excess over the ratios of the preceding year come Madras, Bombay, Assam, the Punjab, and the Central Provinces. It is worthy of notice that the rural mortality exceeded the urban mortality in Assam, North-Western Provinces, Central Provinces, Mysore, and Coorg. In the remaining provinces in which the town mortality exceeded the rural mortality the excess was most marked in Berar, the town ratio having been 5·3 against a rural ratio of 1·30. In the Punjab and Berar more than 96 per cent. of the total number of deaths occurred among children under 12 years of age. In the North-Western Provinces unfortunately the information in respect of age is not given. In Madras, 61·3 per cent. of the total deaths occurred in children under 12 years of age.

Fevers.

Fevers caused a smaller mortality than in the two previous years. The total number of deaths ascribed to them throughout India was 2,879,659, against 3,125,366 in 1882. Compared with the previous year, 6 of the 11 provinces suffered more than in 1882.

But if the ratios of 1883 be compared with the average ratios of the various provinces during the previous five years, only two, namely, Bengal and Berar, show an excess. In Bengal the mortality from fevers was 13·81 against a five-year average of 11·87, and in Berar it was 20·3 against an average of 17·5. Of the remaining provinces which show an improvement over the average mortality, the North-Western Provinces exhibited the greatest decrease. Here the death-rate was 18·82 against 26·22 during the previous five years. The Punjab also shows a satisfactory improvement, 16·25 against an average of 21·94. Taking India as a whole, December was the month during which the largest number of deaths occurred from fevers. In most provinces the highest mortality coincided with the cold season; but in Assam and Coorg the month of greatest mortality was June; in Berar, which in comparison with its population suffered more severely than any other province, it was August, and in the Central Provinces it was September.

Bowel complaints.

The total number of deaths from bowel complaints throughout India was somewhat less than in the previous year, 261,623, against 280,016 in 1882. The number in 1883 was, however, still in excess of the number in 1881, namely, 259,150. The highest ratios occurred in Berar, 7·2; Assam, 3·19; and Central Provinces, 3·02. The smallest were recorded in Madras, Coorg, Punjab, and Burma, 0·7 each. Compared with the mean ratios of the previous five years, the Central Provinces, Berar, and Bombay, only show higher ratios during 1883. The highest mortality occurred in 6 out of the 11 provinces of India during August. In Lower Bengal, Punjab, and Madras, however, the largest number of deaths occurred during the cold season.

Injuries.

The total number of deaths from injuries and accidents was 76,059 against 74,041 in 1882. The largest number of deaths occurred as usual from July to September. Compared with the aggregate number of deaths in each province during 1882, the North-Western Provinces, Punjab, Madras, and Coorg show a diminution; but the reduction in all cases was trifling. It was 160 less in the North-Western Provinces, 389 less in the Punjab, 102 less in Madras, and only 3 less in Coorg.

All other causes.

Excluding deaths from the causes above considered, there were 889,243 deaths "from all other causes" as compared with 831,361 in 1882. There was therefore again a considerable increase in the number of deaths included under this category, as there had been in 1882 when compared with 1881. The result may no doubt be attributed to improved registration generally, and to the more careful separation of all other diseases. The largest proportion of deaths ascribed to "all other causes" was recorded in Berar, Central Provinces, and Madras, and the smallest in Bengal and North-Western Provinces (omitting Coorg).

Vaccination.

The province of Lower Bengal shows the largest number of vaccinators and the largest number of persons vaccinated. The greatest energy, however, appears to have been shown by the vaccinators in the Punjab, for the average number vaccinated by each vaccinator in that province was during the year 2,274 against 1,930, the next highest number in Bombay, and 923, the smallest number in Coorg. As regards the success attending these efforts, the best results in primary cases were obtained in Bengal, where 98·89 per cent. of the operations were successful. This high standard was very nearly approached in the Punjab, Central Provinces, Berar, Madras, and Bombay, in all of which the percentage exceeded 90. The largest proportion of the population was protected in the Central Provinces. In that province

the ratio of successful vaccination per 1,000 of population was 36·37: it was next highest in Bombay, 31·01, and least in the North-Western Provinces and Oudh. But perhaps a better idea of the amount of protection which is being afforded may be obtained by comparing the number of children under one year successfully vaccinated with an estimated birth-rate of 40 per 1,000. Such a comparison shows that the largest number of infants were vaccinated in the Punjab, where the percentage of estimated births successfully vaccinated was 56·5. The percentages in Berar 53·1, Bombay 47·0, and Central Provinces 42·8, were the next highest. In Bengal it was very low, namely, 9·7, but it was even lower in British Burma, 6·0, and in Assam, 6·7. The average cost of each successful operation was greatest in British Burma, where it was seven annas and three pie, and least in Bengal, where it was only one anna and six and a half pie. Special difficulties attend vaccination in Burma, and give rise to increased expenditure.

During the year under review there was an accession of 97 paid and 127 licensed vaccinators to the Vaccination Establishment of Bengal Proper. With the increase in the establishment, the total number of operations also rose from 1,261,425 in 1882–83 to 1,361,332 in 1883–84, and the number of successful cases from 1,229,058 to 1,329,328. This increase, however, was not general throughout the Province. In the Metropolitan, Darjeeling, and Sonthal Pergunnahs Circles, the number of operations decreased greatly, as compared with the year previous. The deaths from small-pox in the Metropolitan and Darjeeling Circles were only at the rate of ·06 and ·01 per 1,000 respectively, though in the Sonthal Pergunnahs Circle the mortality from this disease was high, both in the past year and the first quarter of the current year. Of the total operations, 1,284,467 were performed by the special establishment, and 76,865 by the vaccinators attached to dispensaries. In the operations of the special establishment the percentage of success in primary cases was 98·89 and in re-vaccinations 47·69. In the dispensary operations the success was at the rate of 94·60 per cent. in primary cases, and of 56·67 in re-vaccinations. Estimating the births at 40 per 1,000, the number of infants born during the year was 1,842,739. Of these, including all operations performed either by the vaccination establishment or at the dispensaries, 178,560 were protected by vaccination, or at the rate of only 9·7 per cent. The compulsory Vaccine Act was in force in 77 places; in many of them little opposition on the part of the people was met with; and it is satisfactory to find that, on the whole, there was an increase of above 5,000 operations in these places. The result of the working of the Animal Vaccination Depôts in Calcutta are encouraging. Bovine lymph was largely experimented with, both here and in all the vaccination circles of the province, and was very favourably reported on by most of the Superintendents. Throughout the province, in all 3,458 persons were vaccinated with lymph direct from the calf, and in these the proportion of success in primary cases was 91·61 per cent.; 1,112 persons were operated on with calf lymph in tubes with a success of 80·91 per cent.; and 27,703 were vaccinated with bovine virus transmitted by arm to arm, with success at 99·88 per cent.

In the North-Western Provinces vaccination is carried on solely by the special establishment. During 1883–84 the staff was strengthened by the addition of 14 first-class and 7 second-class vaccinators. The total number of operations, nevertheless, fell from 672,463 in 1882–83 to 649,067 in the year under report. This diminution, however, was restricted to the second and third circles. In the second circle, which includes Oudh, the diminution was, perhaps, only nominal, as recent disclosures have revealed the practice of fictitious entries which swelled the numbers in several of the past years. In the third circle the decrease is attributed in some places to paucity of subjects, and in some to want of encouragement on the part of the local authorities. As in the preceding year, in the first circle, comprising the Agra and the Meerut divisions, there was not a single case of re-vaccination. The primary operations numbered 225,774, or 26,919 more than in the year previous. Of these, 216,044 were successful, or at the rate of 97·40 per cent., against 97·56 in 1882–83. In the second circle, embracing Oudh, and also Rohilcund and Kumaon, the number of successful primary operations was 128,060, or 36,377 less than in the preceding year; this yielded a ratio of success at 87·76 per cent. against 91·91 in 1882–83. In the third circle, consisting of the Allahabad, Benares, and Jhansi divisions, the successful primary operations were 221,307 (against 242,160 in 1882–83), which yielded a ratio of 89·21 per cent, against 94·19 in the year previous. In all the districts of Oudh the average number of persons vaccinated by each vaccinator was very small, varying from 165 in Gonda to 675 in Bara Banki. Of the total population, only 12·94 per 1,000, and of the total births of the year only about one-seventh, were protected.

According to recent arrangements, vaccination in the Punjab was carried on by five distinct bodies of operators, viz., the district staff the cantonment and the Native State

establishment, and the medical officials attached to dispensaries. The total number of vaccinations performed during 1883–84 by all these bodies amounted to 633,062 against 499,697 in 1882–83. Of these, 592,852 proved successful, or at the rate of 93·6 per cent. The protection thus afforded extended to a little above 3 out of every hundred people of the province. Of the total operations, 624,873 were primary cases with success in 588,761 instances, and 8,189 were re-vaccinations with success in only about half the number of cases. The percentage of success in both classes of operations respectively was 94·25 and 48·71. Out of 734,912 children born during the year, 426,253 were protected by vaccination, or at the rate of 58 per cent.

There was some diminution in the total number of persons vaccinated in the Central Provinces, as compared with the preceding year. In all, 421,542 operations were performed, less than the number of the preceding year by 12,149. Still, the total number of the year under review was higher than that of any other year, and the percentage of success was somewhat greater. Of primary vaccinations 97·19 per cent. were successful against 96·94 in the previous year, and of re-vaccinations 78·94 per cent. were recorded as successful against 77·62. Both these percentages are very high and probably over the truth, and more especially the large proportion of success in re-vaccinations. Of the total number of primary cases successfully vaccinated 42·8 per cent. were children under one year of age.

The vaccination establishment in Berar was reorganised on 1st November 1883. According to the new scheme the number of vaccinators has been tentatively reduced from 54 to 42, and it has been arranged that, instead of carrying on vaccination for only six months as heretofore, they should work for 10 months each year, and be employed for the remaining two months of the year, May and June, when the time is not favourable for vaccination, in furthering village sanitation under the direction of Civil Surgeons. Owing partly to this change and partly to the paucity of subjects, due to exceptionally high mortality among children between one and five years of age, the outturn of work during the year under review was not so satisfactory as in some of the preceding years. In 1883–84 the total number of operations, omitting those performed in Melghat, amounted to 86,322 against 110,291 in 1882–83. Out of these, 79,204 were performed by the special establishment and 7,118 by the medical subordinates attached to dispensaries. But, although there was thus a falling off in the number of operations, it is satisfactory to find that the percentage of infants protected was 70·25 to the total number of persons successfully vaccinated in 1883–84 against 61·3 in 1882–83. The percentage of success in the operations by the special establishment was 92·98 in primary cases and 34·8 in re-vaccinations; while in dispensary vaccinations the ratio of success was 89·54 per cent. in primary and 42·5 per cent. in re-vaccinations. The average number of persons vaccinated by each vaccinator was 1,887; it varied from 2,030 in Buldana to 1,790 in Akola. From March to October only animal lymph, some of which was raised locally and some received from Bombay, was used. From the end of October the work was carried on by arm-to-arm vaccination or by means of lymph preserved on points.

Notwithstanding the reduction of three officers in the vaccination staff of British Burma, the amount of work accomplished during the year was satisfactory, as compared with the preceding year. The average number of operations performed by each vaccinator was 1,163 against 835 in 1882–83. These improved results have been attributed partly to the greater facilities which now exist for obtaining lymph. The Rangoon Vaccination Depôt, established during the year, also proved useful in this respect. The number of persons vaccinated during the year rose from 55,095 in 1882–83 to 73,269, showing an increase of 18,174 over the former. Of these, 66,792 were primary and 6,477 re-vaccinations. In all, 61,901 persons were successfully vaccinated, equal to 16·70 per 1,000 of population, against 46,343 or 12·50 in the preceding year. The number of successful primary vaccinations was 57,297 against 44,704, and of re-vaccinations there were 4,604 against 1,639 in 1882–83, the percentages of success having been respectively 85·78 against 85·34, and 71·08 against 60·41 in the preceding year. There was a falling off in the work done by dispensary officials. During the previous year the number of persons vaccinated by dispensaries was 390, and in 1881–82 it was 408, but during the year under report the operations performed fell to 28, of which 17 proved successful, or an equivalent of 60·71 against 69·55 per cent. in the previous year.

The statistics of vaccination fully testify to the great zeal and energy with which the authorities have for the last few years been working in Assam. The total number of operations in the province in 1881–82 amounted to only 45,246; in the following year they rose to 57,839. In 1883–84 the number stood at 88,693, and all of them, with the exception of

570, were primary cases. In addition to these, 671 operations were performed at the Dhubri Depôt, and it is presumed that many operations in tea-gardens have escaped registration, as they were never reported. In all the districts of the province, except Darrang, a larger number of vaccinations was performed than in the year previous. The total number of primary operations in the districts was 77,787. Of these 71,068 were successful, or at the rate of 91·36 per cent. 10,336 primary vaccinations were performed in the tea-gardens. Out of these only 5,300, or slightly over one-half, proved successful. In the province as a whole the ratio of success in primary cases was at 86·66 per cent., and in re-vaccinations at 73·88. The average number of operations performed by each vaccinator was 461. The compulsory Vaccination Act was in force in the municipalities of Sylhet and Gauhati and in the Municipality and Cantonment of Dibrugarh.

In Madras the vaccination establishment in 1883 was increased by six vaccinators. The increase in the number of operations also was considerable, the total being 749,146 in 1883 against 661,256 in 1882. Of the primary operations 720,349 were performed by the special establishment with success in 669,738 cases, or at the rate of 92·9 per cent., and 12,687 were performed by the medical subordinates attached to dispensaries with success in 10,274 instances, or at the rate of 80·9 per cent. In re-vaccinations the proportion of success was 45·1 in the operations of the special establishment and 42·3 in the dispensary operations. About 46 per cent. of the operations were verified during the year by the Deputy Inspectors of Vaccination. The proportion of persons protected by vaccination during 1883 rose to 21·9 per 1,000 of population from 18·9 in 1882. In the places where vaccination was carried out 738,388 births were recorded during the year. Deducting from these the deaths among children less than a year old, the number of children available for vaccination would appear to be 625,060. Out of these only 104,017, or a little more than one-sixth, were protected by vaccination during the year; although this number exceeded the preceding year's figure by 7,973, yet the large number of unprotected children would show that much still remains to be done. Animal vaccination was carried on during part of the year in the Madras, Guntur, and Tanjore Circles, and its introduction in other circles where good human lymph is not procurable was under consideration.

During the year under review there was an addition of six vaccinators to the staff in the Bombay Presidency. The total operations amounted to 878,312 against 851,444 in 1882–83. Out of these, 845,658 were performed by the special establishment, and 32,654 by the medical subordinates attached to the dispensaries. Of the operations by the special establishment 795,056 were primary vaccinations with success in 760,290 cases, or at the rate of 95·90 per cent., and 50,602 were re-vaccinations with success in 34,099 cases, or at 67·51 per cent. Out of the dispensary operations 30,127 were primary, and 2,527 were re-vaccinations, the percentages of success in these being at 91·51 and 54·69 respectively. The number of persons successfully vaccinated per 1,000 of population was 31·01 against 30·18 in the preceding year. The compulsory Vaccination Act has been in force in the city of Bombay for the last six years, and in the town of Karachi for four year. In the city of Bombay animal lymph only was used. In Poona, Broach, Nadiad, Ankleswar, Borsad, Rajkot, and Dhrangadra both animal and human lymph were in use. In all other places vaccination was carried on from arm to arm with human lymph. The total number of heifers inoculated was 935 against 645 in the preceding year.

There was no change in the vaccination establishment of Coorg. The increase of three vaccinators sanctioned last year did not take effect until 1st April 1884. The number of persons operated on by the special establishment amounted to 4,615, or 119 less than in the preceding year. Among these the percentages of success was at the rate of 88·70 in primary cases, and at 69·70 in re-vaccinations. The operations of the medical subordinates attached to dispensaries were restricted, as in previous years, to primary cases only, but in the year under review the total number was considerably more than in 1882–83. Estimating the births of the year at 40 per 1,000, the number of infants born in the province during the year would amount to 7,132. Of these, however, only 170 were protected by vaccination.

During the year 1884 only 985 persons were vaccinated in the British Army of India; in the case of 760 the results were successful, or an equivalent of 77·1 per cent. Both the actual number vaccinated and the proportion of success attending the operations were lower than in the preceding year.

Sanitary Works—Military.

The total amount expended on all military works during 1883–84 was Rs. 67,35,325-4-10. The details, as follows, have been furnished by the Examiner of Accounts, Military Works:—

Military Works.

	Rs.	a.	p.
Original works	26,90,982	14	7
Repairs	20,76,471	15	2
Establishment	13,60,112	5	2
Tools and plant	49,963	11	9
Barrack department	5,57,794	6	2
Total	67,35,325	4	10

The works of chief importance and magnitude that have been in hand were these—

Accommodation for Troops.—At Lucknow the substitution of permanent for temporary barracks for two battalions of British infantry has been in virgorous progress and is nearly finished. At Darjeeling new cantonments have been started to accommodate a mountain battery, a wing of British infantry, and a convalescent depot. At Peshawar the restoration of accommodation for the British garrison has been started and is in vigorous progress. This lies in the renewal or improvement of the old barracks so as to convert them into permanent barracks. (The outlay involved in this case is shown under the sub-head "Renewals and Improvements.") At Quetta a new cantonment to accommodate a battalion of British infantry has been in vigorous progress, and have been more than half carried out. Barracks, so arranged as to form a defensible position, has been built for the Native garrison at the North-East Frontier station of Buxa. At Peshin, the advanced position in Biluchistan, a defensible post has been nearly finished, with complete accommodation for half a battalion of Native infantry and a detachment of cavalry, the accommodation including provision for officers' quarters, hospitals, commissariat, transport, and all other accessories to make the position completely self-contained and independent. At Cherat, on the hills in rear of Peshawar, but accommodation is to be provided for a battalion of British infantry. The work has as yet not gone further than the preparation of designs. Designs and preliminaries have been under preparation for two posts at Sharigh and Dukki in Biluchistan similar to that at Peshin.

Accommodation for Officers.—Quarters have been in progress at Quetta and in the defensible post at Peshin.

Hospitals.—A large hospital for the Native garrison of Rawalpindi has been built. The conversion of existing buildings into station hospitals has been in progress at Rawalpindi, Morar, and Agra.

Prisons and other cognate disciplinary wants.—Military prisons have been finished at Dagshai, Sialkot, and Peshawar, and cells for prisoners have been finished at Kasauli and Murree, and have been in progress at Sialkot and Peshawar. Gymnasia have been erected at Delhi and the Murree gullies, and one has been in progress at Roorkee.

Renewals and Improvements.—The substitution of tiled for combustible roofing has been extensively carried out at Meerut, Delhi, Roorkee, Agra, Muttra, and Bareilly (as well as elsewhere); ceilings have been supplied to the barracks and in part to the officers' quarters at Nowshera; and improved flooring has been under supply to barracks and hospitals at Meerut Roorkee, and Umballa.

Commissariat Department.—Buildings for its general requirements have been in progress at depôts on the Bolan Road, at Rindli, and Bibinani. Bakery requirements have been completed at Roorkee, and are in progress at Landour, Bareilly, Shahjahanpur, and Rawalpindi. Steam flour-mills have been erected at Umballa and Rawalpindi. Slaughter-houses have been built at Saugor, Bhagsu, Mooltan, and Rawalpindi; and quarters for subordinates have been completed at Jubbulpore and Rawalpindi.

Military Roads.—There was only one great work in progress, but that is of special importance, viz., the Bolan high-level road from the terminus of the railway at the mouth of the pass along the Bolan valley and across the great *dasht* or plain to Quetta. Its length is 86 miles. The work consists of three parts—(*a*) the formation of the road; (*b*) its metalling; (*c*) its large bridges. (*a*) The formation, which includes the whole work except (*b*) and (*c*), was completed, except at two points; and at these and at all gaps for bridges temporary expedients had been devised for the passage of traffic; (*b*) metalling had been laid only at such parts where the road could not have borne the traffic even temporarily without it; and (*c*) no large bridges had been erected except two, where the road was impassable without them.

General Cantonment Works.—These embrace three classes of works,—(*a*) water-supply; (*b*) drainage and protective works; and (*c*) cantonment roads.

Under (*a*) *Water-supply*—

(i.) The supply to Peshawar has been completed and distributed, it is now under contemplation to extend it to the bazar;

(ii.) The extension of the Umballa water-supply was in progress;

(iii.) A *karez* for the supply of the post at Peshin had been constructed;

(iv.) The supply of Chakrata had been begun and the pipes ordered.

Under (*b*) *Drainage and Protective Works*—

(i.) The works sanctioned for Naini Tal had been carried out;

(ii.) The drainage of Quetta was in progress.

And under (*c*) *Cantonment Roads*—

The roads of Quetta were in progress.

Civil Sanitary Works.

Very little appears to have been done during the year to improve the sanitary condition of villages in Bengal. In the municipalities 34 per cent. of the total income was spent on sanitary works, or in actual numbers Rs. 17,54,096. Of this, however, Rs. 1,69,339 were expended for the treatment of the sick, and Rs. 16,533 on markets and slaughter-houses. Omitting these, the different items of expenditure were as follows:—

	Rs.
Conservancy	6,33,811
Drainage	96,097
Water-supply	1,60,449
Disposal of the dead	10,992
Construction, maintenance, and repair of roads	6,06,120
Other sanitary works	53,680
Total	Rs. 15,60,589

Of the amount for water-supply all but Rs. 36,769 was spent on the water-works in progress in Burdwan, on the extension of the Darjeeling water-supply to Kurseong, and on some repairs in the water-works at Dacca. Drainage schemes were inaugurated and in most cases taken in hand in Serampore, Ghattal, Berhampore, Lalbagh, Azimgunge, Dinagepore, Chittagong, and English Bazar in Maldah. In Nuddea, Dinagepore, and Moorshedabad, obstructions to drainage were removed, and some progress was also made in the Cuttack drainage scheme. Measures were being taken to extend the Calcutta water-supply to the suburbs of the town; and a project for supplying filtered water to the riverside municipalities from Howrah to Serampore has been under the consideration of the Local Government.

No sanitary works of any importance were accomplished in the villages of the North-Western Provinces and Oudh, but in many of the chief towns of these provinces much was done during the year under review to better their sanitary condition by improving the roads, drainage, sources of water-supply, conservancy arrangements, and in constructing wells, tanks, latrines, &c.

Of the sanitary works executed or undertaken in the Punjab during the year the following were the most important. Plans in connection with the water-supply and drainage of the city of Amritsar were in hand, those relating to the water-supply project being well advanced. The deep irregular ditch round the city of Amritsar was being filled up by the municipality, and when completed the land thus gained will be turned into gardens. Plans and levels for the drainage of Sialkot city have been prepared and submitted to Government for orders. At Simla the construction of the Sanjouli reservoir in connection with the water-works was being rapidly pushed on. A project was also under consideration for replacing by oval-shaped cast-iron drains the present objectionable V-shaped wooden drains which now carry off the drainage of the bazar into Combermere ravine, and a system of sewage pipes was also in hand to ensure a better and more effectual disposal of the sewage. At Georgegarh in Rohtak, where the water-supply was very deficient, a large masonry tank was nearly completed during the year. At Deoband in the Derajat division a covered drinking-water tank was constructed, masonry drains for water-supply were built at the Tank tahsil, and a scheme for improving the drainage of Banduwali outpost was in hand. In the Rawalpindi division drinking-water tanks were built on the Murree and Abottabad road. Compared with the three preceding years the municipalities showed on the whole greater activity in

attending to their sanitary wants. Out of a total income of Rs. 41,00,474, Rs. 12,41,831, or nearly one-third, were spent on sanitary works.

In the Central Provinces the only important civil sanitary works were the completion of the water-works at Jubbulpore and Hinganghat. In almost all the districts sanitary improvements of minor importance were carried out, such as the sinking of new wells, cleansing and repairing of tanks and wells, constructing road-side drains, filling up excavations, &c. Conservancy arrangements were also well attended to in all the municipalities in the province.

Of the sanitary works executed or undertaken in Berar during the year, the following were the most important: The *Kalapani* tank, which is intended to supply the town of Amraoti with water by means of pipes at an estimated cost of Rs. 3,02,646, was in progress. The *Wadali* tank, from which water is supplied both for cattle and drinking purposes at the station of Amraoti, was completed at a cost of Rs. 10,890. Works in connection with the *Hergowan* tank in the Amraoti district at an estimated cost of Rs. 19,775 were in progress. It is intended for cattle sent to the grazing tracts during the hot season. In Ellichpur the works in connection with the *Dhamangaon* tank, which is intended for cattle and is estimated to cost Rs. 14,144, were well advanced by the end of the year. In Melghat, weirs were being constructed at an estimated costs of upwards of 25,000 rupees. In Akola the *Janona* tank was under construction, and Rs. 25,853 were expended on it during the year. Altogether, Rs. 1,69,435 were allotted during the year to sanitary improvements. But out of it Rs. 1,56,878 only were expended. Compared with 1882, more money was spent on sanitary improvements in all the places, excepting the villages. The attention of all district officers, however, has again been called "to the necessity of carrying out the rules laid down in the "village sanitary code, and of preventing, as far as possible, the accumulation of filth inside "the boundaries instead of at suitable places on the outskirts of each village."

The work of sanitary improvement in Assam was restricted to towns and municipalities. The most important items were the completion of the water-works at Shillong and of the drainage-works of Goalpara, which have effected considerable improvement in the sanitary condition of that once water-logged town. Works in connection with the Gauhati water-supply also were in progress. They are estimated to cost Rs. 40,000. In the other municipalities, no special work was carried out; but in them much more was spent than in 1882 on street sweeping, cleaning of drains, and construction of roads and culverts. It was proposed that instructions should be issued to all district engineers to draw out plans for providing water to all the towns on the same system as has been devised for Gauhati.

In British Burma no special sanitary works of importance were undertaken during the year, except the scheme for supplying the town of Prome with river water. In almost all the principal towns many minor improvements and repairs, such as cleaning wells, constructing public latrines and drains, filling cess-pits, &c., were effected, and everywhere great attention was paid to conservancy arrangements. The total sum spent on these improvements during the year was Rs. 1,99,959. This is made up of Rs. 1,12,003 spent on markets; Rs. 67,920 on water-works; Rs. 10,412 on burial grounds; Rs. 6,637 on latrines; and Rs. 2,987 on drainage.

In the municipalities of Madras the amount allotted for sanitary purposes during the year under review was Rs. 12,02,870. Of this Rs. 6,31,611 were for the city of Madras alone, and the remainder, Rs. 5,71,199, for all the other municipal towns in the Presidency taken together. In these no work of any magnitude seems to have been executed. All that was done consisted mainly in the repairing and cleansing of tanks and wells, latrines, drains, dust-bins, markets, and slaughter-houses; in the construction of latrines, drains, and dust-bins; in the sinking of a few wells, and in some other minor works. In the fund circles Rs. 3,99,672 were sanctioned for sanitary purposes. Of this Rs. 1,63,006 were for conservancy, Rs. 40,030 for improvement of village sites, Rs. 84,581 for improvement of water-supply, Rs. 10,971 for sanitary arrangements of fairs, Rs. 58,068 for construction and repair of markets and slaughter-houses, and Rs. 43,016 for other sanitary objects. The works executed were mostly of the same nature as in the municipalities.

In the municipalities of the Bombay Presidency, out of a total income of 27 lakhs, nearly 11½ lakhs were expended on conservancy arrangements. In the Surat municipality measures were being devised for a thorough drainage of the city by means of underground drains; the public park was extended at a cost of Rs. 9,324; Rs. 2,109 were spent on new latrines and Rs. 18,566 on roads. At Ahmedabad Rs. 4,226 were spent in constructing new drains and repairing old ones, and an outlay of Rs. 1,75,744 was incurred on account of new roads and repairs to old ones. At Dakor Rs. 12,000 were spent on an embankment for a tank. At Broach some slopes were improved at a cost of Rs. 8,150. At Sholapur a branch sewer

of stone masonry, 330 feet long, and an open drain, 500 feet long, to carry off waste water into an underground sewer, were constructed during the year, and Rs. 5,819 were expended in erecting water stand-posts. At Ahmednagar Rs. 3,779 were expended on water-works, and Rs. 2,583 on drains and gutters. At Bhingar a tank was constructed at a cost of Rs. 1,000, and at Yeola six new latrines were built at Rs. 1,148. At Poona Rs. 7,362 were spent on roads, Rs. 2,089 on latrines and urinals, Rs. 7,965 on markets, Rs. 7,994 on water-works, Rs. 1,316 on the night-soil depôt, Rs. 3,476 on U-shaped drains, and Rs. 5,269 on cremation ghats. At Kurrachee Rs. 35,426 were expended on re-metalling roads. In the local fund circles nearly 2¾ lakhs of rupees were expended on sanitary improvements. Of these the following were comparatively important: In Ahmedabad Collectorate Rs. 11,004 were expended in constructing new wells and tanks and repairing old ones. In Kaira Rs. 16,765 were spent on 11 new wells and ten tanks. In Panch Mehals Rs. 3,895 in constructing new wells and tanks and repairing old ones. In Surat Rs. 23,776 on tanks, wells, and troughs. In Thana and Kolaba Rs. 13,344 and Rs. 5,504, respectively, on tanks and wells. In Ahmednagar and Nasik Rs. 14,117 and Rs. 7,883 were spent on new wells and improving old ones. In Belgaum Rs. 16,542 were expended on sanitary works, and in Dharwar Rs. 1,06,254 in repairing and improving tanks.

Of sanitary improvements in Coorg there is little to record. The Public Works Department spent only Rs. 140 in sinking a new well and repairing roads and old wells. In the Mercara municipality the conservancy establishment was maintained at a cost of Rs. 2,906. But for want of funds very little was done to improve the drainage of the town and to carry out the scheme for the water-supply which has been under consideration for some time. At Viranjendrapet Rs. 1,187 were expended on repairing roads, making drains, and other minor improvements, Rs. 2,196 on conservancy, and Rs. 1,050 in constructing a slaughter-house and a fish market.

General Remarks.

German cholera Commission.

Under the head of "General Remarks" the most important facts to be noted are the visits to India of two special Commissions, which came for the express purpose of inquiring into the cause of cholera. The first of these was the German Commission, which consisted of Messrs. Koch, Gaffky, and Fischer. After a few weeks in Egypt, where they had been engaged in similar investigations, they arrived in Calcutta on the 12th December 1883, and continued their work till the end of March 1884. They were provided with such laboratory and other accommodation as the Medical College could afford, and every endeavour was made by the College and other authorities to render them assistance. As the result of their labours they announced that the bacillus which they had first met with in Egypt, is an organism peculiar to cholera—that it is never absent in cases of cholera, and that it is never present in other diseases. They accordingly called it the "Cholera Bacillus," or from its peculiar curved shape the "Comma Bacillus." Their experiments led them to believe that this bacillus was destroyed in an acid medium, and this in their opinion explained why it proved inert when taken into the stomach of an healthy man or other animal. The bacillus was freely cultivated in gelatine and other media, but all endeavours to produce cholera by feeding animals with it or by inoculating them with it proved altogether unsuccessful. Notwithstanding these failures, the German Commission held that the comma bacillus was undoubtedly the cause of cholera. Shortly before they left Calcutta, they found this bacillus in a tank around which a few cases of cholera had recently occurred, and this was regarded as positive proof, not only that the bacillus is the cause of cholera, but also that it is distributed mainly through the medium of the drinking-water. No collected record has yet appeared of the labours of the German Commission. The account of their work both in India and Egypt is scattered over several official reports, and further information may be found in the address which Dr. Koch delivered before the Medical Conference held at Berlin on the 26th July 1884. Extracts from these reports and from Dr. Koch's address and a more detailed discussion of them will be found in the separate paper entitled "Cholera: what can the State do to prevent it?"

English cholera Commission.

The statements made by the German Commission were readily accepted on Dr. Koch's authority, and it was believed by many that the cholera problem which had so long puzzled mankind had at last been solved. They were not only of great scientific interest, but also of great practical importance. It was felt that their accuracy must be tested, and that they must either be verified or set aside. A separate Commission was accordingly despatched from London to examine the question afresh. The Commission consisted of Dr. E. Klein and Dr. Heneage Gibbes. They arrived in Bombay in the beginning of September, and

after a few weeks in that city they came to Calcutta and carried on their investigations in the same laboratory which had been used by the German Commission. They left India again early in December 1884. A full account of their work is now being printed in London.

In the investigations of both Cholera Commissions the want of a properly fitted laboratory, suited for work of this kind, was much felt. Arrangements are now in progress for providing a suitable building with all the other requisites. Dr. D. D. Cunningham, who was engaged for so many years in the cholera inquiry along with Dr. T. R. Lewis, has been again associated with the Sanitary Department of the Government of India, and will remain in charge of this laboratory.

ABSTRACT OF REPORT OF THE SANITARY COMMISSIONER FOR MADRAS FOR 1883.

(*Dr. M. C. Furnell.*)

European Troops.

Sickness and mortality among European troops.

The strength of Her Majesty's European troops during 1883 was 13,458. The total admissions into hospital amounted only to 991·0, which is the smallest number of any year on record since 1860. The deaths amounted to 10·0 per 1,000 only, which also is the lowest figure on record except 1880.

In the annexed table will be found the ratio per 1,000 of admissions, daily sick, mortality, and invaliding since the year 1870.

Years.	Ratio per 1,000 of Strength.			Invalided.	
	Admitted.	Daily Sick.	Died in and out of Hospital.	Change of Climate.	For Discharge.
1870 - -	1,481·5	63·2	19·7	76·4	6·6
1871 - -	1,211·5	56·2	19·1	29·7	12·5
1872 - -	1,352·3	59·7	19·2	26·8	11·2
1873 - -	1,270·8	59·3	18·5	50·6	12·7
1874 - -	1,141·2	57·6	13·4	29·5	8·3
1875 - -	1,096·3	56·9	14·8	60·3	15·5
1876 - -	1,132·9	55·2	16·1	31·9	10·9
1877 - -	1,172·2	58·2	17·2	36·0	10·2
1878 - -	1,379·7	65·0	22·1	36·6	9·1
1879 - -	1,438·7	68·4	16·8	34·8	10·2
1880 - -	1,385·4	68·4	9·9	15·0	8·0
1881 - -	1,164·8	68·2	11·1	18·6	8·8
1882 - -	1,069·4	59·8	10·4	17·6	12·0
1883 - -	991·0	59·7	10·0	20·1	13·6

There were 19 cases of cholera, 10 of which proved fatal. Eight of the 19 cases occurred in Kamptee with 3 deaths only. Five cases occurred at Secunderabad, all of which proved fatal. Considering that cholera has been very prevalent and fatal amongst the general population during 1883, Her Majesty's troops may be considered to have escaped wonderfully well.

There was 9 admissions in all under small-pox, with 1 death, which occurred at Secunderabad.

There were 1,385 admissions under all heads of fever, with 31 deaths. The admissions are fewer in number than either last year or the year before, but the deaths are more numerous. In 1882 we had 1,928 admissions with 26 deaths; in 1881, 2,880 admissions and 7 deaths only. Under typhoid fever there were 94 admissions with 29 deaths, or 30·8 per cent. of deaths to admissions. This is a larger number of typhoid cases than during the preceding two years, but the deaths are proportionally not quite so numerous as last year. Bangalore as usual had the greatest number of cases, 41 with 11 deaths; Secunderabad came next with 28 cases and 7 deaths. Continued and remittent fevers were answerable for 291 out of 1,385 admissions under fever, but with only 2 deaths, all under remittent fever. The greatest number of remittent (74) was at Secunderabad; the largest number (54) of continued fever occurred at Rangoon. As usual by far the largest entry was under intermittent fever; but no mortality.

There were 969 admissions under dysentry and diarrhœa; 513 cases of dysentery and 456 of diarrhœa, with only 3 deaths in all from dysentery. Considering what a heavy source of mortality dysentery was in former, say 20, years ago, these figures are very remarkable. Last year it was noticed that with 967 admissions there were only 6 deaths, and this year the report is even more favourable.

Diseases of liver were answerable for 422 admissions and 17 deaths. Bangalore had no less than 83 cases, but 1 death only; Rangoon 78 cases with 4 deaths.

There were not quite so many cases of venereal disease this year as last, but still the entries under this head were high, viz., 2,581, being a ratio of 243·2 per 1,000 strength.

Native Troops.

Sickness and mortality among Native troops.

The strength of the Madras Native Army on the 1st January 1883 was 28,160; during the year this figure was increased by recruiting and other causes to 30,968; there was a decrease by invaliding, discharge, and other causes of 1,787, leaving a total on 1st January 1884 of 29,181.

This office received returns from 24,998 troops only. The remaining 4,183 were serving beyond the limit of the Madras Command. Of this number (24,998), 17,347 were admitted into hospital, the average daily sick being 694·71. There were 310 deaths—240 in hospital and 70 out. This gives us a death-ratio per 1,000 of 12·4 to strength, which compares favourably with 1882, when the death-rate was 15 per 1,000.

The annexed table shows in a condensed form the admissions and deaths amongst the Native troops since 1868. It will be seen that 1883 compares favourably not only with its immediate predecessors, 1882 and 1881, but with any year until we reach back to 1871.

	Ratio per 1,000 of Strength.														
	1868.	1869.	1870.	1871.	1872.	1873.	1874.	1875.	1876.	1877.	1878.	1879.	1880.	1881.	1882.	1883.
Admissions -	707·4	702·5	630·6	603·9	1,067·9	883·2	772·7	777·7	726·2	832·2	705·2	1,001·2	1,275·9	948·7	866·0	693·9
Daily sick -	29·0	29·3	26·4	26·9	34·7	31·3	30·9	30·7	28·2	28·8	29·7	40·4	55·8	44·6	36·2	27·7
Deaths in hospital -	8·6	10·1	9·4	8·8	9·9	6·4	7·7	9·0	9·8	11·3	11·7	11·8	12·3	13·2	12·6	9·6
Deaths out of hospital -	1·4	3·6	2·6	1·8	2·4	1·8	2·0	1·5	1·2	1·7	1·6	2·4	2·4	3·0	2·6	2·8
Invaliding -	16·4	24·5	25·6	25·3	28·4	30·8	33·2	32·3	37·1	36·5	52·6	38·0	31·8	42·0	29·0	26·9

The principal causes of admissions into hospital were—fevers of all sorts 6,469, skin diseases 2,521, violence and accidents 1,570, and diseases of the bowels (dysentery and diarrhœa) 1,076, diseases of the heart and lungs 706.

The largest number of deaths was this year as last, entered under cholera. There occurred 136 cases altogether with 47 deaths. Kamptee, Vellore and Trichinopoly were the stations which returned the greatest number of cases and deaths. Two of these stations—Vellore and Trichinopoly—have a notoriously foul water-supply.

There were 31 deaths amongst the 6,469 admissions under fever—1 under febricula, 2 from continued fever, 15 from intermittent, and 13 from remittent fever. Unlike his European fellow-soldier, the sepoy seems to enjoy an immunity from typhoid fever; but, on the other hand, he succumbs to intermittent fever, which is seldom or never fatal to the European.

There were 63 admissions under small-pox—38 in Secunderabad alone—with only 3 deaths. This is a larger number of small-pox cases than usual, but the deaths remain much the same. Considering how prevalent the disease was during the year amongst the civil population, these numbers show that the Native Army was well protected.

Jails.

Sickness and mortality in jails.

According to the medical returns the average strength of all jails during the year under review was 7,699, the total admissions were 6,662, and the daily average sick 247·64. There died during the year 227 prisoners, being a death-rate of 3·4 per cent. on admissions, which is a considerably less death-rate than the last 10 years.

Out of a total of 6,662 admissions into hospital, no less than 1,998, or nearly one-third, were from fevers; 253 continued fevers, but of what form is not specified; there were no typhoid cases. The greater number (1,726) were under the head of intermittent. The largest number was, as usual, in the Rajahmundry central jail, viz., 845. It is a large, clean new jail, with 753 inmates; but from a recent inspection I am inclined to think this large number of intermittent fever cases arises from insufficient clothing. Rajahmundry is north and close to a large river, the Godavari; the variations in temperature, especially during the night, must be considerable. It was noticed the clothing was indifferent, not better than in the southern jails. There is no mortality, however, under this head, showing, as often previously remarked, how very amenable to treatment intermittent fever is. The mortality under all heads of fevers, considering the admissions were nearly 2,000, was small, only 8 cases, or about 4 per 1,000.

Cholera was answerable for 34 only of the 6,662 admissions into hospital, of which Cuddalore was responsible for 21 cases with 9 deaths. Cholera was very prevalent in the town of Cuddalore and neighbourhood during 1883. The medical officer in charge remarks:—"Epidemic cholera, which invaded the district in December 1881, continued during the "whole of last year (1883). In the jail there were three separate outbreaks in January, in

"September, and December. In January 11 prisoners were attacked and 7 died, in September "6 were attacked, of whom 2 died, and in December 4 were attacked, but all recovered. On "each occasion the prisoners were moved out to the camp jail at Mount Capper. On the first "occasion all the prisoners were moved and the jail buildings at Old Town were completely "vacated. On the subsequent occasions only about three-fourths of the prisoners were moved "out, some fifty, including civil debtors and under-trial prisoners, being left at Old Town."

The greatest number of prisoners (31) died in the Trichinopoly central jail, but this prison does not show the highest ratio of deaths per 1,000. Taken in the latter order we have Cotacamund (native jail) (65·69), Tanjore (86·21), Bellary (74·30), Cuddalore (73·86), Trichinopoly (55·16), and Kurnool (50·63). It will be as well to examine the cause of sickness and deaths in these respective jails.

In the Cotacamund native jail the undue sickness is attributed to "diseases mostly due to "alternations of temperature affecting gangs of men sent up from the plains, and weakly "men from Wynaad, whose constitutions were shattered by malarious fever." On turning to the tables we find the principal admissions into hospital were—fevers 37, respiratory diseases 12, diarrhœa 36. But the greatest number of deaths (5) is under "respiratory diseases."

Tanjore is an old jail and has long been condemned. The Medical Superintendent thus reports:—"The health of the prisoners for the year under review was not good. Dysentery and diarrhœa as usual constitute nearly two-thirds of the total admissions into hospital, and they as usual have been the chief causes of mortality. The diseases causing death were 7 from diarrhœa, 1 from dysentery, 1 from congestion of the brain, and the last from synovites on admission and pyæmia at his death."

In Bellary it is attributable chiefly to the inclemency of the cold weather, which was abnormally severe; the Superintendent reports:—"Out of a total of 8 deaths from dysentery "during the year 1883, 6 occurred in the rainy and cold weather, both of which were "abnormally severe, of these 6 cases, 2 were admitted into jail in 'indifferent' health, the "remaining 2 cases occurred, 1 in February, the other in June, the latter, a man, admitted "into jail suffering from dysentery, and whose health was marked 'bad' in the register, he "died shortly after admission into jail. As to the two cases of diarrhœa, 1 occurred in "March, a man who had been over 4 years in jail, the *post mortem* appearances were those "seen in cases, proving fatal from the effects of famine, so it is presumable he had suffered "severely from diarrhœa prior to his incarceration. The second case occurred in November "(cold season), 6 of the above cases of dysentery and one of diarrhœa, I attribute altogether "to severity of the weather, the variations in temperature being most trying, there was no "epidemic or anything wrong with the jail.

"Of the remaining number of deaths, 2 occurred in prisoners admitted into jail in "'indifferent' and 1, that of a man admitted in 'bad' health. Two other deaths of old men "were also recorded, both over 70; in these cases death may be fairly attributed to old "age. Another death also recorded during the year, was that of a man admitted into hospital "for rheumatism, but who died suddenly from 'embolism' as was elicited on making the *post* "*mortem*.

"Three other deaths, viz., 1 hepatitis, 1 bronchitis, running on to congestion of the lungs, "and 1 from general debility also took place during the cold and rainy season."

In Cuddalore the principal cause was epidemic cholera which caused 9 casualties. Four deaths took place from bowel-complaints induced principally by the diet now in use.

The Kurnool Superintendent is of opinion "there has been no undue sickness or mortality." It is a small jail with average strength of 79 convicts only and 4 deaths.

In the Trichinopoly Jail we have 31 deaths on an average strength of 561, equal to a death-rate per 1,000 of 55·2. During 1882 the death-rate was 162·5 per 1,000. Altogether during 1882 and 1883 174 prisoners died in the Trichinopoly central jail. This undue mortality—described by Surgeon-General Cornish in his inspection notes of August 1882 as the "old form of jail diarrhœa, dropsy, and dysentery which 20 years ago caused as "large a mortality in Madras prisons, undoubtedly due to *bad* or *imperfect nutrition*"—gave rise to a good deal of anxiety and inquiry, and for some time remained unexplained, but it is a melancholy satisfaction to know that it no longer remains a mystery; the cause has been elucidated.

General Population.

It has in various previous reports been remarked that the registration in Municipalities, carried on as it is by a registrar under the immediate supervision of the municipal authorities, is fairly correct. By G.O. No. 391 of 22nd February 1883, the civil medical officers have now been constituted also sanitary officers of their respective districts and are expected to

scrutinize the returns of births and deaths. This order has so recently come into force that it has as yet exercised no perceptible influence on district registration. According to a resolution of the Board of Revenue, in which Government concurred (G.O. No. 692, dated 3rd April 1884, Public), matters will remain the same for some time yet to come, and it will take a few years' experience to determine whether the G.O. No. 391 of 22nd February 1883 alluded to, if carried out in the manner here determined, has really effected any change in the mode and results of district registration.

The present returns are compiled from the census of 1881, the figures of which were not available for our last annual report. The total of population given by this census (exclusive of Europeans and Eurasians) is 30,835,771. There were 791,774 births registered during 1883, of which 404,937 were males and 386,837 females. The number of males born was in the proportion of 104·6 to every 100 females. The birth-rate per 1,000 is 27·7, the highest rate which has yet been reached. In England for the same period the ratio per 1,000 of births was 33·3, in Ireland 23·5. Births were much more numerous during the last than the first portion of the year. Out of a total of 791,774 births, 449,327 took place during the last and 342,447 during the first six months, and curiously enough each month of the latter had a higher total than the corresponding month of the first half of the year. On looking over past returns it is found that this preponderance of births during the last over the first half of the year constantly obtains.

The deaths registered during 1883 amounted to 541,930 in returns received from a population of 28,503,100. Of this number 278,485 were males and 263,445 females, giving 105·7 deaths of the former to every 100 of the latter. The actual number of deaths in 1883 was greater by 71,230 than in 1882, and the death-ratio per 1,000 is 19·0 against 16·2 of the previous year. But these ratios per 1,000 of births and deaths can after all, in India, be only approximate calculations, for it will be seen by studying the column of population how liable the totals are to be upset by a fresh numbering of the people. For instance, in 1871 the death-rate per 1,000 is 18·0, but in 1872 16·6 or nearly 2 per 1,000 less, and this not because less people died in 1872 than 1871, for if we look at the column of deaths we find nearly 60,000 more passed away, but because a census having been taken, it was found Southern India contained nearly six millions more people than the previous numbering gave us. So in the year under review the death-ratio per 1,000 suddenly rises from 16·2 to 19·0 not only because 71,230 more people died, but because also the new census has given us more than a third of a million less population.

The subjoined table shows the population, number of deaths registered, and the ratios per 1,000 for the last 15 years. Attention was drawn in last year's report to the very low death-rate per 1,000 for 1882, viz., 16·2, and it was then remarked that it pointed to a lower death-rate than obtained in the United Kingdom for the same year, viz., 19·2. The death-rate for this year, with a corrected numbering of the population, gives us, curiously enough, very nearly the same ratio per 1,000 as obtains in England, 19·0 to 19·7. It may perhaps be taken as evidence that our registration is getting yearly more accurate.

Years.	Population for which returns were received	Deaths.	Death-ratio per 1,000	Years.	Population for which returns were received	Deaths.	Death-ratio per 1,000.
1869	24,633,127	451,981	18·3	1877	29,209,542	1,556,312	53·2
1870	24,425,526	451,020	18·6	1878	29,127,205	810,921	27·8
1871	24,555,046	444,371	18·0	1879	28,991,267	549,390	18·9
1872	30,147,779	501,482	16·6	1880	28,778,097	454,101	15·7
1873	30,287,842	506,894	16·4	1881	28,676,375	465,682	16·2
1874	30,360,221	516,848	17·0	1882	28,887,111	470,700	16·2
1875	30,278,903	641,260	21·1	1883	28,503,100	541,930	19·0
1876	29,157,056	680,384	23·3				

Out of a total death-roll of 541,930, no less than 125,663, or nearly one-fourth, were children under one year of age. This represents a death-ratio of 158·7 per 1,000 of births, cholera, as usual, claiming many victims among infants.

The death-rate in districts amounted to 18·6 per 1,000 of the population against 24·9 per 1,000 in the town.

Below is given the usual table showing the deaths from different causes during the year under review compared with previous years. From this it will be seen that 1883 is the most sickly year we have had since 1878, the year succeeding, and still suffering from the effects of the famine. The year in other respects, viz., rainfall and food prices, had been a favourable

one, but the death-roll is swelled from all causes—not only cholera and small-pox, but also fevers and bowel-complaints.

Years.	Total Deaths.	Cholera.	Small-pox.	Fevers.	Bowel Complaints.	Injuries.	Other Causes.
1866 - - -	600,106	200,961	28,106	110,102	—	9,047	256,890
1867 - - -	372,026	33,205	27,907	112,511	—	8,613	189,790
1868 - - -	390,959	8,086	34,330	105,692	—	9,242	233,659
1869 - - -	451,981	21,034	17,448	132,346	—	9,310	271,843
1870 - - -	451,020	55,867	11,252	151,027	—	12,325	220,549
1871 - - -	444,371	17,656	20,823	192,469	38,928	15,323	159,172
1872 - - -	501,482	13,247	39,074	214,148	39,387	15,150	180,476
1873 - - -	506,894	840	51,784	222,843	36,392	14,251	180,784
1874 - - -	516,848	313	48,343	226,220	37,993	13,065	190,914
1875 - - -	641,260	94,546	24,775	252,042	37,484	12,421	219,992
1876 - - -	620,384	148,193	23,469	230,092	38,176	11,175	229,279
1877 - - -	1,556,312	857,430	88,321	469,241	133,366	16,460	491,494
1878 - - -	810,921	47,167	56,360	374,443	48,083	15,007	269,861
1879 - - -	549,390	13,296	17,840	285,477	23,218	12,619	196,940

1883 - - -	541,930	36,284	37,975	203,786	22,098	11,509	230,278

Cholera.

The cholera which invaded Madras at the fall of the year 1881 continued in the southern provinces during 1882 and all 1883. The area infected was much the same, viz., the collectorates and districts lying south of the Madras (South-West) Railway and freely traversed by this and the South-East Line—Tanjore, South Arcot, Trichinopoly, Tinnevelly, North Arcot and Madura, as mentioned in the last annual report, to which must be added this year Salem and Coimbatore. The northern district almost entirely escaped as in 1882, but towards the end of the year it crossed the border line of railway and crept up to Nellore, from whence, by the last reports which have reached this office, it is gradually ascending to the Northern Circars, keeping to the line of the canal.

The total number of deaths registered from cholera during the year under review was 36,284, giving a death-rate of 1·2 per 1,000 of the population, the average of the previous five years being 0·6. The rate per 1,000 in the districts, exclusive of towns, was 1·1, in the municipalities and towns of 10,000 inhabitants and upwards 3·8.

Small-pox.

Small-pox was very fatal during 1883: no less than 37,975 deaths were reported under this head. It represents a death-rate of 1·3 per 1,000 of the population, and is a greater mortality than any year since 1878. The districts which suffered most were Malabar, Kistna, Cuddapah, South Arcot, North Arcot, Madras, Salem, and Coimbatore. The district of Madras is in reality the town or city of Madras within municipal limits. Being the seat of a collectorate, it falls within the definition of a district. Here small-pox was very prevalent and attended with great mortality despite the energetic efforts of the municipal authorities and Inspector of Vaccination to counteract it by the energetic extension of vaccination. Fresh vaccine depôts were opened in all parts of the town, and an increased number of vaccinators was employed to push this prophylactic. The poor people are, however, so firmly wedded to the belief that the disease is a visitation of the goddess Mariamma, and to be looked upon rather as a beneficent mark of her favour than any misfortune, that all merely persuasive efforts on the part of Europeans seem useless to combat the epidemic. Unlike in Europe, the educated native classes in this country treat the matter with supreme indifference; misfortune or sickness occurring in any other but their own immediate circle is a matter for the parties concerned and cannot possibly, in their estimation, interest anyone else. Hence there is no effort on the part of the people themselves to grapple with an epidemic of this sort as a public calamity. The only remedy is compulsory vaccination, and the new Municipal Act, which has become law as this report is being prepared, provides for the future in the district of Madras.

Infants and children under twelve years of age, as usual, formed the largest bulk of the returns. Out of a total of 37,975, the child mortality amounted to 28,309.

Fevers.

Fevers have this year, like small-pox and cholera, been more fatal than last year. There were 203,786 deaths registered under this head, giving a death-ratio of 7·1 per 1,000 of the population. As before remarked, fevers, although creating no sensation, carry off annually more victims than cholera and small-pox put together; the total mortality from both these

complaints in the year under review (and that a bad year) being only 74,259 as against 203,786 from fevers.

The deaths registered from fevers in the districts of the Madras Presidency during each month of the year of 1883, shew that it is during the cold and monsoon months that the greatest number of victims succumb to fever; that it is more a climatic than a mysterious malarial malady. When the poor people learn how to protect themselves by proper clothing and food from rapid changes of temperature, then the muster roll of deaths from fever will diminish.

Bowel complaints.

The deaths under bowel complaints were more numerous in 1883 than any year since 1879. As remarked in last year's report, when cholera is rife deaths from bowel complaints are more numerous than usual.

Vaccination.

During 1883 there were 753,589 persons vaccinated, being an increase of 88,921 over the previous year. Of the total vaccinated, 736,662 were primary and 16,927 re-vaccinations. Out of 736,662 primary operations 683,384, or 92·7 per cent., were successful, being the highest percentage shown during the last 10 years. This shows an improvement both in the quantity and quality of the work done. 16,927 persons were re-vaccinated, 7,860, or 46·4 per cent., being successful.

The total operations performed in Local Fund districts during the year under review amounted to 595,214 against 528,413 during 1882, showing an increase of 66,801 cases. There was an increase in all the districts except Vizagapatam, Godávari, North and South Arcot, Coimbatore, Trichinopoly, and Tinnevelly. As in 1882, children over one and under six years of age were the most largely protected, next those above six years, and lastly infants under one year of age. The largest number of infants successfully vaccinated (18,681) occurs this year in Madura District, the smallest number (335), excluding Nilgiris, as usual in Malabar. The total number of infants under one year of age vaccinated in 1883 was 104,017; total number of births 738,388. In many districts infantile vaccination is very backward, and this is due to the almost insurmountable objection mothers have to early vaccination. On the appearance of the vaccinator in a village it is a common custom for parents to send their children away to a neighbouring hamlet, and stoutly deny having any. On the whole, however, infantile vaccination during 1883 compares favourably with 1882, viz., 14·0 against 13·8 per cent.

In all the municipal towns vaccination was carried on with more or less success during 1883. In many municipalities vaccination, especially infantile vaccination, is backward, and the only apparent remedy would seem to be a Compulsory Vaccination Act as introduced in Madras lately. The total number of operations in municipalities during 1883 was 96,274 against 86,481 in 1882, showing an increase of 9,793 for the past year. An improvement in the percentage of successful cases is observed in primary vaccinations, viz., 92·1 against 90·9. The number of infants vaccinated under one year of age in municipalities falls short of the registered births. The figures are, however, higher than those of the previous year, viz., 25,498 in 1883 against 20,570 in 1882.

The work done by medical officers and subordinates attached to dispensaries for 1883 is slightly in excess of 1882. There were 267 dispensaries from which returns were received; during 1882 the number was 254, showing an increase of 13 for 1883. The returns received from 15 dispensaries were *nil*. The highest number of operations (352) was done in a dispensary at Madurantakam, and the lowest (1) in Bimlipatam and Triplicane dispensary.

In some districts, such as Ganjam, Vizagapatam, and Kistna, inoculation is much practised and greatly preferred by the people to vaccination. As this greatly impedes the progress of vaccination, the Inspector of Vaccination suggests that an Act be passed prohibiting inoculation in those districts where a vaccinator is procurable. Inoculation was originally introduced by the British Government, so that its suppression would scarcely be an interference with the caste prejudices of the people.

Sanitary Works.

Municipalities.

The sanitary works executed and those that were in progress at the close of the year in each municipality consisted in the main in the repairing and cleansing of tanks and wells, latrines, drains, dust-bins, markets, and slaughter-houses; in the removing of prickly-pear bushes and other rank vegetation; in the construction of latrines, drains and dust-bins; in the sinking of a few wells, and in some other minor works.

Greater attention appears to have been paid in certain towns than in others to drainage and water-supply, especially in Madura. The situation of some towns is such that the question of an efficient and regular system of drainage is rendered difficult of solution.

The system of conservancy adopted in the several towns during the year under review was much the same as in former years. A scavengering establishment, supervised by a staff of inspectors, overseers, &c., is employed in each town to keep it clean and attend to its conservancy. The street sweepings, other refuse matters, and contents of dust-bins and latrines are removed daily and carted away outside of the limits of the municipality, and are either buried in trenches, thrown into fields, sold as manure, or consumed in cinerators and converted into poudrette for agricultural purposes. In some few towns the street sweepings and other inoffensive matters are made use of in filling up hollow places. The latrine accommodation in certain towns was increased by the erection of new latrines. During the year several of the municipalities have undertaken private scavengering: this is a step in the right direction, and it is hoped that in course of time it will be followed by all the municipalities in the Presidency. It will not only ensure greater cleanliness in the backyards of native houses, but may prove a source of income to the municipal funds. Particulars in regard to water-supply, drainage, and conservancy will be found in the abstract of the sanitary reports which follow. On the whole, the reports show progress year after year in conservancy and other sanitary arrangements.

The total estimated income of all the municipalities, exclusive of Madras, for the year 1883–84, amounted to Rs. 17,20,210, representing an incidence of Rs. 1.4.9 per head of population. In 1882–83 the income amounted to Rs. 15,96,920 and the incidence Rs. 1.3.3 per head of population according to census of 1881. Thus it will be seen that the income of 1883–84 exceeded that of the preceding year by Rs. 1,23,290; and it is gratifying to note that with this increased income the sanitary allotment also was raised from Rs. 4,95,536 in 1882–83 to Rs. 5,71,199 in 1883–84, representing a percentage to income of 38·2 against 31·0 in 1882–83. Excepting two towns, Calicut and Nellore, which show a low percentage of 15·1 and 17·8 respectively, the allotments made by all the other towns for sanitary purposes appear to be fair; in 36 towns the percentages ranged between 20 and 40, in 7 they were above 40 and below 50, and in 2, Cotacamund and Kumbakónam, the percentage was as high as 60·3 and 50·1 respectively. Increased provision over that for 1882–83 appears to have been made for all except one of the different specified objects of sanitation, viz., conservancy, improvements of water-supply and town sites, construction and repair of markets and slaughter-houses, and other sanitary objects. The allotment for sanitary arrangements during fairs and festivals is slightly below that of the preceding year, though the expenditure under this head for 1882–83 exceeded the sanctioned grant.

Of the total sanitary allotment, Rs. 3,93,828 were spent in nine months ending with December 1883, leaving Rs. 1,77,371 to be spent in the following three months of the official year. Taking, however, the figures for 1882–83, which represent the expenditure for the whole year, we find that out of a sanctioned allotment of Rs. 4,95,536, only Rs. 4,47,153 were spent, leaving Rs. 48,383 unutilized; excepting the expenses incurred for sanitary arrangements during fairs and festivals and construction and repair of markets, &c., which exceeded the sanctioned grant somewhat, the allotment for the other sanitary purposes do not seem to have been fully made use of.

Local fund circles.

Sanitary reports were received from all the circles, 30 in number. No material change was made in water-supply, drainage and conservancy during the year under review; the system was the same as last reported. The principal sources of water-supply were as usual tanks, wells, rivers and irrigation channels. But greater attention is now being paid to the conservation of the several sources used for drinking purposes in the majority of the circles. Drainage consisted, as usual, in side-ditches cut chiefly to carry off storm-water; excepting in a few cusbah towns, there is no regular system of drainage anywhere. The drainage from houses flows into cesspools or runs into the backyards, where the water soaks into the soil. Conservancy, on the whole, appears to have retrograded rather than improved, for the allotment under this head was reduced from Rs. 1,81,791 in 1882–83 to Rs. 1,63,006 in 1883–84, and the number of towns and villages conserved fell from 640 to 576. This backward movement is observable in seven of the circles, notably so in Guntúr, Tanjore and Madanapalle, where the number of villages conserved was reduced from 51 to 16, from 38 to 14, and from 28 to 5 respectively; in three other circles the numbers fell from 18 to 12 in Trichinopoly, from 30 to 25 in Negapatam, and from 24 to 23 in Cuddapah. It is remarkable that the Guntúr circle has fallen back as regards conservancy, for this circle used formerly always to head the list as to the number of villages conserved in it. No reason has been assigned for this retrogression. The available income, *i.e.*, one-third of the land-cess,

was the same as in the preceding year, viz., Rs. 43,333. The backwardness in Tanjore, Madanapalle, Anantapur (formerly Penukonda), and Trichinopoly was noted in last year's report also, and it is to be regretted that these circles have not endeavoured to retrieve their lost places on the list during the year under notice, but have made a still further downward movement. Scavengering establishments of varying strength were employed in 576 towns and villages during the year. These establishments were generally under the control of the local revenue officers, but in the Madura and Salem districts they were supervised by sanitary associations or local committees. In the Cuddapah district the contract system was in force in some places, and in Vizagapatam, besides the permanent scavengering staff in certain towns and villages, itinerating establishments were employed in other villages with the object of gradually improving the sanitary condition of all the villages in the circle; they seem to have done good work.

The sanitary works carried out during the year and those that were in progress, consisted as usual in the construction and repair of markets, slaughter-houses, latrines and dust-bins, in the excavating of tanks, and sinking of wells, in the repairing of tanks, wells and drains, in removing prickly-pear and other rank vegetation, and some other minor works. On the whole the reports show progress. The aggregate available income, *i.e.*, one-third land-cess, amounted to Rs. 13,84,627 for 1883–84 against Rs. 13,41,991 for 1882–83, *i.e.*, the income for 1883–84 exceeded that of the preceding year by Rs. 42,636. Sanitation does not, however, appear to have benefited by this increased income; it seems to have suffered for the aggregate budgeted sanitary allotment, including the item construction and repair of markets and slaughter-houses, fell from Rs. 4,37,259 for 1882–83 to Rs. 3,99,672 for 1883–84, *i.e.*, it was less by Rs. 37,587 during the year under review. Two of the most important objects of sanitation, viz., conservancy and improvement of water-supply (the greatest need in India), appear to have suffered by the reduction. The allotment for conservancy, as might have been expected by a reduction in the number of towns and villages conserved, fell from Rs. 1,81,791 in 1882–83 to Rs. 1,63,006, that for the improvement of water-supply from Rs. 1,23,043 to Rs. 84,581; there appears, however, an increase in the allotments for the improvement of village sites and other sanitary objects of Rs. 9,089 and Rs. 15,972 respectively. The provision made for sanitary arrangements during fairs and festivals was the same as that for the preceding year, and the allotment for the construction and repair of markets and slaughter-houses fell from Rs. 62,570 to Rs. 58,068.

Taking the figures for the year 1882–83, which represent the expenditure for the complete year, we find that out of a sanctioned allotment of Rs. 4,37,259 only Rs. 3,49,521 were spent during the year, leaving Rs. 87,738, or 20·0 per cent., unexpended. The allotments under every one of the items except "other sanitary objects" (and what these consist in is not known) have not been fully utilized, which is very much to be regretted. It cannot be said that nothing was required to be done and so the money was not expended. It is to be hoped, however, that recent orders of Government and of the Board of Revenue on the subject will in future have the desired effect towards the complete utilization of funds placed at the disposal of the local authorities for sanitation, and that as skilled agency has now been provided by the appointment of district medical and sanitary officers for indicating and devising measures by which the funds of the local boards can be most advantageously expended, conservancy and improvement of village sites and water-supply—the greatest sanitary needs of a locality—will receive due attention, and the expenditure on their account will be strictly watched.

In the year under review (1883–84) the available income, as previously stated, amounted to Rs. 13,84,627; of this sum Rs. 3,99,672, or 28·8 per cent., were sanctioned for sanitary purposes, including the provision made for the construction and repair of markets and slaughter-houses. Excluding them, the allotment stands at Rs. 3,41,604, or 24·6 per cent. of income. Of the total amount, Rs. 2,11,865 were expended in nine months of the year ending December 1883, leaving the remainder, Rs. 1,29,739, to be spent in the following three months. 28·8 per cent. of income may be accepted as a fair sanitary allotment on the whole, though it falls somewhat short of the minimum. In some few circles the percentage has been very low, viz., Malabar 2·5, Canara 7·0, Madanapalle 10·3, Cocanada 13·8 Chatrapur 14·3, and Madura 15·0. For exceptional reasons the allotments made by the Local Boards of Malabar and Canara are always small, and in Madura the allotment is supplemented by contributions from sanitary associations. In all the other circles the percentages were above 20, and in some they were as high as 83 in Coimbatore, 55 in Negapatam, 52 in Nilgiris, 51 in Ellore, 43 in Hosur, 35 in Chittoor, 33 in Cuddalore, Masulipatam, Salem, and Kurnool, and 30 in Tanjore.

General Remarks.

During 1883 every municipal town in the Presidency was visited by the Sanitary or Deputy Sanitary Commissioner. The inspection reports were forwarded as usual to Government, and circulated to the President and Vice-President of the various Municipalities and Local Fund Boards.

It was noticed in last annual report that considerable progress had been made in sanitary matters; this progress has been in many places, as lately remarked by Government, fully maintained. The Commissioners are becoming more and more alive to their responsibilities and duties. The President of the Municipality of Madura speaks in the highest terms of the activity which is exhibited by the members in the management of local affairs, and the Right Honourable the Governor in Council believes that other municipalities are in no way behind Madura in public spirit.

During April, May and June, the present incumbent was absent on privilege leave. Surgeon-Major Bidie, C.I.E., acted as Sanitary Commissioner during those months. On my return to duty, one of the first questions which came under consideration was a supposed epidemic sickness amongst fish, rendering them unfit for food. As fish form an important portion of the diet of fully two-thirds of the people, it was at first sight a serious question. The alarm on this point had been started at Pondicherry, and had gradually spread up the coast to Madras. The subject was referred to this department, and, as the report is short, it is given *in extenso* (Appendix B). It is but fair, however, to mention that although the report is concise, this in no way represents the amount of labour it entailed. Every morning from 6 A.M. to 10 A.M., for several weeks, was given up to dissection and microscopical examination, and moreover, a mass of literature on the subject had to be mastered. It was gratifying to receive, after the report had gone in to Government, a note from Professor Cobbold, fully corroborating the conclusions arrived at. The subject was new and intensely interesting, but I am sorry that subsequent touring and the increased work in the office brought about by the late re-arrangement of sanitary work in the provinces have precluded my finishing the sketches alluded to.

During the year under review the German Cholera Commission, consisting of Drs. Koch, Fischer, and Kaffgy, visited Madras. Unfortunately their stay was very short; they were simply *en route* to Calcutta. They did me the honour to call, and I tendered them all the assistance and information in my power. At the time of their visit cholera was raging very severely at Madura, whither I invited them to accompany me, but their engagements, much to their regret, precluded their doing so.

ABSTRACT OF REPORT OF THE SANITARY COMMISSIONER FOR BOMBAY FOR 1883.

(*Deputy-Surgeon-General T. G. Hewlett.*)

Introductory.

Healthiness of the year.

The year 1883, as will be shown more fully in the following section, was an unhealthy one. There was not only a widespread epidemic of cholera, but small-pox prevailed to a large extent over a great portion of the Presidency, whilst fevers also were in excess of the mean.

Fears were at one season of the year entertained that the locusts would cause a scarcity, if not famine, over extensive areas of the Deccan and the Konkan, but the energetic measures taken in the affected districts by order of Government for their destruction, were in a great degree successful, whilst the strong easterly breeze that set in at the termination of the rains, blew them in great numbers out to sea, where they perished.

Rainfall.

Unusually heavy rain accompanied the setting in of the south-west monsoon in June, whilst the easterly rains in September and October were more abundant and prolonged than usual, so that with the exception of the collectorates of Kaládgi, Kaira, Ahmedabad, and Sind, the rainfall in each of the remaining districts of the Presidency was above the annual mean.

General Population.

Vital statistics.

The total population of the Presidency, including the military, amounted at the census of 1881 to 16,454,414 (males 8,497,718, females 7,956,696). The total area occupied by this population is 123,860 square miles, and the average density was 132·85 per square mile.

In the Presidency of Bombay, including Sind, during 1883, the births of 261,966 males and 239,835 females, or a total of 501,801 children, were recorded against 255,927 boys and 235,419 girls, or a total of 491,346 children, in 1882. The births for 1883 are thus 10,455 in excess of those for the previous year, whilst they exceed the mean of the preceding 10 years ending 1882 by 154,391.

The following table shows the number of births registered in each year from 1873 to 1883, their ratios per 1,000 of population, and the proportion of males to females. The ratios are calculated on the total population, not as hitherto on the total of male and female populations :—

Years.	Number of Births Registered.			Rates per 1,000 of Population.			In every 100 Born there were		For every 100 Male Births the Females were
	Males.	Females.	Persons.	Males.	Females.	Persons.	Males.	Females.	
1873	*152,520	*137,799	*290,319	9·39	8·49	17·88	52·54	47·46	90·35
1874	174,966	157,842	332,808	10·81	9·75	20·56	52·57	47·43	90·21
1875	178,392	161,927	340,329	11·05	10·01	21·06	52·49	47·51	90·52
1876	181,872	163,612	345,484	11·24	10·11	21·35	52·64	47·36	89·96
1877	164,262	147,399	311,661	10·15	9·11	19·26	52·75	47·25	89·73

* N.B.—Inclusive of still-born.

It is satisfactory to notice the progressive improvement that, except in the three years of famine, has taken place in the registration of births, yet the birth-rate for 1883 (30·50 per 1,000) is below the birth-rate of some European countries.

The number of births registered in 1883 is higher in each of the five divisions than that recorded in 1882 except in the Northern Deccan, in which only 139,000 births were

registered against 144,865 in the previous year; but the registration still continues to be very defective in the Konkan and in Sind, and the carelessness exhibited in these two districts in this respect destroys the value of our statistics.

The total increase for the Presidency was 9·15 per 1,000 of population above the mean of the preceding 10 years, whilst in the following 13 districts, viz. :—Poona, Sholápur, Belgaum, Dhárwár, Kánara, Kolába, Thána, Broach, Kaira, Ahmedabad, Hyderabad, Thar and Párkar, Upper Sind Frontier, the number of births in 1883 is higher than in 1882.

It is most disappointing again to notice, as Mr. Lumsdaine pointed out in his last report, that the registration of births, in the city of Bombay, shows no improvement although an increased registration establishment has, for upwards of three years, been entertained. The highest birth-rate in 1883 (44·09) took place in the Dhárwár Collectorate, and the lowest (15·92) in the Hyderabad Zillah.

The birth-rates for the Presidency among the urban and rural population were respectively 25·07 and 31·29 against 25·07, and 30·56 in 1882; the birth-rates recorded among the rural population of each district except in Kánara, Ratnágiri, Ahmedabad, Karáchi, Hyderabad, and Shikárpur were higher than the birth-rates registered in the town circles.

In Kándeish, Násik, and Bombay City the birth-rates in 1883 were lower than the death-rates. This may perhaps, as regards Kándeish and Násik, be partly due to there having been a severe epidemic of cholera and small-pox, but in Bombay City it is clearly due to defective registration. In Ahmednagar and Poona Collectorates the birth and death-rates were nearly balanced. In all the other districts the recorded birth-rates are higher than the recorded death-rates. This is especially noticed in the following districts :—

Districts.	Birth-rates, 1883.	Death-rates, 1883.	Districts.	Birth-rates, 1883.	Death-rates, 1883.
Sátára - - -	38·35	23·15	Kaládgi - - - -	35·14	21·46
Belgaum - - -	40·60	22·23	Kaira - - - -	36·03	25·11
Dhárwár - - -	41·09	24·74			

It is most satisfactory to notice this fact especially in the districts of Belgaum, Dhárwár, and Kaládgi which suffered so severely during the famine, and the high birth-rate prevailing in them not only proves that the fecundity of the people has returned to its normal state, but is in accordance with the law that "after the ravages of plagues the births increase; for "example, the London bills of mortality showed 64,544 christenings in the ten years, "1651–60, before the Great Plague, and in the ten years 1661–70, including the year of the "Great Plague, 106,755 births."—*Farr.*

In 1883 among the Civil population in the town, rural and Cantonment circles of the Presidency of Bombay the deaths of 221,110 males and of 199,088 females, or a total of 420,198 persons, were recorded. In the previous year 343,418 deaths, or 76,780 less than in 1883 were registered. The following statement shows the number of deaths registered in each year since 1872 :—

1872 -	367,057	1876 -	368,260	1880 -	328,673
1873 -	290,972	1877 -	627,708	1881 -	381,450
1874 -	278,652	1878 -	532,951	1882 -	343,418
1875 -	375,718	1879 -	387,542	1883 -	420,198.

Excluding the famine years (1877–78) the deaths in 1883 were far more numerous than in any year of the series.

The computed death-rate per 1,000 of population in 1883 was 25·53 against 20·87 in 1882, the decennial mean being 24·06. Omitting Sind, where the mortuary registration is extremely defective, the death-rate in the other parts of the Presidency amounted to 27·32 per 1,000, of population.

The deaths in 1883 by districts ranged from 41·97 per 1,000 in Kándeish to 9·19 in the Upper Sind Frontier. In 1882 the maximum ratio (26·16) was in Bombay City and the minimum (9·90 in the Upper Sind Frontier.

In 17 districts the death-rate per 1,000 of population in 1883 was higher than in 1882, the difference being most marked in—

Kándeish where	41·97	deaths per 1,000 were registered against	22·07	in	1882.
Násik . „	33·80	do.	do.	24·77	do.
Ahmednagar „	38·56	do.	do.	19·51	do.
Poona „	28·60	do.	do.	17·84	do.
Sholápur „	29·11	do.	do.	18·99	do.
Surat „	31·44	do.	do.	22·81	do.

It was also higher than the annual mean of the preceding 10 years in the following 12 out of the 24 districts, viz. :—

Kándeish.	Poona.	Thána.	Thar and Párkar.
Násik.	Sholápur.	Surat.	Shikrápur.
Ahmednagar.	Kolába.	Hyderabád.	Upper Sind Frontier.

The mortality amongst infants under one year and children above one year but under 5 is terribly high in comparison with other periods of life. In fact the deaths in children under 5 years of age formed 40·54 per cent. of the total deaths. The period of greatest immunity was in the period "above 10 and under 15," the rate being 7·75 per 1,000. For those "above 60 and upwards" the mortality was at the rate 58·73 per 1,000. The percentage on total deaths amongst infants under one year is 21·35 against 22·11 in 1882. For those "above 1 and under 5" the percentage on total deaths is 19·19 against 16·72 in 1882. For old people "above 60 and upwards" the percentage on total deaths is 10·38 against 11·28 in 1882.

The subjoined table shows the deaths in 1883 arranged according to the specified causes laid down by the Government of India and contrasted with the results for 1882 and the mean of the preceding 10 years :—

Deaths by Causes.	Mean for 10 Years, 1873–82.		1882.		1883.	
	Number.	Ratio per 1,000 of Population.	Number.	Ratio per 1,000 of Population.	Number.	Ratio per 1,000 of Population.
Cholera	21,621	1·33	7,904	0·48	37,954	2·31
Small-pox	6,522	0·40	1,630	0·10	13,404	0·81
Fevers	255,531	15·70	243,454	14·80	266,741	16·21
Bowel complaints	33,150	2·04	28,353	1·72	35,292	2·14
Injuries	6,440	0·40	5,913	0·36	5,978	0·36
All other causes	68,270	4·19	56,164	3·41	60,829	3·70
All causes	391,534	24·06	343,418	20·87	420,198	25·53

Cholera.

During 1883 cholera caused 37,954 deaths throughout the Presidency. The epidemic was most severely felt in the Northern Deccan Registration District, as 30,298 of these deaths were recorded in it, of which 10,914 took place in Kándeish; but the highest death-rate (9·81 per 1,000) occurred in the Ahmednagar Collectorate. No deaths from this disease were recorded in the Sind District.

The deaths from cholera in each of the 18 years ending 1883 were as follows :—

1866	23,027	1872	15,642	1878	46,743
1867	5,143	1873	283	1879	6,937
1868	6,347	1874	37	1880	684
1869	52,330	1875	47,555	1881	16,694
1870	2,666	1876	32,117	1882	7,904
1871	5,821	1877	57,252	1883	37,954

so that the number of cholera deaths in 1883 exceeds the decennial mean by 16,333 and those in 1882 by 30,050, and was only exceeded in 1869, when 52,330 deaths were registered, in 1875 when 47,555 were recorded, and in 1877 and 1878, when the deaths ascribed to cholera amounted to 57,252 and 46,743 respectively.

Taking the mortality by districts, the highest number of deaths 10,914 = 8·82 per 1,000 of population took place in Kándeish District, whilst the highest death-rate occurred in the Ahmednagar District, as there were 7,368 deaths = 9·81 per 1,000. Next in order comes the Poona District, where the deaths amounted to 5,279, and following it the Násik District, where they were 4,193. In the Sholápur and Thána districts they were between 2,000 and 3,000. In the Kaládgi, Sátára districts, and in the city of Bombay between 1,000 and 2,000 deaths were recorded. In the remaining 10 districts they were under 1,000. It is worthy of special note that not a single case of cholera was reported in any of the five districts of the Sind division.

Out of the 285 registration circles into which the Presidency is divided (223 rural, 55 town and 7 cantonment circles), 174, namely,—131 rural, 37 town, and 6 cantonment circles were affected with cholera.

These deaths are distributed over 3,242 registration units, viz., 37 towns, 6 cantonments, and 3,199 villages. Regarding these latter, it is as well to explain that although the Census Report shows that there are in the Presidency 167 towns each containing 5,000 inhabitants or more, yet in our tables only 55 towns have been selected as urban registration circles, the statistics of the remaining 112 towns are necessarily included in the rural circles to which they belong and are classed as villages. Out of the entire population of the Presidency (16,454,414) 4,839,007 persons or 29·41 per cent. were living in the affected districts. Of these 37,954 or 7·8 per 1,000 died. Out of 24,536 inhabited villages in the affected districts, 3,199 or only 13 per cent. were affected with cholera.

Small-pox.

During 1883 small-pox prevailed in an epidemic form more or less throughout the Presidency, and 6,895 males and 6,509 females fell victims to it. The total deaths amounted to 13,404 against 1,630 in 1882, the decennial mean being 6,522. Small-pox thus caused 3·18 per cent. of the total mortality of the year.

The number of recorded deaths from small-pox increased from 539 (the lowest number attained since registration commenced) in 1881 to 1,630 during 1882. In fact the epidemic of the year under report commenced in November 1882, when 201 deaths against 98 in the preceding month—October—were registered. It prevailed with increasing severity until March, when it attained its maximum intensity, 2,814 deaths having been recorded in that month. It then commenced to decline, but the disease did not die out; on the contrary, it showed signs of epidemicity at the close of the year as the deaths rose in December to 1,033 or 640 above the decennial mean of that month. The minimum mortality, as a rule, occurs in the month of October, but the setting in of the cold weather appears to favour the development of the poison, and it rapidly becomes more intense until March, when it usually commences to abate.

By districts the highest ratio per 1,000 of population (2·18) took place in Surat against 0·15 in the previous year and the decennial mean of 0·63. The next highest ratios occurred in Kándeish 1·90, Bombay City 1·85, Thána 1·82, Poona 1·36, and Kaládgi 1·02. The only district from which no deaths from small-pox were reported was the Upper Sind Frontier—a like immunity was observed in 1882—whilst only 4 deaths were recorded in the Shikárpur Collectorate, and 13 in the Thar and Párkar District, a similar number being reported from Kaira. The death ratio from small-pox during 1883 was lower than the mean in Sholápur, Kánara, Kaira, Panch Mahals, Ahmédabad, and Shikarpur districts.

In the following table the deaths are shown by age and months, the latter being contrasted with the corresponding months of 1882 and with the previous five years. In 1883, 33·9 per cent. of these deaths occurred among infants under one year of age, whilst 51·9 per cent. took place among children over 1 and under 12, the remaining 14·2 per cent. being among persons over that age:—

		January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
Total deaths from small-pox in each month	(5 years' mean	153	205	331	283	213	146	100	49	40	34	54	135	1,743
	1882	41	46	66	107	120	146	146	28	61	98	201	470	1,630
	1883	1,039	1,947	2,814	2,228	1,296	830	616	400	333	302	446	1,033	13,404
Deaths under 1 year	(5 years' mean	43	70	116	98	66	38	18	10	9	8	9	26	395
	1882	15	7	14	25	25	19	23	17	18	21	31	96	311
	1883	342	655	992	795	459	265	218	103	122	105	138	319	4,544
Above 1 and under 12 years	(5 years' mean	68	95	164	136	94	60	40	19	13	9	10	56	773
	1882	14	10	21	36	40	58	39	29	22	20	63	203	555
	1883	581	1,069	1,578	1,139	672	352	248	221	196	143	190	476	6,965
Above 12 years	(5 years' mean	42	40	51	60	53	48	42	20	18	17	26	53	470
	1882	12	28	21	46	55	71	98	52	41	57	107	180	758
	1883	116	223	240	244	185	180	155	71	65	36	118	238	1,900

In towns especially there is a large number of persons, chiefly young children, who are unprotected by vaccination against small-pox. I think a general feeling is gaining ground that the time is fast approaching when it will be desirable to make vaccination compulsory throughout the Presidency. If it were so there is no doubt that the death-rate would in epidemic seasons be considerably lower than it has hitherto been.

Fever.

During 1883, the deaths of 140,015 males and 126,726 females, or a total of 266,741 persons, were ascribed to fever. In 1882, 243,454 persons were said to have died from this cause. The increase therefore for the year under report as compared with 1882 amounted to 23,287 deaths, the mean for the previous 10 years being 255,531.

By districts the Collectorate of Kándeish heads the list with a millesimal rate of 24·71 against 17·65 in 1882 and 15·82 in the previous 10 years, and the following districts have exceptionally high rates: Broach 23·12, Surat 22·27, Násik 21·12, Ahmednagar 20·27, Kaira 20·09, Thána 19·24, Sholápur 18·71, and Ahmedabad 18·55. The minimum rate (7·47) was reported from Bombay City, and the following districts have comparatively low ratios: Ratnágiri 8·42, Upper Sind Frontier 8·47, Karáchi 10·75, Belgaum 11·07, and Dhárwár 11·71.

In speaking of fevers in Sind, Dr. Peacocke, the Acting Deputy Sanitary Commissioner, makes the following appropriate remarks, with which I concur:—

"In 1881, the total deaths from all causes were 31,914, of which 27,575 were from fevers.

In 1882	-	42,337	do.	37,785	do.
In 1883	-	36,582	do.	31,558	do.

"This enormous ratio of deaths from fevers is very remarkable, and the unfavourable "pre-eminence of 1882 is worthy of notice. To the inquiries made at the larger towns and "dispensaries I have been told that 1883 was much less unhealthy than 1882. This "statement is we see fully justified by the returns, which, however unreliable in themselves "as to accurate information, are yet useful in so far as they support mere statements.

"It must be gathered that fevers are the greatest cause of mortality in Sind, and a few "words on its causes will not be without interest. The chief cause may no doubt be found "in flooding of the country by the River Indus. The inundation of 1882 stands unrivalled. "Vast tracts of land in certain districts were covered four months with the water which "overflowed from the canals. These districts became very unhealthy, and severe fevers, "resulting in a largely increased death-rate, followed. The Shikárpur District was perhaps "that most severely affected, and although the death-rate of 1883 does not compare "favourably with that of 1881 (although the country was free from flooding in 1883), I "believe the increase in the number of deaths in 1883 over 1881 must be in a great measure "attributed to latent disease induced by the malarious influences of 1882. I have made "these few observations more especially in connection with my statement of last year that "the greatly increased mortality from fevers in the Shikárpur District in 1882 was due to "the inundation, and also in confirmation of the opinion expressed in my report No. 126 of "the 18th February 1883 as to whether irrigation from canals was conducive of malarious "fevers."

Bowel complaints.

During 1883, bowel complaints caused the deaths of 19,394 males and of 15,898 females, or a total of 35,292 persons against 28,353 deaths in 1882 and a decennial mean of 33,150. The North Deccan Registration Division heads the list with the very high ratio of 3·36 per 1,000 against 2·27 in 1882 and 2·41, the decennial mean. Following it comes the Southern Deccan with a ratio of 3·17, and next to it is Gujarat 2·09, after which is the Konkan 1·03, and the least of all Sind 0·21, the rate in this division being less than in 1882, 0·24, but slightly above the decennial mean, 0·20. In the Presidency the rate was 2·14 per 1,000 against 1·72 in 1882 and 2·04, the decennial mean.

Injuries.

During 1883, 3,436 males and 2,542 females, or a total of 5,978 persons, met with violent deaths. The mortality from these causes is slightly in excess of that in 1882 when 5,913 deaths were recorded. Of the 5,978 deaths 2,713 were caused by drowning, 1,215 resulted from snake-bites, 355 from wounds, 179 by hanging, 130 by poisoning, 95 from attacks by wild beasts, and 1,291 from causes not specified.

Other causes.

The recorded deaths from causes other than those specified, numbered 60,829, of whom 31,513 occurred among males, and 29,316 among females. The total for 1882 was 56,164, so for this year there is an increase of 4,665.

In concluding this section of the report on the chief diseases, I would desire to point out that great and terrible as the mortality from cholera during the year 1883 was, as by it alone 37,954 deaths were caused, yet that fevers were more than seven times as deadly, as from them no less than 266,741 persons, more than a quarter of a million human beings, lost their lives.

Cholera, from the rapidity with which it destroys, is more appalling to the popular mind, but fever is the cause of a far higher mortality.

The measures which are necessary to lessen the direful effects from these two causes are those which have been brought so frequently and so prominently to notice by the Army Sanitary Commission; the improvement of the water-supply and the cleaning of the

surface, and the drying and aration of the subsoil of the inhabited areas throughout the Presidency.

Government has sanctioned standard plans for barracks, latrines, &c., but it seems to me that above all is required a standard plan for wells. The following is the description of a well, as it should be, by the Army Sanitary Commission :—"Where a cesspit has been close "to the house well, it would be better to fill the well up with clean earth, and dig another "as far as possible from the site of the cesspit. All new wells should be cased outside "with clay or cement, or with concrete, to a sufficient depth to cut off the surface or subsoil "water from the well.

"The well is dug and built up in the usual way, but when it comes within 8 or 10 feet "of the surface the tube must be coated outside with puddle or concrete, to cut off the upper "portion of the water. The tube of the well should be carried two feet above the ground "level, and covered with a roof; the ground round the well should also be coated with "concrete, and sloped away from the well to open channels. With these precautions, which "are not difficult to take, and not costly, any well within a compound, except in very foul "ground, would yield wholesome water."

I would hope that Government will be pleased to direct increased attention to be paid to the conservation of all sources of water-supply, both in towns and villages, throughout the Presidency, and especially that no new well, the water of which is to be used for drinking, shall be constructed except on the plan recommended by the Army Sanitary Commission.

I also hope that measures may be taken to improve the quality of the water in those towns, which are dependent solely on rivers for their supply. In some such in Gujarát and in the south it is possible to dig wells on the river banks; and this course would probably be the best to adopt, but over great parts of this Presidency this action would do no good because the river bed is formed on the hard trap rock, and there would be no filtration through the soil, but it seems to me some rough means of filtration might be adopted. Whether in small rivers by building during the fine season a thick wall of sand across the bed, or part of the bed, or by digging reservoirs on the side and making the water passing into them, filter through a thick layer of sand, or as suggested by Mr. McLaren, R.E., by having walls holding a filtering medium made in the bed of the river from which the people could draw water during the fine season. But in drawing attention to the subject, I desire to point out, in the strongest way I can, the great danger of drinking river water, which has received the impurities of villages situated further up its course.

The decreased mortality from cholera in Bombay and in other cities where a pure water-supply has been introduced, is a convincing proof that it is the first great line of defence against cholera.

The geological formation of the greater portion of the Presidency forbids the hope that artesian wells would be of any service in most of the districts; but in Gujarát, perhaps, they might be tried with a probability of success, which, if attained, would solve one of the most difficult problems in that part of the country.

The people, however, are too poor to make the experiment; but I would hope that Government will be pleased to devote a portion of the public funds for the purpose of experiment.

The one great cause of fever throughout India is the existence of dampness in an impure and foul surface and subsoil in inhabited areas. I by no means forget the general malarious character of many parts of the country, but I am certain that most of the disease in India is due to local insanitary conditions around and in the midst of the habitations of the people.

It is clear that sanitation must begin at the houses of the people before any great reduction in the death-rate can be looked for. It cannot, however, be carried on without a constant and heavy expenditure. Government gives a special allowance for education, and I would respectfully venture to express my opinion that the preservation of health is as great a boon to the masses as the culture of the mind. It may be said, that as education spreads, the people will be led to see the great calamities they suffer from by such a heavy mortality taking place year by year in their midst, and gradually see the necessity for taking measures to prevent it. That is very true, but when I see that no less than 170,327 children were in a single year cut off before they had attained their fifth year of life, I should fail in my duty if I did not ask Government to provide in some way for the removal of the insanitary conditions to which these deaths are due.

I believe if the object were properly explained to them, the people of India would readily submit to a special tax for sanitary improvement, *if only the money so collected, were spent in the improvement of each individual village from which it were received.* The people of India are by instinct a cleanly race; they wish to be clean, but they have no idea of united

action so as to carry out those structural works by which alone, for example, the subsoil can be dried, or water after domestic use be removed to a distance from habitations.

I believe that the leaders of native thought would support the introduction of such a tax, for there is no measure which would conduce more materially to the real and permanent welfare of their countrymen, or would save an amount of human misery which it is perfectly lamentable to contemplate.

Vaccination.

The following table contrasts the work amongst the civil and military population during the year under report with that for 1882–83 :—

Establishment.	Persons primarily vaccinated.				Persons re-vaccinated.				Total Number of Persons operated on.			
	1882-83.	1883-84.	Increase.	Decrease.	1882-83.	1883-84.	Increase.	Decrease.	1882-83.	1883-84.	Increase.	Decrease
IN CIVIL LIFE.												
Itinerant	758,047	792,784	34,737 (4·45)	—	59,947	59,494	—	9,453 (15·78)	817,994	843,278	25,284 (3·09)	—
Dispensary	28,770	29,986	1,216 (4·23)	—	2,435	2,525	90 (3·70)	—	31,205	32,511	1,306 (4·19)	—
Total	786,817	822,770	35,953 (4·57)	—	62,382	53,019	90 (0·14)	9,453 (15·15)	849,199	875,789	26,590 (3·13)	—
IN ARMY LIFE.												
Native Army	4,987	3,698	—	1,289 (25·85)	3,581	2,846	—	735 (20·52)	8,568	6,544	—	2,024 (23·63)
British Army	402	497	95 (23·63)	—	542	1,009	467 (86·16)	—	944	1,506	562 (59·53)	—
Total	5,389	4,195	95 (1·76)	1,289 (23·92)	4,123	3,855	467 (11·33)	735 (17·83)	9,512	8,050	562 (5·98)	2,024 (21·28)
Total for the whole Presidency.	792,206	826,965	36,048 (4·55)	1,289 (0·16)	66,505	56,874	557 (0·84)	10,188 (15·32)	858,711	883,839	27,152 (3·16)	2,024 (0·24)

It will be observed that there were 826,965 persons primarily vaccinated, and 56,874 re-vaccinated, against 792,206 and 66,505 in 1882–83, showing a net increase of 34,759, or 4·39 per cent., under primary vaccinations, and a net decrease of 9,631, or 14·48 per cent., under re-vaccinations. There was a considerable decrease (23·62 per cent.) under total operations amongst Native troops, the figures being 6,544 against 8,568 in the preceding year. The rate of increase in re-vaccinations was only 0·84 per cent., but it was very high amongst European troops, being 86·16 per cent. On the whole, there has been an increase of 25,128 or, in other words, for every 100 persons operated on in 1882–83 the numbers for this year have been 102·92.

Out of 826,965 persons primarily vaccinated, 791,323 cases were successful, or 95·69 per cent. or 0·46 per cent. below 1882–83. The number of unsuccessful cases were in excess of that in the preceding year, being 17,363 against 14,232. 2,433 persons were operated on a second time on account of the failure of the first operation, and in 20,712 cases the result is unknown, as the children were not again brought for inspection.

During the year, 56,874 persons were re-vaccinated against 66,505 for 1882–83. In 129 instances the re-vaccinations were repeated, in 6,289 instances the results could not be ascertained, and in 13,057 the operation failed. The number of successful cases was 37,657, or 66·21 per cent. against 69·80 in the preceding year.

The total number of persons operated on was 883,839, and of these 828,980, or 93·79 per cent., were successful. In 1882–83 the percentage was 94·11. There were 2,562 persons operated on more than once; the "unsuccessful" numbered 30,420, and the "unknown" cases were 27,001.

The age details are compiled for three periods, viz., under 1 year, between 1 and 6 years, and above 6 years. The number under each period primarily vaccinated were respectively 504,282, 298,582 and 24,101 against 485,661, 284,141 and 22,404 during the preceding year. The number of infants successfully vaccinated was 484,405, of children between 1 and 6 years 285,172, and of persons of other ages 21,746. Thus, out of every 100 persons primarily vaccinated, there were 60·98 infants, of whom 58·58 were successfully vaccinated. When compared with the preceding year, it is, however, lower by 0·57; but this is only apparent, because the difference between the numbers vaccinated and the successful cases is higher by 0·15 per cent.

The rate of protection was higher than last year in all the districts and circles, except in Cutch, Northern Deccan, Presidency Circle and Konkan. It was lowest in the Konkan and Presidency Circle. In British and Native territory it was respectively 30·57 and 31·49 against 29·89 and 29·46 per 1,000 of population in the previous year. On the whole, 30·89

persons of all ages per every 1,000 of population, against 29·74 last year, 27·54 in 1881–82, 24·60 in 1880–81, and 22·26 in 1879–80, were primarily vaccinated successfully.

Animal vaccination was carried on in Bombay, Poona City and Cantonment, Broach, and Kaira Collectorates and Rájkot and Dhrángadra. Much difficulty is experienced in obtaining heifers for inoculation. The Bombay method of advertising for a constant supply of heifers by contract was tried, but failed; consequently animal vaccination had to be stopped in the towns of Broach and Nadiád. Animal vaccination is popular among villagers, as it saves them the trouble of taking their children from village to village.

Except in Bombay, where animal lymph only is used, and in Poona, Broach, Nadiád, Anklesvar, Borsad, Rájkot and Dhrángadra, where both animal and human lymph were in use, vaccination in all other places was carried on from arm to arm and with human lymph. Vaccination with animal lymph was also carried on in Bándra. The total number of heifers inoculated was 935 against 645 last year; in 84 the virus did not take.

The total cost for the whole Presidency, including all charges, was Rs. 2,69,738.9.0, whilst the successful cases, excluding dispensaries and the army, amounted to 794,380. The average cost per each successful case was annas 5.5., or 2 pies less than last year.

There were 31 Inspectors and four Assistant Superintendents on travelling duty. Of this number 27 Inspectors and two Assistant Superintendents were paid by Government, and the remainder by Native States. The names of 364,063 children were called from the registers, of whom 276,212 were present, 87,853 were absent, but their absence was accounted for, whilst 98 could not be accounted for, as they had migrated. Out of 276,212 children inspected, 265,460, or 96·11 per cent., were protected, and in 10,752 cases, or 3·89 per cent., the operation was unsuccessful. Again out of 265,460, or 96·11 per cent. successful cases, 186,434 or 67·50 per 100 had "good" cicatrices, 51,604 or 18·68 "middling," and 27,422 or 9·93 "bad." In the registers tested, the results were entered as 341,904 successful, 12,705 unsuccessful, 10,176 unknown or absent, and 722 secondary operations. Excluding the unknown and secondary operations from calculation, to compare this result with that of inspection, the percentages of successful and unsuccessful cases are respectively 96·61 and 3·39. This shows that the results recorded by the vaccinators are approximately correct. The rate of travelling was quicker than last year in the Southern Deccan, Konkan, Eastern Gujarát, Sind and Baroda, and the number of villages seen was greater in Cutch and Baroda. The greatest number of villages seen was in Sind. The number of children inspected was greater in two districts and two circles—viz., the Northern and Southern Deccan, Cutch and Baroda.

Taking the work of all the Deputy Sanitary Commissioners, Superintendents, Assistant Superintendents, and Inspectors together, there were 4,417 encampments, 81,886 miles travelled in 8,136 days, and 360,271 children inspected in 12,989 villages. Out of every 100 persons operated on, 40·76 were this year inspected against 41·20 in the preceding year.

The Compulsory Vaccination Act (I. of 1877) has been in force for five years, and it is worked fairly well. The number of infants protected during the year was 12,331 against 14,940 in 1882–83. The decrease in 1883–84 is partly attributable to the large number of vaccinations owing to the prevalence of an epidemic of small-pox during the previous year.

This is the fourth complete year in which the Karáchi Vaccination Act (No. IV. of 1879) has been worked in that city, and a great improvement has been effected in the number of infants protected.

The Superintendent of Vaccination, Western Gujarát Circle, says that "revaccination has "made a great stride. This is entirely due to the fact that I take down all the names of "unprotected children requiring reprotection in every village and town I visit and give "them to the vaccinators. The parents then seldom refuse. I have also called upon the "Assistant Superintendents to act accordingly. To this I also attribute the large increase in "primary vaccinations."

He has also addressed a circular to the Political officers requesting them "to use their "influence with Native States to insist upon their dispensaries," which are 65 in number, "keeping up lymph so as to be able to give it to vaccinators on the appearance of an "epidemic near head-quarters."

The Chiefs of Káthiáwár have sanctioned the entertainment of a female vaccinator. An educated woman is now learning the art of vaccination, and when she has acquired that knowledge she will visit the courts of all the Chiefs.

Sanitary Works.

The actual outlay on sanitary works (military) during 1883 amounted to Rs. 1,74,733; of this sum Rs. 95,885 were expended at Jacobabad for constructing new Native Infantry lines. At Ahmedabad Rs. 34,580 were spent, of which Rs. 34,262 were for constructing Military works.

a hospital for British troops. At Nasirabad Rs. 21,338 were expended, of which Rs. 5,049 were for constructing new open drains in the Sadar Bázár, and Rs. 2,522 for renewing floors and cleaning walls of Royal Artillery stables. At Mhow Rs. 4,275 were spent, of which Rs. 699 were for excavating floor and removing soil of the sick horse stables of 17th Lancers, Rs. 861 on stable No. 16 occupied by A Troop 17th Lancers, and Rs. 1,528 were spent on stable No. 18 after a case of Loodhiana fever. At Poona Rs. 4,164 were spent, of which Rs. 2,097 were for converting the block of six cells into isolated wards for the station hospital, and Rs. 1,663 for preserving and watering trees that have been planted in connection with sanitary improvements to Ghorpuri Barracks.

Civil works.

The total annual income of the 163 municipalities during the year 1882–83 was Rs. 27,10,952, and the sum expended on conservancy by them was Rs. 11,48,903.

The details of the sanitary condition of the municipal towns given in the Sanitary Commissioners' Report are not reprinted.

ABSTRACT OF REPORT OF THE MADRAS MUNICIPALITY FOR 1884.

(*Mr. A. T. Arundel.*)

Drainage.

The pump and engine-house at Royapuram, the outfall channel with a masonry weir, and sewer No. 3 were practically completed during the year. The grant of the site of the engine-house &c., was confirmed to the municipality rent-free by the Government of India (G. O., No. 64 Revenue dated 16th January 1883). Sewer No. 3 is one of the main sewers of the new drainage system. It is 2,498 feet long and extends from the engine-house to the harbour intercepting sewer.

In connection with the general scheme, 11¼ miles of surface drains of various sizes were constructed. New house drains to the number of 314 were constructed by the owners themselves, and 21 by the municipality. A good deal more remains to be done in this direction. Advantage was taken of the works in progress to remove obstructive projections and encroachments in the streets, and to raise the level of many of the streets. Compensation had to be paid for removal of some of the old standing encroachments; but all these claims have been settled without serious difficulty or resort to law. The backyard floors of several houses which were below the level of the new drains have been raised. The total amount expended on drainage during the year was Rs. 1,64,351.0.10. In 1882 the amount spent was Rs. 78,921.7.5. The total expenditure up to end of 1883 was thus Rs. 2,43,272.8.3 out of an available sum of Rs. 4,00,000 raised by loan for the purpose. There remained a balance of Rs. 1,56,727.7.9 out of the loans for expenditure in 1884.

The diversion from the Coovum of the contents of the large sewer near Government House Bridge was nearly completed during the year. The engines and pumps were in course of erection when the year closed.

Water supply.

The extension of the water supply throughout Madras commenced in 1882 was completed during the year. Twenty-eight miles of pipes of various sizes, 170 valves, 463 hydrants, 178 fountains, and 27 silt traps were fixed. The cost of extension during 1883 was Rs. 1,65,436.9.3, which, together with the expenditure in 1882, made a total of Rs. 2,62,843.6.2 or Rs. 12,843.6.2 in excess of the loan raised in 1882 for the work. The balance was met out of the General Fund. Four miles of pipes, 31 fountains, 56 valves, and 24 silt traps, were fixed over and above the number contemplated in the original extension scheme. These extensions have naturally diminished the head of water available for general supply, and complaints are made that in some localities the house services are nearly useless. It is found moreover that some additional extensions are urgently necessary to a few outlying tracts still in need of water and also to erect additional fountains in localities only partially supplied. These additions must be considered in connection with a forthcoming scheme for an increase in the supply of water to the town and for its thorough purification by filtration.

The supply from the Red Hills Lake was maintained throughout the year, except on the 5th and 6th September 1883, when the supply to the 4th, 5th, 6th, 7th and 8th divisions was shut off to enable a 14" scour pipe to be fixed at the junction of Purasavakum High Road and Brick Kiln Road. During this time the town divisions were supplied from the Trevelyan Basin. The lowest level at which the lake stood was 36·21 in October 1883, when about 22½ inches of rain fell and raised the level. There were two slips in the Delivery Channel bund of a dangerous nature caused by the heavy rains; these were promptly repaired. The quantity of water drawn off from the lake into the Delivery Channel was 50,89,426 cubic yards for which Rs. 5,089.6.10, has to be paid to Government at the rate of R. 1 per 1,000 cubic yards. Proposals have been made to secure the conservancy of the shores of the Red Hills Lake, and powers have been inserted for this purpose in the new Municipal Act.

Conservancy.

In the removal of rubbish and filth 1,155 coolies, 586 carts, and 4 canal barges were employed; 363,328 cart loads were removed besides about 30,181 tons of night soil. The cost of hire of bullocks was Rs. 96,208.6.4. In the cleaning of main drains an expenditure of Rs. 7105.6.5 was incurred, but this sum includes arrear of 1882 on account of Black Town main drain.

Vaccination.

The expenditure on vaccination was Rs. 5,601.8.0 against Rs. 5,209.3.7 in 1882. The total number of cases vaccinated was 40,940 against 28,030 in 1882. The increase was

abnormal and was due to an unusually severe outbreak of small-pox which induced the people to resort to vaccination. The successful cases were 37,138, the unsuccessful 2,043, while 1,759 were not traced. The ratio of successful cases to the total vaccinated was 90·7 against 89·7 in 1882, and of unsuccessful cases 5·0 against 6·0 in 1882. The number of infants under one year vaccinated was 14,165 against 8,968 in 1882 or 88 children for every 100 born in 1883 against 54 in the previous year. The course of the epidemic will be traced in the report for 1884.

Health of Madras.

The birth-rate per 1,000 was 41·2 as compared with 42·7 in 1882, 40·3 in 1881, and 40·4 in 1880. The total number of births was 16,464 against 16,991 in 1882. The percentage of male births to female was 51·3 to 48·7. Of the births registered 395 were still-born, or for every 100 children born 97·6 represent "born alive" and 2·4 still-born.

The death-rate was 39·8 as compared with 35·6 in 1882, and 38·9 in 1881. The total number of deaths was 15,882 exceeding those of 1882 by 1,713. It is below the average of 10 previous years by 823. The cause was the prevalence of small-pox of a severe type.

The deaths were:—

	1882.	1883.	Increase.	Decrease.
Small-pox - - -	355	1,957	1,602	—
Measles - - - -	148	138	—	10
Fevers - - -	3,706	3,470	—	236
Cholera - - - -	461	169	—	292
Bowel complaints - -	2,110	2,284	174	—
Other diseases - - -	7,389	7,864	475	—
Total -	14,169	15,882	2,251	538

ABSTRACT OF REPORT OF THE MUNICIPAL COMMISSIONER FOR THE CITY OF BOMBAY FOR 1883—84.

(E. C. K. Ollivant, Municipal Commissioner.)

Water supply.

Of the works relating to water supply, those specially deserving of notice are the measures proposed and now in progress for increasing the quantity of water obtainable from the Vehar and Tulsi Lakes. When the Budget for the year under report was being considered, I addressed the Town Council on the subject with the result that the proposals then made were adopted, and that the Corporation upon the recommendation of the Town Council resolved on the 16th May 1883 that application should be made to Government for sanction to raise a loan of Rs. 20,88,000, by which provision was to be made for the works (amongst others) to which I now refer. The sanction of the Government of India to the proposed loan was communicated on the 18th January 1884.

Before the close of the financial year not only had the detailed surveys been completed, but considerable progress had been made with the catchwater channels, both at Vehar and Tulsi. The former promised to be effective for the ensuing season, the completion of the latter entailing rock and masonry work would, of necessity, require a longer period, but there is every reason to believe that they will be serviceable for the monsoon of 1885, by which time also it is to be hoped that the dams of the Tulsi Lake may be raised to the additional height proposed. The laying of the new main (for which a contract has recently been let) will occupy two seasons; but the half that is expected to be ready by April next (which will be connected with the existing main at Kurla) will confer an appreciable benefit in the next hot season. With reference to the Tulsi dams I may mention that the expediency of making the previous increase to the height (6 ft.) was well established by the experience of the present year, as the height of water in the lake on the 31st March was 6 ft. over the level of the old waste weir, and consequently not only was a larger supply available but the water was purer in quality—the draw-off being at a higher level than in any previous year.

The progress of work at the two reservoirs was not satisfactory, the completion of the contract work in both cases having been delayed long over contract time. The only work in hand at the Malabar Hill Reservoir was the construction of the filter beds, and these, though not ready for working within the year, were complete according to the design before the end of the hot season. The roofing—which will form the subject of a separate contract—has still to be done. The John Hay Grant Reservoir* at Bhandarwada Hill is now virtually complete, but it is very doubtful whether it can do full duty until the new main has been laid from Vehar. The work of laying the new mains (48″ and 32″) and making the several junctions in connection with this reservoir was attended with considerable difficulty, and the waterworks staff rendered excellent service in carrying it through.

The new main laid in Dungri Koli Street was much needed to give a better supply to that crowded section of the city, especially in cases of fire. During the year, 71,987 feet of old mains were examined by the waste water prevention staff, and wastage to the extent of 384,000 gallons per diem was discovered and rectified. I propose as soon as possible to introduce the Deacon Meter system for the prevention of waste, which has been found to answer so well in Liverpool, Glasgow, and other towns; and with the sanction of the Corporation, provision has already been made for the purpose in the loan already alluded to.

During the year, 437 new connections were granted, the total number now being 13,681; of properties so supplied, 12,737 pay by rate, 785 by meter, and 159 by special terms.

Drainage.

Very good progress was made during the year with the large intercepting sewer designed to carry the storm waters from Gowalia Tank and Khambala Hill to the old open main drain on the Flats. The rainfall of that neighbourhood will no longer contribute to the flooding of Khetwadi: the monsoon of 1883 showed that the measures already carried out in that neighbourhood (Khetwadi) had by the raising of low lands and the construction of three rain water sewers produced a marked beneficial effect. But though these local sewers and the large intercepting sewer already spoken of will do much to mitigate the long-standing evil, nothing like a complete remedy can be looked for (at times when a very

* In this reservoir the filtered water alone is roofed; in the Malabar Hill Reservoir the whole area of the reservoir is to be roofed, unfiltered water and filter beds included.

heavy rainfall happens to be coincident with neap tides) until the other large intercepting sewer to the east, and the storm water reservoir on the Flats have been completed. The completion of the latter sewer will still occupy another year. The waters from Pydhoni and districts eastward of the Parel Road being carried direct to the Flats will then no longer prevent the floods of Khetwadi from finding an exit in the direction of Falkland Road. There is nothing to delay the completion of the reservoir on the Flats save the diversion of the Tulsi Pipe Line. The greater part of the new main has been laid, and when the old main has been taken up, the reservoir work will be proceeded with. If funds allow, it will be desirable to make it at once of the size originally recommended by the consulting engineer (200 acres), instead of confining it to the 136 acres now contemplated. Measures should also be undertaken as soon as possible for the relief of the more suburban districts from floods, especially as buildings are being rapidly extended over ground which a few years ago was swamp or ricefield.

But in order to make any satisfactory arrangement for the disposal of storm water, at any rate from the more populous parts of the city, it is absolutely necessary that the disposal of sewage should not be ignored. The two things must be considered together. Local conditions render it impossible that a heavy fall of rain should be passed off rapidly when tides are high. It must therefore either be led to a temporary resting place where it will do as little harm as possible until it can obtain outlet to the sea, or it must be got rid of by pumping. The latter alternative was estimated by the late Mr. Ormiston at a cost that makes it prohibitive, the former alternative is the one which has been adopted. But it is very evident that the channel which conveys the rain water to the reservoir should not also be a carrier of sewage. Yet so it is, and this sewage pollutes the channel to an indescribable degree, and pollutes the Flats on to which the channel overflows and will pollute the reservoir (though not quite to the same extent, for periodical cleansing will be feasible). In past years there has been no help for this, but now that a thoroughly good sewage carrying sewer leading to the new pumping station has been constructed, there will be no excuse for allowing the intolerable nuisance to continue. Yet it must continue until all the sinks, gullies and cesspools of the city are connected with the new sewers instead of the old sewers which also carry rain water in the monsoon and discharge on to the Flats.

The new pumping station was fitted with its full complement of engines and has been found so far to answer admirably. The machinery is calculated to accommodate the whole of the sewage of that portion of the island to which the Report of the Drainage Commission of 1877 applied. The old pumping station with its outfall into the Love Grove channel was finally abandoned, and the municipality were after 14½ years freed from the liability of paying Rs. 300 per mensem on account of the nuisance caused by that outfall. The erection of a covered chamber and kiln for the disposal of the refuse collected at the point where the main sewer reaches the pumping station, is much needed.

The intercepting sewer (known as the Queen's Road sewer) designed to prevent the discharge of sewage into Back Bay was in course of construction the whole of the year. The early progress was good, but after the monsoon, when the work became more difficult, it was not satisfactory. So great was the sewage nuisance on Back Bay in the early part of 1883 that the Corporation offered a bonus of Rs. 10,000 if the contractor would in return undertake to complete the sewer by the commencement of the monsoon of 1884 instead of in February 1885, the contract time, and this he agreed to do. This agreement was entered into on the 1st February 1884. The month of March had hardly expired when the contractor threw up the work, and I had to make arrangements for carrying it out departmentally. This was done under the executive engineer, Mr. Walton, and the energy with which the work was brought to a conclusion by the end of June reflects the greatest credit upon him and the staff employed under him. In alluding to the completion of the work, I am, strictly speaking, going beyond the limits of the year under review, but this brief reference seemed to be desirable.

The new ovoid sewer in Clerk Road to the Six Roads Junction was completed, and a further extension to the Victoria Gardens was sanctioned and commenced before the close of the year. This main sewer will serve the branch sewers which are to be laid from the gas works and Parel on the one side, and from Byculla and Clare Road on the other. Provision for these works was made in the new loan already alluded to, and contracts were let in March. This district, in which fresh buildings are constantly springing up, has hitherto been undrained, and has been the subject of frequent complaints. Similar arrangements were made with regard to a new ovoid sewer from the Mint to the Crawford Market, by which the sewage of the Fort and of the southern portion of the Port Trust Estate, hitherto discharged into the harbour, will be conducted to the new pumping station at Love Grove. But, during the monsoon, the sewage of the Fort must, until separate branch sewers are provided for the segregation of sewage from storm water, continue as heretofore to find an

outlet into the harbour. So, too, on the western side of the city from the Secretariat to Chaupati, notwithstanding the Queen's Road intercepting sewer, the continuance of the numerous sewage outfalls into Back Bay is subject to the same conditions. Careful surveys were made of the sewerage of the Fort. The condition of most of the existing sewers is as bad as it can be, and plans were prepared for a complete new system estimated to cost Rs. 4,53,329. The execution of this work should not be delayed. Together with the sewerage of Nagpada, so repeatedly brought into prominent notice by the Health Officer, and of the districts immediately abutting on the Queen's Road, it merits the earliest possible consideration of the Corporation.

The pipe sewerage of Kamathipura was completed, and tenders were invited for the supply of iron materials for house connections there and in the first drainage section (comprising Market, Mandin, Umarkhari, and parts of Buleshwar, Khetwadi, and Girgan), and for the execution of the work of laying and fixing them. No tender for the work was received; subsequently one firm of contractors made an offer on terms too high to be entertained. For the supply of iron work for Kamathipura only a tender was eventually accepted on the 13th March 1884. The work will be proceeded with as soon as the materials are received. All other house connection work is in abeyance, pending the further sanction of the Corporation. I have had occasion to notice that much greater difficulties attend the use of syphons in this country than in England, and I have suggested the alternative course in certain cases of connecting the house gullies, instead of the individual houses, with the new sewers. The great object to achieve for the sanitary improvement of the city is to carry off polluted water or house sullage by means of the new sewers, and to do this it is absolutely necessary that a mode of ingress inaccessible to storm waters, or, in other words, above the ground level, should be secured. Until this is done, most of the new sewers are practically useless, and the evils, for the removal of which they were designed, continue unabated. Old house connections, where they exist in many parts of the city, are generally in a most deplorable condition, and so are the drains into which they discharge.

LIBRARY OF THE BOMBAY BRANCH OF THE ROYAL ASIATIC SOCIETY

ABSTRACT OF REPORT OF THE HEALTH OFFICER OF BOMBAY FOR 1883.

Public health.

During a considerable portion of the period under review, the health of the city was not good. There were 3,062 deaths more than in the previous year, and 931 more than the average of the previous five years. The gravity of this large increase is not lessened when we reflect that it was mainly due to the most prominent of what are termed preventible diseases, chiefly cholera and small-pox; but the mortality from fevers was 1,656 less than the average, it is right to mention.

Exclusive of still-born, 23,530 deaths were registered. The death-rate, estimating for increase of population, is equal to 29·12 per 1,000, as compared with 25·89 in 1882. The death-rate amongst a large permanent and non-fluctuating class of the population, the Parsis, is but 22·96.

In each of the four quarterly reports for the past year, I have brought forward, in the most urgent manner, the absolute necessity that exists for a permanent hospital for infectious diseases, and the municipal commissioner, in a letter published in the local newspapers, called attention to the want of an institution of this description. The necessity, however, for a permanent epidemic hospital must be so apparent to every one that it would be useless to add more on the subject. Now that this most important and pressing want has been brought again so prominently to their notice, there can be no doubt that the municipality will, without delay, sanction the necessary expenditure in order to provide this ordinary and necessary means of precaution for dealing with epidemic diseases.

Progress in sanitary work.

I would beg to draw attention to the extreme desirability of increasing the working establishment of this department. The scavenging branch is inadequate for the requirements of the city which cannot be kept in a completely clean, healthy, and sanitary condition without the increase which I have elsewhere asked for. The number of bullocks should be augmented. They are too few in number, and get quickly worn out, owing to their powers being overtaxed, thus entailing a pecuniary loss upon the municipality, while the work is not thoroughly done.

The question of the disposal of town sweepings has lately given rise to much discussion, but as it has been agreed to by all parties that under no circumstances will it be possible to continue to deposit cutchra on the Flats for any length of time, it is unnecessary to enter into any discussion in regard to that matter beyond expressing a decided opinion on my part that, under no circumstances whatever, should the present system of removing sweepings to the Flats be continued one day longer than is absolutely necessary. Some experiments have been made in burning cutchra, the results of which have only gone to strengthen the opinion previously entertained that this means of getting rid of the sweepings would, during the rains, prove a financial failure. The proposal to carry them out to sea would, during the monsoon, be attended with risk, so that the only other alternative seems to be to remove the cutchra to Kurla, and for this purpose I would again strongly advise that a tramway, which you have had under consideration for some years, should be constructed, which would in the end pay itself, and be the property of the municipality. Moreover, it will not be lost sight of that a large revenue would be realized from reclaimed land at Kurla. There would, no doubt, be some difficulty in obtaining suitable places for sidings. In certain parts of the town tanks might be filled in as originally recommended, by the Sanitary Commissioner, and used for this purpose. But whatever means of conveyance be adopted, the more the question of the disposal of cutchra is considered in all its bearings, the more desirable will its removal to Kurla appear to be. It is a simple, practicable, and, from a sanitary point of view, wholly unobjectionable solution of the difficulty.

In my Report for the 3rd quarter I have called attention to the fearful condition of the Port Trust property of Mody Bay in the following manner: "I cannot conclude this report without bringing to your notice the serious nuisance arising from the filthy condition of the foreshore at Mody Bay. To this place hundreds of people resort for natural purposes, and the night-soil is allowed to remain from week to week and month to month, without any adequate effort being made by the Port Trust to remove it. It is useless for the body to contend that there is sufficient excuse in the fact that latrines do not exist. They have not provided latrine or privy accommodation for a large number of their workmen and tenants, and until such time as they have complied with this requisition, which both decency and

health alike demand, they should be held legally responsible for the sanitary condition of their property. The breeze from the open sea sweeping over the putrefying night-soil carries infection and disease to the neighbouring European General Hospital, and many other buildings, inhabited both by Natives and Europeans. The nuisance has now reached such a pitch that it almost surpasses any other in Bombay, and immediate measures are therefore imperatively called for."

It seem preposterous that while lakhs of rupees are being spent for the removal of sewage, the Trust should permit masses of night-soil to accumulate and putrefy on the foreshore at Mody Bay, thus poisoning the air within a short distance of inhabited houses. It is absolutely necessary, in the interests of the public health, that active measures should be taken to induce the Port Trust to abate this nuisance.

The Back Bay nuisance, which had disappeared for some years, I believe, has been a source of grave anxiety during a few months of the past year, but I have already submitted a full and exhaustive report in regard to it, pointing out, amongst other things, that the Sonapur Main Drain, though one, is not the only cause of the nuisance. Every effort was made, and successfully, to mitigate it.

Much attention has been devoted to the condition of the Carnac Bandar Night-soil Depôt. The Tulsi water was at my suggestion turned on at this place, and affords generally an abundant supply with which to flush the tank. Before this, salt water and Vehar water were used for cleansing the depôt, but towards the end of 1883 the supply fell short and was not sufficient. Hoses have been provided, and new gratings made which, it is hoped, will admit of the night-soil being dropped direct through the hoppers into the tank without the intervening barrier of a grating to remove cutchra, such as rags, stones, &c. The nuisance, however, must continue to exist in a greater or less degree until such time as the night-soil is deposited elsewhere. Were a tramway constructed to convey the street sweepings out of the island, it would be a matter worthy of serious consideration whether the night-soil could not be removed by the same means.

It is a matter of congratulation, from a sanitary point of view, that the drainage of the city is being gradually, if not rapidly, proceeded with. Whether the whole of the sewage will ultimately be carried by the sewers, or whether the more highly scientific and sanitary mode of conveying by them only the sullage and subsoil water and of returning the night-soil to the land, be adopted, it is a matter for sincere congratulation that, it is to be hoped, at no very distant date the larger number of the 1,800 cesspools which are to be found scattered over Bombay will be done away with, and the disease producing subsoil water, in a measure, removed. When this has been accomplished, and a sufficient supply of wholesome drinking water provided, two of the chief causes of disease in this city will have been swept away. It is vain to hope that districts, damp and saturated with sullage which has no outlet, can be other than hot-beds of disease. It is most desirable, therefore, that the drainage system should be pushed on as quickly as possible, and every effort made to obtain a proper supply of pure drinking water for the city, and until this is done frequent epidemics of cholera and other diseases must be expected.

Vital statistics.

The mortality arranged according to groups of important death-causes is shown in the table which follows, except under measles and diseases of the respiratory system, from which there was a less mortality; there was an excess mortality from other causes over that of 1882. The death-rate from small-pox was 1·70, cholera 1·02, fevers 0·41, phthisis 0·44, diarrhœa 0·05, increased since 1882.

Causes of Death.	Number of Deaths.	Rate per 1,000 of Population.	Remarks.
Small-pox	1,461	1·81	
Measles	329	0·39	
Fever	5,903	7·31	
Cholera	1,027	1·27	
Phthisis	3,144	3·89	*Annual increment of population is calculated.
Diseases of nervous system	2,849	3·53	
Do. respiratory do.	3,394	4·20	
Diarrhœa	1,160	1·43	
Dysentery	646	0·80	
Accidents	357	0·44	
All other causes except still-born	3,270	4·05	
Total	23,530	29·12	

In 1883 we find that 10,087 children under 5 years of age died. The mortality per 1,000 of population in 1883 was 123·40, and in 1882 it was 108·99; the deaths of infants under 1 year of age in 1883 were 815 more than in 1882; the death-rate of infants under one year of age in 1883 was 290·73 per 1,000 to 254 per 1,000 in 1882. The deaths under 5 years of age were 42·46 per cent., and the deaths under 1 year 27·96 per cent. of the total deaths; in 1883 the deaths under 1 year of age were equal to 43·34 per cent. of the births. The deaths from fevers amongst children under 5 years of age were 435 more than in 1882.

Small-pox. The mortality from small-pox was very high, yet it was less than in 1876. There can be no doubt that as vaccination is more extended, and hygienic measures more carefully attended to, small-pox will, or at least ought to, become a disease of the past. But in order to protect Bombay from this scourge, it is not only necessary that vaccination should be rigidly carried out in the city itself, but also in the mofussil. A very large number of those attacked were strangers in Bombay, and in the ordinary course of things would not have been vaccinated here. A small-pox hospital is an absolute necessity, the want of which has been acutely felt in dealing with epidemics of this disease, and it is sincerely to be trusted that another year will not be permitted to pass without providing Bombay with such an institution. In all 1,461 deaths were registered from small-pox; 519 of the great number occured in March.

Cholera The cholera epidemic, properly so called, which had raged for several months from May to October 1883, had subsided, and in November there were only four deaths from the disease, and in December up to the 18th of the month six, when a sudden outbreak occurred almost coincident with the breaking of the Vehar main, which deprived Bombay of its larger source of supply of pure drinking water for three consecutive days. It has often been suggested that cholera is communicated or caused by impure drinking water, but in no instance that I know of has this surmise received more support than in the present instance. That the people, on being deprived of their ordinary supply of water, had recourse to impure wells and tanks, is undoubted. In many cases this has been clearly proved, and where the quantity of water was scantiest, there was cholera most virulent. On and in the neighbourhood of Navroji Hill, where sanitation was in the very worst state for this city, and the water supply least, cholera was most prevalent. The gullies, drains, cesspools and general surroundings of the houses were in a bad condition; many of the dwellings in which the disease broke out were badly ventilated, badly drained, and dangerously overcrowded, while imperfectly constructed, and uncleansed cesspools were to be found in various quarters. Near one house in C. Ward, where five cases occurred, the condition of the cesspools was truly appalling; they were so large and so constantly filled with a dilute solution of sewage that we, with our inadequate establishment, were unable to keep them clean. At some distance from those receptacles was a well of drinking water from which the supply for all domestic purposes was too surely drawn during the break in the Vehar water main.

With regard to Navroji Hill, the sanitary measures adopted were of a most energetic description. Extra carts were employed for removing cutchra, and additional biggaries and sweepers, under European Inspectors, entertained for properly cleansing this portion of the city. Every lane, gully, drain and privy throughout the hill was thoroughly cleansed, and the drains and gullies were freely flushed with a rough mixture of crude carbolic acid and lime. In every house in which cholera occurred the following and usual process was adopted: the floors of the rooms were dug up, and saturated with strong carbolic acid; the walls scraped and washed with phenyle, sulphur and dammer burnt in the rooms with closed doors for three days; the walls whitewashed at the expense of the municipality, the privies, drains, gullies, &c., cleansed and flushed with a mixture of carbolic acid and lime, while the privies themselves were whitewashed, and large fires with sulphur and dammer burnt in them and around the houses and along the streets. So convinced was I that impure water, consequent on the breaking of the Vehar main, was the cause of the outbreak, that at its commencement I expressed a decided opinion to that effect. I also expressed an opinion, which has been fully justified by subsequent effects, that as the outbreak in all probability was due to a local remediable cause, it would probably be of short duration and numerically not serious.

The character of the outbreak at its commencement was of a deadly type; the greater number of those attacked rapidly dying, and even in the J. J. Hospital and the Cholera Hospital at Grant Road, where everything practicable was done for the patients, the deaths largely preponderated over the recoveries. As time went on, however, the disease assumed a milder form, and recoveries were much more frequent.

The cases of cholera that came to my notice numbered 1,474, of which 1,027 terminated fatally; the mortality, therefore, was equal to 1·27 per 1,000 of population. Of these 1,474 persons 298 were born in Bombay, and 1,176 were born outside of Bombay. Of the cases

born in Bombay 188 died, and of the cases born outside of Bombay 839 died. 1,176 of those attacked are reported to have drunk Vehar and Tulsi waters, 828 dying; 198 are said to have drunk well-water, of which 142 died. In 100 cases we were unable to ascertain whether Vehar, Tulsi, or well-water was consumed; 57 of these cases proved fatal.

The greatest mortality from cholera was registered amongst Hindus, Hindu Low-Castes and Native Christians. The mortality from cholera amongst Europeans was 1·05 per 1,000 of population.

Examining the distribution of mortality from cholera over the city by districts, we observe that the highest mortalities were registered in Sewri, Mahim, Mazagon, Parel, and Warli. The high death-rate from cholera in Mazagon is not to be wondered at.

The pipe water-supply is insufficient and subject to interruptions, while the wells are liable to be constantly contaminated by percolation from adjoining cesspools, of which there are 174 in this small section, the contents of which saturate the ground, giving rise to that semi-fated humidity of soil which combined with impure water is so almost universally associated with cholera. Parel enjoys no advantages in regard to these particulars, and in certain portions of Mahim the water-supply during the recent epidemic was so notoriously bad that I had the wells shut up, and water was sent round in carts, which was followed by the most beneficial results. In Warli also the principal ostensible factors in the production of this disease were humidity of soil and an absence of a pure water-supply; so frequently, indeed almost constantly, are those two factors associated with outbreaks of cholera, that it is impossible to avoid arriving at the conclusion that they are the two principal causes or means of conveying the disease.

Fevers.

The number of deaths from fever was more than the number registered in 1882 by 456, and below the average of the previous five years by 1,656. Of the deaths from fevers, 1,439 were referred to remittent fever, being 251 more than in 1882, and 2,207 less than the quinquennial mean; to simple continued fever, 1,169 deaths were referred, being 242 more than 1882; and to ague 275, being 41 less than in 1882; to enteric fever 20 deaths were referred, being 2 less than in 1882.

The highest mortality from fever was registered in Parel, Kamathipura, Sewri, Warli, Mahim.

As in the year preceding, the Hindu Low-Castes suffered more from fevers than any other class, and the mortality was higher than in 1882, being 93 per 1,000. Contrasted with 1882, there was a diminution in the mortality from fevers amongst Europeans.

Other diseases.

Deaths referred to phthisis numbered 3,144, being 415 more than in 1882. The highest mortality occurred in Nal Bazar (Khara Talao), 2nd Nagpada, Chuckla, and Bhuleshwar, than in 1881 and 1882.

The number of deaths from phthisis was not greater than might be expected, considering the badly ventilated and fearfully overcrowded buildings in which a large number of the inhabitants of Bombay live. Much has been done by this department to improve the ventilation of dwelling-houses, but much still remains to be done. Until such time, however, as the Municipal Act is amended, and the by-laws passed, the municipality will remain in a measure paralysed in their efforts to improve the condition of dwelling-houses. It will hardly be credited, but the municipality have no power to compel an owner to improve the ventilation of his house, unless the required alterations can be carried out within twenty-four hours.

From diseases of the respiratory system 3,394 deaths were registered, 8 less than in 1882, but 673 more than the average; 1,828 were referred to bronchitis, 223 less than in the preceding year; 1,159 to pneumonia, 173 more than in 1882.

To diseases of the digestive system 2,371 deaths were referred, being 226 more than in the preceding year, but 466 less than the mean of the previous five years; 1,169—being 67 more than the past year and 56 more than the average of the previous five years—were referred to diarrhœa; and 646—being 121 more than in 1882 and 446 less than the mean of the previous five years—to dysentery; to all other diseases of the digestive system 565 deaths were ascribed, being 28 more than the past year, and 76 less than the mean of the previous five years.

From diseases of the nervous system 2,849 deaths were registered being 292 more than the average of the previous five years.

Births.

During the year 15,182 living births, and 1,449 still-born births, were registered; of the children born living 7,902 were males and 7,280 females; the proportion of male to female births was 108 to 100; the birth-rate was equal to 18·79 per 1,000. The highest birth-rate was registered among Eurasians, 67 per 1,000.

APPENDIX.

No. I.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER with the GOVERNMENT of INDIA for 1883.

1. In dealing with this report, we shall follow the usual order, beginning with the sanitary history of British troops during 1883, which, for the sake of comparison with the history of preceding years, we have placed in the following abstract table, copied from Dr. Cuningham's Report:—

Years.	Strength.	Ratios per 1,000 Strength.				
		Admissions.	Daily Sick.	Deaths.	Invaliding.	Total Loss.
1870–79	573,446	1,475	60	19·34	45	62
1878	56,475	1,651	68	21·66	45	66
1879*	49,582	1,937	78	24·28	49½	73½
1880*	51,726	1,789	74	24·65	26½	51½
1881‡	52,728	2,095	79	16·86	38	55
1882	57,269	2,445	65	22·07	33½	45
1883	55,525	1,336	63	10·88	33	44

* Excluding troops serving in Afghanistan. † Including troops serving in Afghanistan.
‡ Calculated on the strength obtained from the annual returns.

This table shows that the year 1883 yielded the lowest death-rate for the Indian European Army of any year on record, and that there was a remarkable diminution in all the causes of inefficiency.

2. We shall next examine the facts more in detail, beginning with the ratios for each Presidency which were as follow for 1883:—

Armies.	Strength.	Ratio per 1,000 Strength.				
		Admissions.	Daily Sick.	Deaths.	Invaliding.	Total Loss.
Bengal	34,079	1,463	56	11·51	31	42
Madras	20,496	1,013	39	10·19	33	43
Bombay	10,948	1,249	57	10·50	38	48

The death-rates in the Madras and Bombay Armies have been nearly the same for the last year or two; but perhaps the most satisfactory data are those supplied by the Bengal Army, which shows a continuous reduction in the elements of inefficiency, except during the war years, which yielded an increase, as usually happens.

3. The next abstract gives the facts for the Bengal Army alone:—

Years.	Ratio per 1,000 Strength.				
	Admissions.	Daily Sick.	Deaths.	Invaliding.	Total Loss.
1870–79	1,522	61	21·00	41	62
1878	1,675	68	21·63	40	62
1879*	2,108	82	29·37	47½	77½
1880*	1,843	75	27·75	22½	50½
1881*	1,739	72	17·05	37½	54½
1882	1,579	69	18·17	25	43
1883	1,463	66	11·21	31	42

* Excluding troops in Afghanistan. † Including troops in Afghanistan.

The ratios in this Bengal table show clearly the influence of the Afghan war years. We have the declining rates before the war, then the increase consequent on the war, and finally the progressive reduction thereafter.

4. The data for the Madras Army are as follow. They bear marks, not of the Afghan war years, but of the epidemics which accompanied the famine:—

Years.	Ratio per 1,000 Strength.				
	Admissions.	Daily Sick.	Deaths.	Invaliding.	Total Loss.
1870-79	1,264	60	27·69	49	67
1878	1,392	66	21·82	48	70
1879	1,428	68	16·66	45	62
1880	1,368	64	10·18	20	30
1881	1,160	60	10·97	28	39
1882	1,058	57	10·25	24	34
1883	1,013	59	10·19	33	43

The reductions in this table are not so satisfactory, on account of the increase of invaliding in 1883; but the improvements in health and efficiency have been more steady, and the death-rate has remained low for a succession of years.

5. The next abstract gives the data for the Bombay Army, from which troops were detached for service in Afghanistan, and the influence of this occurrence is shown in the table:—

Years.	Ratio per 1,000 Strength.				
	Admissions.	Daily Sick.	Deaths.	Invaliding.	Total Loss.
1870-79	1,533	57	15·27	43	58
1878	1,848	67	20·46	58	78
1879	2,173	78	15·78	60	76
1880	2,150	76	30·90	49	80
1881*	1,784	72	13·44	53†	67†
1882	1,405	61	10·37	36	46
1883	1,249	57	10·50	38	48

* Excluding troops in Afghanistan. † Including troops in Afghanistan.

Estimated by the standard of attainable mortality under the operation and extension of sanitary improvement laid down by the Royal Commission for times of peace, these statistics for the armies of the Presidencies are satisfactory. But they also show to what an extent the general health of the army is under the influence of causes of sickness and mortality incident to field service, and quite apart from field casualties, and they clearly point out how great would be the advantage not only for efficiency in the field, but for the general standard of health, if disease causes on service were as far as practicable prevented or removed, as is being done at stations.

6. The statistical abstracts for Madras and Bombay show, with sufficient clearness, the course of sanitary improvement; but as the greater part of the army is stationed in the diverse regions which make up the Presidency of Bengal, we shall give the death-rates for the different army groups, to show where the reductions have taken place:—

Years.	Death-rates per 1,000 Strength.					
	Bengal Proper.	Gangetic Provinces and Oudh.	Meerut and Rohilcund.	Agra and Central India.	Punjab.	Hill Stations.
1860-69	29·57	28·59	26·61	38·48	25·24	14·78
1870-79	14·43	20·06	18·31	18·41	20·71	12·23
1880	16·03	29·32	22·98	15·07	36·41	20·75
1881	12·02	15·94	27·81	10·11	23·44	9·97
1882	11·19	22·61	8·86	10·51	18·12	8·65
1883	9·10	17·04	10·56	14·27	9·47	6·53

This abstract shows that sanitary improvement in all the groups of the Bengal Army, although subject to occasional interruption, has been continuous, and that to all appearance the very high rates of the earlier years have finally passed away.

7. In previous memoranda, we have stated the causes of the reduced death-rates, and we shall continue the data down to 1883, and in doing so, we shall restrict the comparisons to the more fatal

diseases of the epidemic group, namely, cholera and fever, as having the most important influence on the total mortality of the years :—

Years.	Ratio of Deaths per 1,000.								
	Bengal.			Madras.			Bombay.		
	Cholera.	Fevers.	All Causes.	Cholera.	Fevers.	All Causes.	Cholera.	Fevers.	All Causes.
1866–69	2·24	—	—	—	—	—	—	—	—
1870–79	4·16†	4·92	21·0	1·68	2·04	12·69	1·33	2·39	15·27
1880	4·84*	5·73	27·73	·16	1·75	10·18	—	3·99	30·90
1881*	3·22	3·45	17·05	1·73	·27	10·97	·80	3·74	15·44
1882	1·28	3·67	13·17	·82	2·36	10·25	·63	2·72	10·37
1883	·94	2·98	11·21	·95	3·14	10·19	·82	2·29	10·50

* Excluding troops in Afghanistan. † In this ratio are included 365 cholera deaths in Afghanistan.
The fever mortality for 1879 includes Afghanistan deaths, and from 1880–81 these deaths are excluded.

The first result of this table is, that it shows a large reduction of the total mortality, apart from the notable decline in cholera mortality. Fever has declined in Bengal, but it is a more persistent death cause in Madras and Bombay, more particularly at Madras stations. The facts taken as a whole appear to justify an expression of opinion, that improved health is due to sanitary work at the stations, and to better habits among the men, and improved administration generally.

8. We shall next discuss the disease history of 1883.

The average strength of the European Army was, as has been already stated, 55,525. The total admissions from all causes were 74,163, equal to an admission-rate of 1,335·7 per 1,000 strength. Of the admissions, 23,130 were due to fevers. The fever-rate per 1,000 strength was 416·5, and this disease group gave rise to 31 per cent. of the total admissions of the year. The diseases next in importance after fevers were those of the venereal group, which yielded 15,006 admissions, or 270·3 per 1,000 strength. Wounds and accidents followed next in order, with, 6,247 admissions, equal to a ratio of 112·5 per 1,000. Diseases of the respiratory organs, including 347 cases of phthisis pulmonalis, gave rise to 4,562 admissions, or 82·2 per 1,000. There were 290 cases of alcoholism and delirium tremens, 1,495 of dysentery, 2,573 of diarrhœa, and 1,602 of hepatitis. Rheumatism yielded 2,742 admissions. The disease usually considered the most formidable of epidemics, cholera, had only 82 cases admitted to hospital.

These data will afford sufficient indication of the main causes of inefficiency during the year for the Indian European Army as a whole.

9. The corresponding death statistics from the chief causes of mortality, were as follow: but in dealing with the data we shall give the totals only for the army as a whole, and then the deaths per 1,000 for each of the three armies :—

Causes of Death.	Army of India.		Death-rates per 1,000 Strength.		
	Total Deaths.	Deaths per 1,000.	Bengal.	Madras.	Bombay.

Out of the 604 deaths in this table, 21 were suicides, so that the total deaths from disease were 583, or 10½ per 1,000. Cholera occupied only a very subordinate position among the year's death causes, and the mortality from it was pretty nearly equalised all over the armies. The chief death cause was enteric fever, which was most fatal at Madras stations. As usually happens, Madras yielded the highest death-rate from hepatitis; and Bombay returned the highest rates from respiratory diseases and phthisis combined.

10. As we have discussed the death cause at stations of Madras and Bombay troops on other papers, we shall confine our remarks on the data furnished by this table chiefly to those relating to Bengal stations, and to the army as a whole, beginning with cholera.

During 1883, cholera gave rise to a death-rate of ·54 per 1,000 in the stations of Bengal proper, to 3·92 per 1,000 in those of the Gangetic provinces, to 1·25 per 1,000 in Agra and Central India, while Meerut and Rohilcund, Punjab, and the hill stations escaped the disease. The death-rate of ·54 per 1,000 in Bengal proper represents only a single death in Fort William, so that virtually the cholera of 1883 was confined to two military groups, the Gangetic provinces and Agra and Central India. In the former group, Dinapore yielded 7 deaths, Benares 1, Chunar 4, Lucknow 2, Cawnpore 1 death, and Allahabad 11 deaths; in all, 26 deaths for this group. In Agra and Central India cholera deaths, 5 in number, were returned from Gwalior fortress, so that only 8 stations out of 56 in Bengal Presidency were attacked. In Madras and Bombay, only 7 stations out of 39 suffered, and yielded 17 deaths. These did not include deaths on the march. The whole cholera mortality of the year thus took place at 15 stations out of 95, and more than half of the whole years mortality took place at six stations in the Gangetic provinces and Oudh, where 18,160 cholera deaths were registered among the civil population. In Allahabad district itself there were 598 cholera deaths registered, so that the 11 deaths among the troops were part of the epidemic.

11. *Enteric fever.*—We have already seen that this was the most fatal disease of the year. It gave rise to 429 admissions in the whole army, and of these 133, or 31 per cent. proved fatal. In the absence of this fever the year's death-rate would have been 3·43 per 1,000. Of these 133 deaths 86 took place at Bengal stations, and, unlike what took place with cholera, all the military groups, including hill stations and depôts, yielded deaths. The disease showed itself at 31 stations in Bengal Presidency, at 13 stations in Madras and Bombay. At the Punjab stations which escaped cholera there were 25 deaths from this fever, and in the Gangetic provinces, the stations which yielded 26 deaths from cholera, returned 21 deaths from enteric fever. The total deaths from all fevers in the Indian Army amounted to 159, or 2·86 per 1,000 strength, and of these deaths 133, or 83 per cent., were attributed to this fever. It may now be considered as a settled point in its history that, however much its diagnosis may be obscured by paroxysmal symptoms, it is in India a distinct fever. In the present Report it is shown that, for every case of enteric fever admitted in Bengal, 60 are admitted for other fevers, while in Madras 15 fever cases are admitted, and in Bombay 77. As regards the deaths, the statistics show that, out of a total fever death-rate of 2·86 per 1,000 for the whole army, all except 0·46 per 1,000, were due to enteric fever. We have so frequently discussed the numerous questions connected with this fever that it appears to be unnecessary to do more than to give a very brief abstract of the year's facts, as these are stated in the Report under review for the purpose of keeping up the continuity of its history.

12. The experience of medical officers during 1883 confirms that of previous years as to difficulties in diagnosis of this fever. There is absence of uniformity in the symptoms, and want of some of them in certain cases. The duration of cases is very various. At Umballa the average duration of favourable cases was 43 days. But one case ended fatally at the same station on the second day. At Morar a case ended fatally 36 hours after admission. A fatal case is mentioned in which the Peyerian patches were intact. The eruption is stated to be more frequently absent than present. Diarrhœa is said to be invariably absent until ulceration has set in. Pulmonary congestion "sets in early." A case is mentioned in which a careful and competent officer diagnosed a case as pneumonia which proved to be a virulent case of enteric fever, ending fatally in seven days. The previous appearance of paroxysmal symptoms, and of those of continued fever, often complicates the diagnosis, and hence the ratios of deaths to attacks vary greatly, and sometimes the term "enteric fever" is made to include all severe cases of fever. All these are well known difficulties in dealing with this fever in India, and they all enter as important elements into the question of diagnosis, but there can now be no doubt that enteric fever must henceforth be admitted as the most common of Indian fatal fevers.

13. Questions connected with liability to this fever presented the usual aspect. In 1883 the per-centage of men in the Indian Army under 25 was 41, and their enteric fever liability was 66·36 per cent. Between 25 and 29 years of age the per-centage of strength was 35, and the per-centage of liability was 22·94. Of men of 30 years of age and upwards the per-centage of strength was 24, and the per-centage of liability was 10·70, but no fatal case appears to have occurred after the age of 34.

As regards the influence of length of service in India on the mortality of enteric fever the facts in 1883 were as follows. The per-centage of men who had served for two years and under was 32·3, and their per-centage of liability was 70·32. Of men with five years' service and under the per-centage was 74·2, and the per-centage of liability between the third and sixth years was 21·89. Of men with seven years' service and under the per-centage was 85·5 But no separate liability ratio is given. It appears that in 1883 only 14·5 per cent. of the troops had served longer than seven years, and the per-centage of liability among this group had been 7·7 It follows from these data that we now know that enteric fever is the fatal fever of India, and that it is most fatal at ages under 25, and in the first two years of Indian service.

14. If there are difficulties in the diagnosis of enteric fever there are also difficulties in arriving at its local etiology. So far as concerns the subject, the soldier, the data accumulated during past years all point in the same direction. Whatever may be the local etiology of enteric fever, the relation of this fever to age is now established, and of course the sanitary conclusion is to endeavour to send older soldiers to India.

As regards the local etiology, Dr. Cuningham states that "no positive results of any value have "been arrived at." But there are nevertheless certain facts stated by medical officers which are very much in accordance with facts connected with enteric fever in Europe.

For example, one medical officer states that foul tank water used for wetting tatties frequently "emitted a most offensive and putrid odour." This case may be referred to, because it is by no means unlikely that this method of cooling air by passing it over wetted decomposable material is an unsafe practice in a hot climate. In another case dirt from cows' udders getting into the milk is stated as a probable cause. Bad water and the drying up in summer of foul tank surface is also suggested.

The facts connected with local outbreaks appear to point to general causes. Thus, at Lucknow, there was an outbreak, and 44 cases took place in regard to which the medical officer says that, "even in the barracks occupied by the regiment which supplied most of the cases, there was no "marked prevalence in any building or locality."

A similar remark is made about the cases at Jubbulpore and Cherat. No transference of the disease by infection was observed.

It would have helped us to a solution of the etiological question if we had been informed of the steps which had been taken to improve the drainage, water-supply, and conservancy of Lucknow where the 44 cases of enteric fever took place, for it is certain that in older reports there were causes described sufficient to account for any number of enteric fever cases. There is nothing in the present Report to lessen the importance we have all along assigned to local defects, such as those stated above, in the chain of events. The practical result is that, without losing time in trying to assign its special importance to every local cause, which moreover we have no means of doing, we are fully justified in advising that these enteric fever stations should be continuously improved, especially by drainage of the subsoil, where in all probability the real evil exists.

15. Enteric fever is what may be called a constant quantity in Indian Army death-rates, as the following abstract shows. It does not come and go like cholera. It is liable to temporary periodic increase and decrease, but it is always there doing doing its deadly work.

Annual Admissions and Deaths per 1,000 from Enteric Fever.

Years.	Bengal.		Madras.		Bombay.

‡ Statistics incomplete at the Commissariat's Office.

This table shows a remarkable reduction in the prevalence of dysentery all over India. It also shows a progressive diminution of its fatality. The disease and its treatment are better understood, and part of the lower death-rate is probably due to this cause. But the actual amount of the disease has undergone a great diminution, as sanitary work has made progress at the stations, especially in water-supply. And the facts as they stand may also lead us to the conclusion that the soldiers' personal habits have been undergoing improvement. We have no means of knowing to what extent improvements in night ventilation to prevent chills may have been introduced, but as exposure at night to hurtful air currents has been assigned by competent medical officers as one cause of dysenteric attacks, and as the disease still gives rise to a notable death-rate (there were 21 deaths from it in 1883), it may not be out of place to recall attention to this detail.

17. *Diarrhœa.*—Deaths classed under this head are not among the chief death causes in the Indian Army, but it is satisfactory to know that a marked reduction has taken place in their

prevalence. During the ten years' period 1870–79, the diarrhœal death-rate was 0·12 per 1,000. In 1880 it was 1·32. In 1881 the rate was 0·32. In 1882 it had fallen to 0·07, and in 1883 to 0·04, per 1,000.

18. *Hepatitis.*—The next abstract shows that diseases of the liver have also declined in severity, except in the Madras Army, where they have been generally more prevalent than in those of the other Presidencies:—

Years.	Death-ratios per 1,000 strength.			
	Army of India.	Bengal.	Madras.	Bombay.
1860–69	—	3·34	—	—
1870–79*	2·19	2·04	3·16	1·71
1880	1·34	1·36†	1·26	1·31
1881†	1·60*	1·64	1·54	1·52
1882	1·40	1·48	1·72	·81
1883	1·13	1·06	1·72	·82

* Including troops on active service, and on the march. † Excluding troops in Afghanistan.

19. *Sunstroke* and *apoplexy*, the deaths from which are to a large extent climatic, cannot be expected to show steady reduction in amount even when the general health of the army may be improving. For the whole Indian Army these affections yielded an average death-rate for the ten years' period 1870–79 of 1·52 per 1,000. In 1880 the rate had increased to 2·69 per 1,000, chiefly in Bengal. In 1881 the rate had again fallen to 1·43 per 1,000 and to 0·85 per 1,000 in 1882, to be followed by a rise to 1·19 per 1,000 in 1883. From what we know of the soldiers' habits, it may be safely predicted that mortality under this head ought not to be altogether attributed to the sun. Some of it, at least, is due to intemperate habits, especially to the use of spiritnous liquors.

20. *Respiratory diseases.*—There has been a marked reduction in deaths under this head in all the armies, subject, however, to occasional augmentations. The whole army yielded a death-rate from chest affections of 0·97 per 1,000 during the years 1870–79. In 1880 the rate was 2·93 per 1,000, which has declined during the three subsequent years to 1·76, 1·75, and 0·67 per 1,000.

21. *Venereal diseases.*—The present Report contains full details of the year's experience of these diseases in all the armies. It is unnecessary to discuss the subject, as all the past experience shows that none of the methods hitherto adopted for dealing with them appear to have made any material impression on their amount. The authorities in India are fully alive to the questions which have arisen in regard to them, and all we think it necessary to do is to state the facts, which show exactly the point at which we have arrived in our attempts at prevention by lock hospitals, registration, and police measures. They have been as follows:—

Armies.	Venereal Admissions per 1,000.					
	1860–69.	1870–79.	1880.	1881.	1882.	1883.
Bengal	265	209	276	276	272	281
Madras	—	198	275	258	288	289
Bombay	—	191	269	261	224	238
India	—	203	250	240	265	270

These are the main facts, but, of course, the exact amount of injury to efficiency which venereal diseases give rise to depends in its degree on the nature and severity of the cases. During 14 years Dr. Cuningham gives the admissions at unprotected stations as 227 per 1,000, and for protected stations at 223·1 per 1,000. The only hopeful matter about the case is that the improvement was due entirely to Bombay stations, at which the protected stations yielded an admission-rate of 200·7 and the unprotected stations of 240·7 per 1,000 during these years. Cannot the Bombay methods be tried elsewhere? Some saving might possibly be effected, but, with the experience shown in the abstract, there is scarcely much to be hoped from them.

22. *Invaliding.*—Any attempt at estimating advances in army health must necessarily be unreliable, unless the extent to which the removal from India of broken constitutions has influenced the local death-rates is taken into account. The deaths from all causes in 1883 numbered 604, and 702 men were invalided for discharge from the service. If these men had been retained in India, it is very probable that some of them would have been added to the mortality loss of the year. But besides these invalids, who must be considered as absolute loss to the army, there were 1,073 men sent away for change, among whom, no doubt, there were weakly men near the end of their term of service. It usually happens that a proportion of this class is restored to health on the voyage, and many rejoin their depôts on arrival at home.

The annual number of invalids of both classes is contingent on the general health standard of the Indian Army at the time, and this is influenced not only by locality and by conditions of Indian service, but also by the constitution and periods of service of regiments. And hence it is not easy to state what amount of influence on the death rates in India is really exerted by invaliding, especially as in times past there have been differences in practice in this matter in the Presidencies.

In 1883 the proportion of men invalided for discharge was 39 per cent. of the total invalids, against 35 per cent. in 1881, and 37 per cent. in 1882 for the whole Indian European Army. But the proportions varied between 21 per cent. in Bombay and 45 per cent. in Bengal. Yet even in this case it cannot be predicated that Bengal kept down its death-rate by its high proportion of invalids for discharge, unless the actual rate per 1,000 of total invalids had also risen.

23. Perhaps, on the whole, the smallest extent of error in forming an estimate of the actual sanitary progress of the Indian Armies will be simply to quote Dr. Cuningham's table, in which the chief elements of inefficiency in each army are placed in parallel columns as follows :—

Years.	Ratio per 1,000 Strength.								
	Bengal.			Madras.			Bombay.		
	Admissions.	Deaths.	Invalids.	Admissions.	Deaths.	Invalids.	Admissions.	Deaths.	Invalids.
1870	1,732	22·68	59·42	1,456	20·94	78·93	2,563	26·27	29·17
1871	1,508	17·83	44·54	1,193	20·10	45·32	1,518	14·02	30·54
1872	1,514	27·45	43·18	1,357	18·98	35·27	1,588	18·86	40·62
1873	1,350	15·40	37·75	1,271	18·29	32·57	1,816	11·72	41·66

* Excluding troops in Afghanistan. † Including troops in Afghanistan.

This table contains the data on which our view of the health of each Presidency Army and its causes must be based. It shows the variations in individual years common to all vital statistics, especially to those of an epidemic country. But the data taken as a whole show :—

(1.) That in Bengal Presidency, where above half the whole European Army is in cantonments (34,079 in 1883), there has been a reduction in the admission-rates, interrupted in individual years, but the general tendency has been downwards; that there has been a large reduction in the death-rates, increased, however, for the time by men who had returned to Indian stations from Afghanistan, and that these reductions have not been attended by increase of invaliding, but, on the contrary, by reduction in this element.

(2.) That Madras Army shows an irregular reduction in the admission-rate, and an almost continuous reduction in the death-rate, with a large corresponding diminution of invaliding.

(3.) That admissions have undergone irregular reductions in the Bombay Army, part of which was engaged in Afghanistan, and suffered in consequence on returning home. That, with occasional interruptions due to this cause and to epidemics, the death-rate has declined and continues low, but that, although the amount of invaliding in the Bombay Army has been large, there is no evidence in the table that it has been used to keep down death-rates, or has had any such effect. Indeed, it follows as a matter of course, that, if the medical administration in this matter be uniform, and if the health of the army is undergoing improvement, there ought, with a diminishing death-rate, to be a diminishing admission-rate, at least from local disease causes, and also a reduction in the invaliding, and this is the teaching of this table. There is no evading the result of the facts as a whole, that the health of the European Army in India has undergone remarkable improvement since the Royal Commission of 1859 began its inquiry, and there is every reason to accept its conclusion, that a death-rate of 10 per 1,000 ought to be the death-rate of the Indian Army in time of peace.

24. The experience of newly arrived regiments in 1883 was as follows. The strength was 1,453. The admission-rate was 1,737·8 per 1,000. The daily sick-rate was 82·6 and the death-rate 19·96 per 1,000, or not far from double the rate for the whole army. Of this high death-rate 8·95 was due to one disease, enteric fever, which caused the entire fever death-rate. As already stated, the enteric fever death-rate for the whole army was 2·40 per 1,000. It is clear that large arrivals of men new to Indian service must exercise a notable influence on the death-rates, and hence, when there are few new regiments sent out, the general army rate will be lower than it would be otherwise.

25. *Soldiers' wives and children.*—The numbers under this head have been steadily decreasing. In 1883 there were 3,290 women and 6,015 children at the stations. The death-rate among the former was 21·28 per 1,000, of which 3·65 was due to child-birth and abortion. Deducting this from the general rate, the deaths from disease would be 17·63 per 1,000. The total death-rate among women has been declining with improved health. Children's death-rates have also notably decreased. Within the last few years they have been as high as 7½ per cent., or even higher, while in 1883 they were 46·88 per 1,000. The greater part of the mortality was due to infantile diseases.

26. *Mortality of officers.*—In 1883 there were 2,900 officers in the British Army and 3,215 in the Native Army in India. In both services combined there were 75 deaths, or a ratio of 12·2 per 1,000. In 1881 the death-rate of officers was 15·67 per 1,000, and in 1882 the death-rate was 12·16 per 1,000. Hence the death-rates have been falling throughout the whole army.

27. *Native Army of India.*—The strength of the Native Army in 1883 was 114,830, and the various inefficiency rates stood as follows:—

	Per 1,000.
Admissions to hospital	923
Daily sick	31
Deaths in hospital	11·76
Mortality, including absent deaths	14·31

The admissions and daily sick-rates were the lowest during seven years, and with the single exception of 1877, the death-rate was the lowest in the series.

The following were the inefficiency rates for the Native Armies of each Presidency:—

Armies.	Ratio per 1,000 Strength.		
	Admissions to Hospital.	Daily Sick.	Deaths, including absent Deaths.
Bengal	985	32	13·98
Madras	737	27	12·51
Bombay	994	35	14·96

The hospital death-rates were lower, of course, than those in this abstract, and were for Bengal 10·55, for Madras 10·76, and for Bombay 12·81 per 1,000.

The differences are due to the Native practice of preferring, in many cases, to return to their homes when seriously ill.

28. The Native regular Army all over India, like the European Army, shows improved and improving health, but the progress in the former army has not been so rapid as in the latter. Still the improvement in health is common to the whole military forces of India.

In the other Native Army groups the year's statistics give the following results:—

Forces.	Ratios per 1,000 Strength.			
	Admissions.	Daily Sick.	Deaths in Hospital.	All Deaths.
Central India Regiments	595	19	7·89	10·16
Punjab Frontier Field Force	1,419	45	21·46	23·35
Hyderabad Contingent	572	20	7·59	9·31

29. We shall conclude this brief sketch of the sanitary state of the European and Native Armies in India by comparing certain elements of inefficiency which the statistics present.

The total admissions among European troops amounted to 1,335·7 per 1,000, and among Native troops to 923·5 per 1,000. The excess among European troops was 412·2 per 1,000, partly accounted for by admissions for venereal diseases, which were 270·3 per 1,000; while among Native troops the corresponding admissions were 31·6 per 1,000. We can thus strike off from the 412·2 per 1,000 about 238·7 per 1,000, which leaves a balance of 173·5 from other diseases against British regiments. Fevers of all classes occasioned 387·6 per 1,000 admissions in Native regiments against 416·5 in British regiments. The excess was mostly made up of the severer fever types, but the admissions from intermittent fever, which amounted to 359·3 in British regiments, were 377·1 in Native regiments. This is what usually happens.

30. As regards the death-rates, the following facts are of interest:—

Death Causes.	Ratios per 1,000.	
	British Regiments.	Native Regiments.
Cholera	·92	1·15
Enteric fever	2·40	1·41
Intermittent	·05	
Remittent and continued	·41	
Apoplexy and delirium tremens	1·24	·21
Dysentery	·38	·46
Diarrhœa	·04	·37
Hepatitis	1·13	·18
Respiratory diseases	·67	3·91
Phthisis pulmonalis	·68	·70
Dropsy	·04	·23
Anæmia and debility	·02	·43
Scurvy	·09	·14

It will be seen that in 1883, at least, the balance of cholera mortality had been turned against the Native regiments instead of against the European troops, as was formerly the case. But it is otherwise with the fever death-rate, which was 2·86 per 1,000 in European regiments, or above double the rate, 1·41 per 1,000, among Native troops. But of the European excess all but ·46 per 1,000 was due to enteric fever. It would be quite safe to attribute the 1 per 1,000 death-rate from apoplexy, delirium tremens, &c., in the British regiments to drink. The table shows that Native troops suffer more from dysentery and diarrhœa than British troops. But the mortality from hepatitis, partly due likewise to drink, is nearly sevenfold greater among British than among Natives, phthisis pulmonalis is most fatal among Natives, but the most striking difference between the two armies lies in the nearly sixfold mortality from respiratory diseases in the Native regiments.

The death-rates from dropsy, anæmia, and scurvy are all higher in the Native regiments, in the ratio of ·8 per 1,000 to ·15 per 1,000 in the European Army.

So far as can be estimated from one year's returns, the health of the Native Army would be improved by better housing, clothing, and feeding, while the European Army would improve its health by giving up spirit drinking, and pressing forwards the sanitary improvement of stations, especially in the matter of drainage, and in the general care of the health of young soldiers, so long as the strength in India has to be kept up at young ages.

31. So far as relates to the sanitary improvement of British stations, the chief lesson taught by the year's statistics is that effort should be strenuously directed towards the drainage and general improvement of enteric fever stations. These are all known, and are duly set forth in Tables 22 and 24 of the present Report. The chief offenders are the stations in the North-West Provinces and Oudh, such as Dinapore, Fyzabad, Lucknow, and Sitapur; and Secunderabad and Kamptee in Madras. In making this recommendation we are only repeating what we have urged year after year.

32. No better guide to the disease causes at Native stations could be desired than is contained in an abstract of returns from Native stations given in the body of the Report.

With the facts stated in this document we can only express surprise that the Native Army suffers so little as it does. There are no corresponding data for the lines of British troops, but the general defects in sanitary details, apart from the special defects in Native lines, set forth in the returns are by themselves quite sufficient to point to the local fever causes which form so prominent an element in the inefficiency and mortality of British regiments at the same stations.

Jails in India.—The average population of all the jails in India during 1883 was 88,174. The following abstracts include the chief statistical data bearing on the health of prisoners during the year:—

Total admissions to hospitals	87,797 = 995·7	per 1,000 strength.
Daily sick	3,220 = 36·5	
Deaths	2,766 = 31·37	

It may be safely stated that the death-rate of 31·7 per 1,000 is not a high rate when compared with the probable death-rate of the outside population, and as will be seen from the next abstract, the rates as a whole are the lowest on record.

Years.	Strength.	Ratios per 1,000 Strength.		
		Admissions to Hospital.	Daily Sick.	Deaths.
1872-76	99,758	1,016	?	36·24
1877-81	112,670	1,189	44·9	63·01
1880	106,763	1,213	46·0	48·31
1881	100,844	1,214	45·8	44·33
1882	94,063	1,214	42·0	39·96
1883	88,174	996	36·0	31·37

* The years of greatest mortality in this abstract are those of the famine period following 1876. In those years there was a great influx of half-starved people, many of whom committed crimes for the

purpose of being fed in prison. The consequence was great overcrowding and its attendant conditions, and great mortality. When the disease and death rates are compared with the strength of each year, there is an evident relation between the two, and the conclusion from the facts would hence appear to be that, given the present extent of prison accommodation and its present sanitary arrangements, the admission and death-rates are to a certain extent dependent on the average occupation, and hence that crowding is an efficient disease and death cause in Indian jails.

This inference is, moreover, sustained by the sanitary notes contained in the reports for 254 jails, which show in many cases that overcrowding was one of the disease causes alleged by medical officers as having been more or less present during the year.

34. A further analysis of the data shows that rates were by no means uniform, but differed greatly in different jail groups, as stated in the following abstract for 1883 :—

Districts.	Ratios per 1,000 Strength.		
	Admissions to Hospital.	Daily Sick-rate.	Deaths.
Bombay Presidency	733·7	26·9	34·33
Berar	558·5	14·2	8·49
Madras Presidency	861·2	32·1	29·87
British Burma	1,158·7	38·8	28·94
Andamans	1,454·0	67·0	19·63
Assam	2,125·2	56·4	43·12
East and North Bengal	1,504·8	50·6	64·78
South West Bengal and Chota Nagpore	1,299·6	49·3	69·87
Behar	1,124·5	41·0	33·9
North-West Provinces and Oudh	408·0	16·9	10·28
Excluding Oudh	611·9	25·0	22·79
Central Provinces	219·2	35·6	70·97
Punjab	951·0	26·9	29·11

These data show how very different are the sick and death-rates in different groups of jails. It is true that the facts only apply to a single year, but they are quite sufficient to justify a recommendation that the whole subject of current comparative death rates and the causes of their differences should be inquired into. It need scarcely be stated that these local facts detract considerably from the favourable impression produced by the year's statistics when taken over the whole prison population.

Death-rates in individual jails differ just as widely or more so than they do in jail districts. There is one jail in the list, Rungpore, with 240 prisoners, which returns of death-rate of 183·33 per 1,000, in the entire absence of cholera. In another case, Julpaiguri, 118 prisoners yielded a death-rate of 162·39 from cholera and 136·76 per 1,000 from other causes, so that this jail lost 30 per cent. of its inmates during the year. Midnapore jail, out of 797 prisoners, had a death-rate of 102·89 per 1,000, of which only 1·25 was due to cholera. Among 607 inmates in Gorakpur jail the death-rate from cholera was 62·60, and from all other causes 84·02 per 1,000.

We have often adduced facts of this class. They are indeed well known, and their lesson is that the way to make the most immediate impression on these jail rates is to take such extreme cases in hand, to trace the causes wherever they may be, and to deal with them.

It is right to state that the present year's Report contains fewer of these anomalous high rates than the Reports of many previous years, and we are glad to state that Coimbatore district jail, which was a great offender in this respect, had a death-rate in 1883 of no more than 21·28 per 1,000; even lower than the Central jail, which was 28·35 per 1,000.

35. *Death Causes in Jails.* We have already seen that the average death-rate taken over the entire prison population of 88,174 was 31·37 per 1,000, representing 2,766 deaths from all causes during the year. As diagnosis in prisons is in all probability not far from the truth, it will be useful while giving the death ratios to introduce the admissions from the chief diseases as follows :—

Diseases.	Admissions to Hospitals.	Total Deaths.	Ratio per 1,000 Strength.	
			Admissions.	Deaths.
Cholera	351	201	4·0	2·28
Small-pox	105	10	1·2	·11
Fevers, enteric	15	2	·2	
„ intermittent	31,008	61	351·7	2·32
„ remittent and continued	1,516	153	18·3	
Dysentery	7,013	455	79·5	10·64
Diarrhœa	7,499	483	85·0	
Apoplexy	101	51	1·1	·58
Hepatitis	87	19	1·0	·22
Spleen diseases	591	23	6·7	·26
Respiratory diseases	4,232	467	48·0	5·30
Phthisis pulmonalis	502	196	5·7	2·22
Anæmia and debility	2,421	100	27·5	1·81
Scurvy	315	15	3·6	1·5
All causes	87,707	2,766	995·7	31·37

This table shows that about a third of the whole year's mortality was due to diarrhœa and dysentery, and not far from a fourth part arose from respiratory diseases and phthisis. Cholera was a subsidiary death cause only. Out of these 87,707 admissions which were diagnosed by professional observers, this abstract shows that 37 per cent. arose from fevers, but the actual fever mortality was only 8 per cent. of the total mortality. This patent fact helps us to estimate the value of the high fever-rates returned from among the civil population, as does also this other fact that the actual fever mortality among the prison population scattered all over India was only 2·32 per 1,000 of that population, instead of 8, 10, 15, 20, or 25 per 1,000, rates which are not unfrequently met with in district tables. The death causes which point specially to the need of remedy are those of dysentery and diarrhœa. In some of the reports these are attributed to dietetic defects, but cold and night chills may also act as causes, and way the subject should be inquired into and remedial measures applied. While making this recommendation we can at the same time fully acknowledge the generally improved sanitary state of Indian prisons as a whole shown by the statistics of 1883.

36. *General population.*—In our Memorandum of Dr. Cuningham's Report for 1882 we give the details of vital statistics for all the Governments of India, and we shall merely give the general results as affording sufficient data for the year 1883.

The population for the whole of India, including the Native States, on the census of 1881, was 253,891,821. This vast aggregate was made up of 129,941,851 males and 123,949,970 females, inhabiting 1,272,588 square miles of country in the ratio of 185 persons per square mile. The whole population was distributed among 714,707 villages, scattered over the area at the rate of 52 towns and villages to every 100 square miles of area.

The whole of this population is not, however, under registration of births and deaths. In 1883 deaths were returned from among a population of 197,614,787, living within 4,676 registration circles. But in Bengal, with its population of 66,168,884, births are registered only in 46 municipalities and towns, having a population of 1,685,159, under the impression that a more reliable birth-rate could thus be obtained, and so estimated for the whole province, than could be arrived at by attempting birth registration in each of the 648 circles of the province.

Independently of local inaccuracy of record and diagnosis the method of arriving at the facts is by no means perfect, but it may be stated with truth that efforts are being persistently made to improve the whole registration.

37. In our memoranda on the reports of local Sanitary Commissioners we have discussed this subject of registration as it relates to different Governments, and we shall therefore give the general results briefly as part of the year's sanitary history.

The following abstract gives the birth and death ratios for each province in 1883:—

Province.	Ratios per 1,000.	
	Births.	Deaths.
Bengal	22·03*	18·82
North-West Provinces and Oudh	40·84	27·57
Punjab	39·00	25·25
Central Provinces	40·59	34·56
Berar	40·30	51·30
British Burma	22·92	14·67
Assam	23·91	27·14
Madras	27·70	19·00
Bombay	30·50	25·53
Mysore	24·10	15·11
Coorg	13·48	21·75

* Mean of 46 municipalities.

These ratios represent only the present results attained. The least satisfactory are those for Bengal. In some the registration itself is in defect, in others the population element used in calculating the ratios is under-estimated or over-estimated. The best results appear to be those reported from the North-West Provinces and the Punjab, but taken as a whole they can scarcely be admitted as setting forth the relative sanitary state of the provinces.

38. We shall next give a brief account of the death causes in 1883, arranged under the customary heads. The actual registered deaths were as follows, for the total registering population of 197,614,787:—

Diseases.	Total registered Deaths.	Ratio per 1,000 of Population.
Cholera	244,376	1·23
Small-pox	232,363	1·12
Fevers	2,879,659	14·63
Bowel complaints	261,623	1·33
Injuries	76,059	0·39
All other causes	889,243	4·50
All causes	4,583,323	23·20

It will be observed that, with the exception of small-pox, cholera was the least fatal of the year's epidemics. In our memoranda on the provincial reports we have given the histories of local outbreaks, and we must refer to these for details, but it may be of interest to inquire what has been the history of Indian cholera for a series of years, so far as this can be done from available statistical data. Unfortunately the data are not recorded uniformly, and the registration has been improving to such an extent that if the actual annual deaths had remained the same year after year the improved registration would show very considerable increase of cholera mortality.

39. The following figures for the last 10 years, 1874-83, must therefore be accepted as showing approximately how many cholera deaths were registered. This is reliable, but whether the registered deaths afford an index to the relative annual mortality is matter of estimate:—

Years.	Total Registered Cholera Deaths.							
	Bengal.	Assam.	North-West Provinces and Oudh.	Punjab.	Central Provinces.	Berar.	Madras.	Bombay.
1874 -	56,876	16,478	6,464	78	14	2	333	32
1875 -	109,998	6,616	64,427	6,246	14,648	22,465	94,547	47,573
1876 -	196,590	8,615	48,311	5,736	20,124	2,683	148,189	32,117
1877 -	155,805	11,377	31,770	29	3,418	842	357,430	57,228
1878 -	96,192	6,732	22,221	215	40,985	34,306	47,167	46,743
1879 -	136,363	17,415	35,892	26,135	27,575	223	13,296	6,937
1880 -	39,648	2,803	71,546	274	380	1	613	684
1881 -	79,180	5,010	25,865	5,207	9,449	3,404	9,446	16,694
1882 -	182,352	21,055	89,371	39	11,922	3,573	23,604	7,904
1883 -	90,439	14,908	18,160	190	16,235	27,897	36,284	37,954

On casting the eye down these columns it is impossible not to recognize how extremely variable and subject to sudden outbursts is this great epidemic disease all over India. It is apparently subject to no law of succession. One year's experience affords no guide either to the epidemic history of past years or to the probable history of years to come. At first sight certain of the columns appear to show diminishing mortality, but the very next year effaces any such impression, and leaves us with an insoluble problem. The Madras experience is no exception to this rule, although there has been a great reduction in the mortality since 1877, because this year and the year which preceded it were the years of famine, which were marked by one of the greatest epidemics on record. So far as we know such intercalated events might appear at any time, and it is to be regretted that there has been no advance in effective sanitary work among the towns and villages of the civil population, except perhaps in the case of the Punjab, to exert any marked protective power over the population.

40. Were it not that we have other experience in India than that furnished by the civil population, our hope of reducing cholera mortality by removing its local causes would be very small. But such experience as we have throws a totally different light on the figures of the preceding table, and converts them into indices of great local sanitary negligence. For example, local fairs and pilgrimages, which used formerly to be the real foci of local epidemics, have ceased to be so wherever cleanliness has been enforced, pure water provided, and overcrowding prevented. This rule holds universally, subject, however, to a very instructive exception, and this is, that the absolute immunity of the people at these fairs depends, to a certain extent, on the epidemic intensity in the district where the fair happens to be held. If the district mortality be not excessive the fair people will escape, but, if the district mortality be high, some of the fair people will suffer, but never to the ratio of the local population. That is on the supposition that the usual precautions are adopted.

Next let us take the jail experience, which is thus stated by Dr. Cuningham in his book on cholera:—"The great fact stands out that the annual average death-rate from cholera among "prisoners during the period 1859 to 1867 was 10·77 per 1,000; in the next period, 1868 to 1876, "it was 3·28 per 1,000, and in the third period, 1877 to 1883, it was 3·61 per 1,000," but this latter period includes the famine. Of course the reduction in jail cholera mortality to about a third is in one sense satisfactory, and has corresponded with the advance in sanitary improvement in prisons, and, so far, the illustration is a good one; but why, we feel inclined to ask, is there still a third of the old rate remaining? and why should this third be twice the loss from cholera among Native troops? If we take 1883 for both groups, we find the Native troops yielding a cholera death-rate of 1·15 per 1,000, and prisoners a rate of 2·28 per 1,000.

41. Experience yielded by European troops is equally instructive as to the protective value of sanitary measures during times of cholera. We have already shown what this has been, but we may reproduce the table from Dr. Cuningham's book on cholera, where it stands as follows:—

Presidency.	Annual average Death-rate from Cholera.		
	1860 to 1869.	1870 to 1879.	1880 to 1883.
Bengal - - -	9·24	4·18	2·49
Madras - - -	2·56	1·68	0·90
Bombay - - -	4·80	1·53	0·45

It ought, at the same time, to be stated that the cholera death-rate for the whole European Indian Army in 1883 was ·92 per 1,000, and for Native troops 1·15 per 1,000, as we have stated above. Let these ratios be compared with the figures for the civil populations in the previous table, which yielded for all India, including the population of large exempted areas, a rate of 1·23 per 1,000, and surely no further argument will be needed to enforce the necessity for pressing forward the sanitary improvement of towns and villages. But even in this aspect of the case we have experience to guide us. Take, for instance, the case of Bombay city, where the statistics of 17 years before the initiation of sanitary works yielded an aggregate of 37,454 deaths from cholera, and the subsequent 17 years of slowly advancing sanitary work, and increasing population, an aggregate of 12,026 cholera deaths. If similar work had been done for the Presidency the cholera death-rate ought to be a third of what it is.

But perhaps the most striking experience is that of Calcutta, because it shows the effect of cholera epidemics on two groups of population adjoining each other—the *municipal city*, within which drainage and water-supply have been in use for a number of years, and the *suburbs*, which lie outside the municipal works. The following has been the cholera mortality in these two groups for a period of five years:—

Years.	Cholera Deaths per 1,000 of Population.	
	Calcutta.	Suburbs.
1878	3·0	9·3
1879	2·7	7·4
1880	1·8	3·8
1881	3·9	7·2
1882	5·1	9·3

These figures teach their own lesson in a very practical way, although we are by no means prepared to adopt the Calcutta ratios as showing what can be done in mitigating or preventing the local causes of cholera.

42. Some account of these local causes, as they exist in different provinces, are given in the present and preceding memoranda. Our object is not to reproduce the facts, but to show that, if the knowledge and experience we already possess is turned to proper account by local authorities all over India, the cholera statistics will very speedily testify to the results to public health.

43. In previous memoranda we have given a summary of experience in cholera hospitals on the liability of attendants on cholera cases to attacks of the disease, and the following results are abstracted from tables in the present Report giving the facts for 1883. Cases of cholera, 697 in number, were received for treatment into 91 hospitals of British and Native troops and jails. Into 75 of these hospitals 303 cases of cholera were received, and were attended by 852 attendants, none of whom were attacked by cholera. Into 16 hospitals there were received 394 cases of cholera, attended on by 557 attendants, of whom 31 were attacked. No account is given of the nature of cases returned as cholera among attendants, or of the number of deaths, except the apparently incidental information in a foot note that in one hospital three sweepers had had "choleraic diarrhœa." Of 31 attacked attendants 12 were on service at one station, Kamptee, in the Central Provinces, which happened to be situated in a district where cholera prevailed with great intensity, besides being itself peculiarly liable to epidemic diseases. In 1883 there were 13 cases of cholera among British troops at Kamptee, and 185 cases among Native troops and followers, apparently, at this station. Of course, even during a great epidemic, such an occurrence is sufficient to show that there is something radically wrong at this place, and we would strongly advise that the whole subject should be inquired into, and protective steps taken for the future. The experience moreover, appears to show that local epidemic intensity renders hospital attendants more liable to attacks, as it also does other people.

44. The state of the locality itself has of course an important relation to liability to cholera during epidemic seasons, a fact which was well illustrated during this Kamptee outbreak. Two of the Native regiments which suffered had in all 192 cases of cholera, only five of which, however, took place after removal to camp.

Similar experience was obtained with British troops at Allahabad. When cholera appeared among them the men were divided into twelve parties and sent into camp. In ten of the parties the disease was checked by one removal, and in the other two by a second removal.

An incident, bearing directly on the reasons of this local liability to cholera, is mentioned by the Medical Officer of Jalpaiguri jail as follows:—"During levelling of the ground inside the jail, "peculiar stinking emanations used to appear from the dug up loose earth. It was a strange "coincidence that whenever the levelling operation was being carried on, fresh occurrence of cholera "used to take place." In this instance there could have been no subsoil drainage, as it is stated that there were dirty pools about.

In Buxar jail night-soil was buried within the jail precincts, and cholera cases were most numerous near the pits.

Similar general conditions, leading to impure emanations in close weather, as well as to foul well water, are the common localizing causes of cholera among the civil population, and there is besides

all the beneficial experience of removal from the locality whenever the people desert affected villages.

45. So far as concerns cholera, our experience everywhere may be said to be complete on the following points, which agree with the deductions from Indian experience by itself as hereafter to be stated:—

(1.) That there can be no manifestation of cholera without the antecedent presence of the epidemic whatever that may be,

(2.) That cholera has a distinct tendency to attach itself and its ravages for a limited time to special localities.

(3.) That the best thing to do at present when cholera appears in a locality is to leave it, and not to go into it until after cholera has disappeared.

(4.) That there is plenty of experience besides that contained in the present Report to prove that this property of localization is always more or less connected with putrescence of organic matter in the subsoil or on the surface.

These simple sanitary facts cover the whole ground practically for India. They can be all dealt with, as indeed they have been, at stations and jails.

The surface can be kept clean, and the subsoil can be drained and so cleansed as to put a stop to well pollution, and if this be efficiently done and constantly attended to there will be little to fear from cholera.

We have not alluded to recent cholera theories, to be afterwards noticed, nor to supposed spread of cholera by infection, for neither enter into the practical sanitary history.

46. We shall conclude these general remarks on cholera in its aspects as an Indian epidemic with the following monthly registered cholera deaths for the whole of India, referring to our memoranda on the provincial reports for the local details:—

Months 1883.	Total Cholera Deaths.	Months 1883.	Total Cholera Deaths.
January	16,588	July	44,877
February	7,265	August	41,395
March	2,427	September	9,584
April	18,697	October	6,165
May	25,549	November	10,891
June	31,991	December	22,952

This abstract shows that the cholera year consists of two epidemic periods, April to August and November to January inclusive. The large increase in January takes place in Bengal.

47. *Small-pox and Vaccination.*—We have already given the small-pox mortality as registered at 232,363 deaths, and it is sufficient evidence of the growing importance of this epidemic disease to state that the mortality from it in 1883 fell short of the mortality from cholera by only 12,013 deaths.

The monthly small-pox mortality for the whole of India was as follows:—

Months, 1883.	Small-pox deaths.	Months, 1883.	Small-pox deaths.
January	16,908	July	20,193
February	21,476	August	10,266
March	30,550	September	5,494
April	33,023	October	4,284
May	36,595	November	5,918
June	29,679	December	12,982

This abstract appears to show that rising temperature is a pre-disposing cause of small-pox.

To cope with this epidemic, the following special vaccination service was employed during 1883:—

Sanitary Commissioners	9
Deputy Sanitary Commissioners	14
Superintendents	44
Deputy Superintendents	20
Native "	260
Average vaccination staff	3,693
Total special staff	4,040

The vaccination and re-vaccination work performed by the special staff was as follows:—

Total vaccinations, primary and re-vaccinations	4,690,257
Successful vaccinations, primary	4,338,508
Re-vaccinations	66,663
Total successful	4,405,171

But besides the work done by the special vaccination staff, there is a considerable amount of vaccination work done by dispensaries all over India. Besides the dispensary officers there were 224 vaccinators attached to dispensaries in Bengal and 28 in the Punjab. The successful vaccinations performed by these institutions in 1883 were 213,991, and of re-vaccinations successful there were 4,866. Classing together the successful vaccination work of both agencies the primary vaccinations numbered 4,552,499, and the re-vaccinations 71,529.

But in estimating the probable protective efficacy of vaccination, the ages at which the operation has been performed are perhaps of more importance than the actual number of operations. The younger the age the more complete is the protection. The tables show that out of the total successful vaccinations performed those under one year of age amounted to 1,734,334, a number which ought to be compared with the births in order to complete our estimate of the real value of work done. Unfortunately we do not know the numbers born in India as a whole. There are various estimates in different provinces, but if we assume a general birth-rate of 34 per 1,000 as sufficiently near the truth for our purpose, we shall find that the population yielding the small-pox deaths ought to yield 6,718,000 births, a number which ought to be compared with the 1,734,334 successful vaccinations under one year of age. The facts show that every effort should be made to extend vaccination at ages under one year. But small-pox is an epidemic, and conforms to the law of unhealthy locality as does cholera, and its predisposing causes must be dealt with locally. The vaccinator's lancet has no power over them.

48. *Fevers.*—The removable causes of Indian fevers are so purely local and personal that we have said all that is necessary about them in the provincial memoranda. It may be a further incitement, perhaps, to more strenuous application of remedial measures, if we state the monthly mortality for the whole of India, as follows:—

Registered Deaths from "Fevers" in 1883.

Months.	Deaths from Fever.	Months.	Deaths from Fever.
January	263,526	July	218,212
February	214,914	August	237,634
March	218,337	September	236,288
April	223,390	October	247,146
May	220,849	November	287,634
June	211,720	December	330,939

There are confessedly grave errors in the fever registration for reasons we have often stated. We know not the precise mortality from fever, but if, for the sake of its teaching, we adopt the year's results of this table, these will represent about 57½ millions of fever attacks, and every such attack represents loss to India and poverty among the people. A correct diagnosis of fever would, no doubt, lessen the blame thrown on this one disease, but, as a general fact, it may be admitted that all the "fever" deaths have been preceded by febrile symptoms, and represent loss wherever the blame be eventually thrown.

49. *Bowel complaints.*—Deaths so classed are generally caused by diarrhœa and dysentery, and as we have given the total monthly deaths from other epidemic diseases, the following abstract may be added for the sake of comparison:—

Month.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	19,986	July	25,737
February	15,978	August	30,863
March	16,328	September	26,709
April	18,009	October	22,972
May	20,057	November	22,357
June	20,286	December	22,325

As a whole, the hot rainy and drying up months yield the highest death-rates from diarrhœa and dysentery, but the deaths in this abstract may be safely estimated as being far below the true mortality.

50. *Injuries.*—Among the 76,059 deaths so registered there were included 8,133 suicides and 23,988 deaths from snake-bite and wild animals, the last representing a loss of useful lives which admits of reduction, especially in the loss from snake-bite. The mortality from injuries in 1883 exceeded that of the preceding year by above 2,000.

51. *All other causes.*—Under this head are included 889,243 deaths, and of these no account can be given. The only remark which appears to be called for on this point is that perhaps further inquiry might do for the whole of India what has been done in the Punjab in rescuing the approximate mortality from pulmonary diseases out of the general confusion. It appears to be time to try at least to improve the diagnosis as well as the registration. Having now concluded our abstract of the year's disease history, we shall state briefly what steps of a preventive character have been taken in Bengal.

52. *Sanitary works, military.*—The following amounts were expended in Bengal Presidency under this head:—

	R.	A.	P.
Original works	2,690,982	14	7
Repairs	2,076,471	15	2
Establishment	1,360,112	5	2
Tools and plant	49,963	11	9
Barrack department	357,794	4	10
Total	6,735,325	4	10

In round numbers the works executed for improving military stations in 1883 may be taken at 670,000*l.*

The works of the year include new barracks at Lucknow, Darjeeling, Peshawur, Quetta, Buxa, Peshin. Cherat is to have new barracks and also other advanced posts. Officers' quarters have been in progress at Quetta and Peshin.

A large Native hospital had been built for the garrison at Rawulpindi, and others were in progress. Several military prisons had been finished, and three gymnasia had been erected.

Improved barrack roofing and flooring, also ceilings, had been provided at many barracks and hospitals. Many commissariat buildings, including bakeries and slaughter-houses, had been erected.

The great military road from the mouth of the Bolan Pass to Quetta was under construction. Under general cantonment works were included the completion of Peshawur water-supply; the extention of Umballa water-supply, water provision for Peshin, and the supply for Chakrata had been begun.

Drainage works for Naina Tal had been carried out, and the drainage of Quetta was in progresss, and also its cantonment roads.

53. There is no information in this section of the Report on the all-important subject of improvement in station details, upon which the health of troops mainly depends; but a certain amount of information on the present condition of 67 cantonments in Bengal Presidency can be obtained from a tabular summary of cantonment reports, which we shall very briefly notice.

We have already seen that the death-rate average for all Bengal stations had fallen in 1883 to 11·21 per 1,000, of which only ·94 per 1,000 was due to cholera. The average of 10 years, 1870–79, had been 21 per 1,000, and in 1880 it had been 27·73 per 1,000. The rate had fallen since then to the 1883 rate, which in its turn was, of course, made up of the average of higher and lower rates.

Some single rates in 1883 were excessive, such, for example, as the rate of *Chunar*, which reached 97·22 per 1,000, but there were only 72 men there. Of course the number is too small to be used for comparison, but when we look at the death causes this view undergoes modification, for we learn from them that seven men died during the year, that four of these deaths were due to cholera, two to enteric fever, and one to diarrhœa, while the 72 men had an admission-rate among them of 1,680·6 per 1,000. Now here, surely, was a case in which an exhaustive sanitary inspection ought to have revealed some cause or other for these results, yet the only one assigned is proximity to the river bank during drying up, to which intermittent fevers are attributed, but these were not the death causes.

Benares yielded a death-rate of 39·89 per 1,000 out of 376 men. One death was due to cholera and two to remittent fever. The death-rate was not due to epidemics, but to more general causes of ill-health.

Dinapore, out of a strength of 932 men, had 25 deaths, or 26·82 per 1,000, but of these deaths seven were due to cholera, seven to enteric fever, and one to remittent fever. In this case it is stated that there are watercourses and reservoirs in connexion with irrigation, which is carried on to a considerable extent around the station, but it is evident that there must have been something else at fault.

In 11 months *Moradabad* lost five men out of 191, and two of the five deaths were due to enteric fever. The death-rate was 26·18 per 1,000. There are tanks within cantonments at this station, and the barracks are defective in ventilation.

Delhi, with 401 men, had a death-rate of 24·94 per 1,000. Out of 10 deaths in this station two were due to enteric fever and one to intermittent. The local position of the fort and cantonments on the banks of a large rising and falling river is assigned as a local disease cause.

Shahjehanpur had a death-rate of 23·61 per 1,000 out of 210 men.

We have noticed these stational death-rates as being most largely above the average of the Presidency, merely to show the necessity of making minute practical inquiry into causes and remedies. Speaking generally, the cantonment notes show want of drainage and other causes of water-logging. In some cases defective conservancy arrangements and need of greater care in disposal of sewage. Some water sources were found impure. But there are also evidences of progress in sanitary work.

Muttra, out of 341 men, lost only one by death, and the cause is not assigned. The record of sanitary work at Muttra stands as follows:—Several drains for bath and ablution water were formed of masonry. Barrack bungalows were re-roofed and their ventilation improved.

The lesson which appears to be taught by the present state of these cantonments, so far as can be gathered from the report abstracts, is that since the general death-rate of the Bengal European Army has fallen, and as further reductions appear to be dependent on carrying out sanitary work, especially subsoil drainage, that the stations yielding the highest rates from cholera, fevers, and bowel diseases

should be taken in hand and dealt with as the chief offenders. Effort in this direction is in strict accordance with the true principles of sanitary economy, which teach us that where means are limited they should be expended where they are most required.

54. *Sanitary works, civil.*—In our memoranda on the separate provinces we have given the chief results of the year under this head, but we may here state that sanitary work is further advanced in the Punjab than in any other Government. Everywhere, however, the work has been chiefly confined to towns and municipal districts, and we fear that the view of the Sanitary Commissioner, where he says that "very little appears to have been done during the year to improve the sanitary "condition of villages in Bengal," is one generally applicable.

55. *General remarks.*—This head, which forms the 10th section of the Report, is devoted to a discussion on the supposed "cholera bacillus" and its relation to cholera. The subject is so thoroughly used up that it would scarcely require notice, were it not that it involves errors which may at any time be reproduced to the detriment and misdirection of sanitary work. Even in the present case a public attack was made at the International Health Exhibition on the Indian sanitary service, on the ground that its discouragement of theoretical discussions had probably prevented the Indian medical service from discovering this same cause of cholera, and it need scarcely be said that all the theorists received Dr. Koch's bacillus thankfully as a vindication of their standpoint.

As this matter forms part of the present Report, and also of a separate publication of Dr. Cunningham on "Cholera, what can the State do to prevent it?" which is in reality an appendix to the Report, we shall briefly notice the discussion as part of the year's sanitary record. Ever since cholera appeared in the West attempts have been made by the use of microscope and by other methods of inquiry to obtain some knowledge of the pathology and etiology of the disease, and these attempts have ranged themselves under two classes, those cases,—namely, in which only a record of the observations was kept for future use, and those in which observations, sometimes of a trivial character, were made the basis of a theory about cholera, its treatment and prevention. Observations of the first class have always been of use, even negatively, while those on which theories have been founded have been soon set aside for others apparently more plausible, but they have also done mischief by placing the theoretical element in the foreground of the question, to the detriment not only of advance in real knowledge but to the adoption of suitable measures of prevention. We may select a case or two of each class to illustrate this matter. During the cholera invasion of 1848–49 certain minute organisms were discovered by the microscope in choleraic matter which were supposed to be new, and they were considered by many persons to be the germs of the disease. This was, however, merely a mistake in interpretation, because the objects had another origin altogether. During the cholera of 1854–55 the General Board of Health appointed a Committee to take up the microscopic part of the work, and they discovered and figured similar microscopic objects in cholera excreta, bad water, and impure air.

They however applied the necessary test of inquiring whether these microphytes were peculiar to cholera, and they found they were not so. They were vibriones of not uncommon occurrence, and hence it could not be inferred that they had any causative relation to cholera, but even this negative result was of importance.

At a later date an observation, and a theory founded on it, attracted much attention, namely, the rice fungus theory of Professor Haffer, of Jena. This theory had a certain importance, because it led to the first detailed microscopic inquiry in India, which was ably carried out by Drs. Lewis and D. Cunningham, with the result that the rice fungus theory was completely disproved, and a large amount of interesting information on the minute pathology of cholera, and on the relation of soils, subsoils, air, and water impurities to the epidemic was obtained. In this case no theory was enunciated, only facts were recorded, and these remain with all their value for future use.

The latest investigation at Calcutta by Dr. Koch and his colleagues resulted in obtaining facts, and in founding on them a theory about the cause of cholera, which has since been called in question, apparently because the same tests were not adequately applied during the inquiry as were made use of by the London Committee in 1855. Beyond doubt the German Commission discovered in cholera cases, and in certain water tanks, a very minute curved microphyte to which they gave the name *bacillus*, although equally high authority in this country has pronounced the organism to be a spirillum. This, however, is of small moment in the discussion, because it has been since affirmed by Drs. Klein and Gibbes, who were sent by the India Office to continue the investigation independently at Calcutta, that the microphyte is not peculiar to cholera cases (just as in 1855 the same thing was proved in regard to vibriones), that the use of water containing it was not necessarily followed by attacks of cholera, that cholera cases showed themselves where the water was quite pure and free from these bodies, and, moreover, Dr. Lewis has since shown that the same, or a similar *bacillus*, is an abundant inhabitant of the mouths of healthy persons, especially of children, far away from any cholera district. Dr. Koch has since denied the validity of these observations, and we must wait the results of further investigation and discussion before arriving at any conclusion on the matter. We have only to add, that in none of the inquiries has it been found possible to communicate undoubted cholera to any animal by cholera material, and there is not a single instance on record of cholera having been accidently communicated in this way to man, notwithstanding the continual practice of postmortem examinations.*

56. We have thought it necessary to make this statement, not for the purpose of throwing discredit on legitimate attempts to extend our knowledge on a subject of great importance, but simply to point out that, up to the present time, these inquiries have afforded us no help in understanding what cholera is and how human life can be saved. We may, therefore, set them aside, and take up the question on the ground of experience gained in this country, and where Dr. Cunningham has taken it up for India in the present Report.

* And recently of sub-cutaneous inoculations in Spain on a very large scale.

57. Amidst all the diversities of opinion which have existed about cholera, there is one circumstance, the importance of which cannot be over-rated, and this is that, ever since cholera appeared in the West, its incidence among any population has been acknowledged simply as matter of every day experience to be related to the conditions of life in the affected places. So much has this been the case that it has long been known that leaving affected dwellings ensured the comparative immunity of their inhabitants, while the removal of unhealthy local conditions kept the epidemic in abeyance. The proof of these laws, long known in the West as regards cholera, has been obtained during the 20 years of Dr. Cuningham's service as Sanitary Commissioner for India, and in the present Report and its Appendix he has sought to enforce their supreme importance as including the only real principles of action on which any dependence for safety can be placed.

There is nothing new in the proof. He has merely brought under one view the continuous every day experience passing under his eyes, and such as it has been set forth year after year in sanitary reports from all parts of India. So that there is now a continuous invariable testimony on the subject from every country where cholera has appeared, but, as men's minds are not all alike, there have been at the same time not facts, for there are no facts, but beliefs, on the subject which have led to dependence on restriction of human intercourse as the sole means of preservation against epidemics. This matter enters also into Dr. Cuningham's discussion, but, as the whole of it has been discussed to an extent almost beyond its importance, we shall merely state the general result of this immense Indian experience:—

1st. That to which we apply the name of "cholera" is only an effect of a cause of which we know nothing. All we can do practically is to study the effect and its relations.

2nd. As the presumed cause must precede the effect, it may exist without making its presence known. It is this cause to which the empirical name of "epidemic" is applied.

3rd. We can conceive this epidemic cause as being so intense as to destroy all life, or as being so feeble as not to show its presence. Practically, however, it is consistent with every day experience to state that it always manifests itself where certain local and personal conditions exist, and hence that the epidemic law can only be studied through local epidemic incidence.

4th. On this fact is founded the whole science of epidemic statistics, and, if we desire to obtain any practical information on the subject of cholera, the first thing to do is to master the statistical evidence. This point is fully discussed by Dr. Cuningham. He has confirmed the previous view of Dr. Bryden, that there is an endemic area within which cholera is always present in varying intensity in different districts of it, and at different seasons; that cholera appears far outside this area, and in Bengal always moves up, and never down, the great rivers; that the movement has no relation to river traffic, or to railways, roads, or any movements of population, and he supports this view by the following curious facts, which, on certain favourite methods of reasoning, would show that railways were protective against cholera.

Average annual cholera death-rates per 10,000 of population for a period of 12 years:—

Districts away from the Line of Railway, and comparatively difficult of Access.		Districts on Line of Railway.	
Azamgarh	11·17	Allahabad	7·37
Gorakhpur	12·65	Futtehpur	5·06
Basti	22·60	Cawnpore	5·13
Gonda	19·38	Etawah	3 67
Bahraich	14·97	Unao	7·04
Kheri	14·45	Lucknow	8·88

This 12 years' contrasted experience shows that cholera depends for its movement on some other agent than human intercourse, and also that the intensity of the epidemic as evidenced by the death-rates varies greatly in different regions of the country, for we can scarcely suppose that the sanitary conditions varied so greatly as to account for the great difference in death-rates.

He shows further that, as has been known all along, a cholera epidemic moves in a certain definite direction, and that persons advancing in the same direction may apparently yield the first cases of cholera where they stop, whereas if they turn aside out of the stream they may die, and no one else may suffer near them. Cholera-infected regiments have moved against the epidemic current without spreading cholera. If they marched with it they might appear to carry the disease.

58. In a country like India, where all localities are bad, it is difficult to find exceptional cases, but it is certain that cholera swoops down on bad insanitary localities, and, as we have already shown, the prevalence of cholera in stations of British and Native troops, in jails and in large cities, has been greatly reduced by sanitary works and measures. Bad localities have been converted into good ones, and have comparatively escaped, yielding perhaps the best form of proof.

On the contagion side, on the other hand, these 20 years' experience have failed to yield any evidence of the spread of an epidemic by human intercourse, or of the arrest of an epidemic by any quarantine procedure. Practically, therefore, the whole epidemic history resolves itself into a local question. Keep localities occupied by population groups in a wholesome condition, and there will be little to fear from cholera. If this has not been done the safest way is to leave the locality for the time. And care should always be taken not to enter a place where cholera is known to be present.

59. The conclusion of the whole matter is that so-called sanitary administrations should cease to waste their strength on impossible and useless restrictions on intercourse, and Dr. Cuningham

concludes, as the first general Board of Health in this country concluded after the experience of 1848–49, with these words:—"Once accept the great principle that the improvement of local "conditions is the one and only principle on which the State can act with advantage in matters of "public health, and the solution of the whole question will be comparatively easy. Sanitary "administration will then no longer attempt to accomplish impossibilities, but will be directed to "those great practical reforms which cannot fail to improve the health, and thereby add to the "happiness and prosperity of the people."

60. This conclusion, which Dr. Cuningham has set forth as the end of 20 years of most useful and important public health work in India, although specially referring to cholera, includes the future principles of Indian sanitary improvement. After the experience already obtained in dealing with sanitary problems at British and Native stations, in jails, and among certain groups of the civil population, it is no longer possible to ignore or to under-estimate the importance of the facts in their bearing on Indian sanitary progress and work; and in order that those supplied by Army experience may not be overlooked or forgotten, we shall conclude our notice of this, which is Dr. Cuningham's last Report for India, by a brief historical statement of the facts.

61. The Report of the Royal Commission on the Sanitary State of the Indian Army, which was issued in 1863, contained two estimates of Army mortality. A death-rate of 69 per 1,000 was described in the Report as the figure round which the death-rates of the Company's troops during the years from 1800 to 1856 has oscillated. The other statement, referring to the mortality of troops of the line, was laid before the Commission by the late Sir Alexander Tulloch. It was extracted from the War Office returns for the years from 1817 to 1855, and gave the annual average death-rate for the whole period as 70 per 1,000. These were the rates for the reduction of which sanitary works and measures had to be devised and executed. For this object the Royal Commission immediately on its appointment in 1859, sent instructions involving sanitary procedure for inquiries to be made at every station in India, and two results followed. A very complete account of sanitary condition was obtained, and improvements were begun. The Royal Commission further advised that the experience obtained by the Commission for improving barracks, hospitals, and stations at home should be used in dealing with the corresponding Indian problems. The Commission was reconstituted for the purpose, and became the Army Sanitary Commission, and the India Office requested it to prepare a Code of "Suggestions" for Indian stational improvements. This was issued in 1864, and circulated all over India for the information of local officers in drainage, water-supply, barrack and hospital construction, &c. One section of it gave details for the registration of deaths in India. And our Commission has continued since then to give advice and assistance on all sanitary questions and details referred to it. The Code was revised at the request of the Government of India and the India Office, and re-issued in 1882.

62. In estimating the possible saving of Army life, the Royal Commission considered that the death-rate of 20 per 1,000 ruling among Indian civil servants ought to be attainable for soldiers by the application of ordinary sanitary methods. But they went beyond data of this class, and drew pointed attention to sanitary work which must in time be done, while they expressed a hope that when the stations and their vicinity were brought under proper sanitary regulation "the natural "death-rate in times of peace of men of the soldiers' ages in India will be no more than 10 per 1,000 "per annum."

63. We have already shown how the death-rates have been falling under sanitary work in years of peace, and how they are temporarily raised in war years. But we have now arrived at this point, that up to the time of the Royal Commission of 1859 the station death-rates in India had been on an average 69 and 70 per 1,000, while in 1883 the rate was 10·88 per 1,000 for the whole Indian Army.

The death-rate of a single year cannot, however, be accepted as an indication of permanent improvement. An epidemic of cholera might very soon raise it for the time. But any neglect of sanitary measures or any surrender of the ground already gained would necessitate both labour and expenditure to regain it. What has now to be done is, not only to keep what has been got, but to improve on the acquisition, and we have called pointed attention already to the direction in which future sanitary work should be carried out at the stations.

64. The Appendix to Dr. Cuningham's Report contains the usual indispensable statistics prepared by Dr. Stephens, besides two interesting reports on an expeditionary force in Assam in 1883–84, and on the Indian division of the Egypt expeditionary force in 1882. Both these reports are departmental, and do not call for remark.

65. In conclusion, it is matter for congratulation to all interested in public health improvements to find from this 20 years' experience that sanitary measures lose none of their efficacy in warm climates. They have done more for the Army in India than for the Home Army merely because there was more to be done, and what has been accomplished for the Army can, beyond a doubt, be done in its degree for the civil population. When the work at home was begun, the healthy rural population of England was assumed as affording an attainable health standard for the army. Now in India we can hold up the Army, British and Native, as affording a health standard to be aimed at for the country population. The work for this vast population has to be done, and can be done, and in our "Suggestions" we have pointed out the way.

21st July 1885.

No. 2.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for Madras for 1883.

This report contains less sanitary information than usual, and the public health part of it is mainly confined to figures, the relation of which to disease causes and their remedies has been passed over apparently from delay in the receipt of information, and with regard to one very important subject, the severe cholera epidemic of 1883, no details are given. They had been received, but were so voluminous that time was required for their consideration. We are, however, promised some account of this epidemic in a separate form.

It is necessary to refer to these matters, to account for the absence of detailed information in the present Memorandum on the chief diseases of the year.

2. The population of Madras Presidency, according to the census of 1881, and exclusive of Europeans and Eurasians, was 30,835,771,; but the population making returns of births and deaths is given at 28,503,100.

3. The registered births among this population were made up of—

Males	404,937
Females	386,837
Total	791,774=27·7 per 1,000.

The relation of this birth-rate to those before and since the famine of 1877–78 shows some points of interest as follows :—

Years.	Birth-rates per 1,000.	Years.	Birth-rates per 1,000.
1876	21·6	1880	22·9
1877	16·3	1881	25·5
1878	11·9	1882	26·0
1879	16·4	1883	27·7

Up to 1876 the birth-rate registration had been improving. The famine set in severely in 1877, and there was an immediate drop in the numbers registered, partly because the registration fell off during the famine; but of recent years the numbers born and the births registered appear to have increased, although the birth-rate registered in 1883 can scarcely be accepted as the true rate. For the last four years, however, the birth-rate has been steadily rising. In several districts the registered birth-rate exceeds 3 per cent., and in one district it exceeds 4 per cent. of the population.

4. In 1883 there were registered the deaths of—

Males	278,485
Females	263,445
Total	541,930

equal a death-rate of 19 per 1,000 on the registering population, a rate evidently below the truth, especially as 1883 was an epidemic year. Assuming the same eight years' period for the death-rates as for the birth-rates, and including the famine years 1877–78, we arrive at the following comparative results :—

Years.	Death-ratio per 1,000.	Years.	Death-ratio per 1,000.
1876	23·3	1880	15·2
1877	53·2	1881	16·2
1878	27·8	1882	16·2
1879	18·9	1883	19·0

When the district death-rates are compared with each other, they present little uniformity. The lowest was 13·1 per 1,000. 13 districts out of 32 registered death-rates under 2 per cent., and one district only made returns of 38·1 per 1,000, not too high a figure for an epidemic year.

The result shows that neither birth nor death rates for the whole province are known, although it is probable that the town rates are more reliable. Divided between the town and country populations the death-rates were for—

Towns	24·9 per 1,000
Country	18·6 „ „

5. We shall next show the relative mortality from assigned death causes among both classes of population:—

Diseases.	Ratios per 1,000.			Total Population.
	Total Deaths.	Towns.	Country.	
Cholera	36,284	3·8	1·1	1·2
Small-pox	37,975	1·6	1·3	1·3
Fevers	203,786	5·4	7·2	7·2
Bowel complaints	22,098	2·1	·6	·7
Injuries	11,509	·3	·4	·4
All other causes	230,278	11·7	7·8	8·0
All causes	541,930	24·2	18·6	19·0

For reasons already stated, we have no means of discussing the sanitary history of any of these diseases, and what follows relates to the statistical data which are not altogether reliable.

6. We shall next discuss the statistical data for each disease, beginning with *cholera*.

Cholera prevailed in various degrees of severity in all the districts of the presidency, with three exceptions, Vizagapatam, Kurnool, and South Canara, from which no cholera deaths were returned. In the 19 districts invaded by the epidemic, it prevailed in various degrees of intensity. The north-eastern districts returned very few deaths. In Vellore, Madras, and Chingleput, the epidemic did not appear in force till towards the end of the year. Its course was nearly the same in Cuddapah, Bellary, Anantapur, and North Arcot. But in several districts it appeared as a severe epidemic during every month of the year, and most of the mortality fell on South Arcot, Trichinopoly, Tanjore, Madura, Tinnevelly, Salem, and Coimbatore. Of the 229 circles of registration in all the districts, the cholera mortality was returned from 142 only, and out of 52,051 population groups all the deaths were furnished by 4,413, or under 8½ per cent. of the number; but the proportion of registration circles, as well as of villages attacked, varied according to the intensity of the epidemic, of which, indeed, they supplied an index.

Thus in the seven most severely affected districts, already indicated, cholera prevailed in all the 71 registration circles, with only two exceptions. The same districts contain 16,773 villages, of which 3,859 suffered, or above 20 per cent. of the number.

The epidemic of 1883 repeated the same law of cholera, namely, that it is not generally diffused over a country; that it is greatly more severe in some localities than in others; and that the mortality of any given year depends on the number of population groups attacked, and on the number of deaths in each.

7. Of the deaths from cholera in 1883 the town population of 1,696,075 yielded 6,436 deaths, or 3·8 per 1,000, and the country district population of 26,839,745 returned 29,816 deaths, or 1·1 per 1,000, a ratio which directly raises a question as to whether all the country deaths were returned. Considering the sanitary state of the village populations, the reply must apparently be in the negative.

8. The monthly cholera deaths registered, were as follows:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	3,671	July	2,248
February	1,826	August	1,293
March	1,392	September	628
April	1,007	October	1,347
May	497	November	6,143
June	1,168	December	15,164

This monthly record presents some facts which differ materially from those of ordinary epidemic years. It almost appears as if the first eight months showed the breaking up of one epidemic, to be succeeded afterwards by another of great and unusual intensity, which would pass over to the following year. Such an occurrence would be in conformity with the past history of cholera in Madras, as will be gathered from the following annual deaths registered during the last 18 years:—

Years.	Deaths from Cholera.	Years.	Deaths from Cholera.
1866	200,261	1875	24,546
1867	38,205	1876	249,193
1868	8,036	1877	337,430
1869	21,034	1878	47,167
1870	55,867	1879	13,296
1871	15,956	1880	613
1872	13,247	1881	9,446
1873	840	1882	23,604
1874	813	1883	36,284

On the supposition that the registration of cholera deaths in this table has been fairly correct for the 16 years, we are led to the conclusion that during the last eight years of the series the deaths from cholera have been more than double the number of the first eight years, and even if the enormous death-rate of the famine year 1877 be left out, we should still have to deal with an increased death-rate during the last eight years of the series.

9. It follows, as a matter of course, that no sanitary work which has been done in the towns and villages of Madras Presidency has materially influenced local conditions during the whole 18 years taken at least over the entire population. There are exceptional cases which add stronger proof to the rule that cholera is a test of the health conditions of localities in Madras Presidency, as it is everywhere, for we only know cholera through its manifestations in localities, and we have as complete proof as can be obtained of what the sanitary condition of affected towns and villages really is, and this knowledge leads us directly to the practical remedies required; but beyond this conclusion the statistics tell us that no progress has been made, except perhaps in a few places, in applying the results to practical purposes.

10. *Small-pox.*—High as was the loss of life from cholera in 1883, it was exceeded by the loss from small-pox, which amounted to 37,275 deaths, or 1,691 more than by cholera mortality. Of these deaths, 7,573 were registered as under 1 year of age, 15,736 between 1 year and 12 years of age, and 14,666 at ages above 12 years. Small-pox prevailed as an epidemic over the entire area of the presidency. Every district registered deaths from it, and out of 229 circles of registration 218 were affected. The number of attacked villages cannot be given, but out of 76 towns 60 returned deaths. The country death-rate was 1·3 per 1,000, and the town rate 1·6 per 1,000.

11. The deaths, month by month, were registered as follows :—

Months.	Small pox Deaths.	Months.	Small-pox Deaths.
January	3,519	July	2,623
February	4,489	August	2,378
March	5,429	September	1,706
April	4,161	October	2,041
May	3,309	November	2,000
June	2,594	December	3,670

12. *Vaccination.*—The following was the staff during the year :—

Inspector of vaccination	1
Deputy inspectors, 1st class	32
" " 2nd class	9
Vaccinators, 1st class	254
" 2nd class	373
Probationers	115
Peons	39
Total staff	823

13. The work done by this staff during the year may be summed up as follows :—

Total number vaccinated	735,808
Primary vaccinations	720,349
Of which successful	669,738
Re-vaccinations	15,459
Of which successful	6,976

The protective agency of this work will be better estimated by the following data :—

Average ratio per 1,000 of population vaccinated successfully in five years	16·2
Average five years' deaths from small-pox per 1,000	·8
Births, 1883	791,774
Successful vaccinations under one year of age	127,952
Percentage of successful vaccinations under one year to the year's births	16·
Deaths from small-pox under one year, 1883	7,573

This abstract shows clearly where the vaccination service in Madras Presidency is defective. It is not possible to make any serious impression on small-pox mortality, so far as this can be influenced by vaccination, as long as only 16 per cent. of the children born are vaccinated within a year after birth. The explanation of this state of matters given by the Sanitary Commissioner is that the educated native classes treat the disease with supreme indifference, and that the poor look upon small-pox cases as beneficient marks of their goddess, and are deaf to persuasion in the matter. Of course such a state of feeling can only be overcome by education and advance of knowledge. But it must not on this account be forgotten that small-pox in Madras is an epidemic disease, and like all other epidemics it is influenced in its greater or less intensity by local causes. It is by no means an

occasional visitant, as will be seen by the following abstract, giving the deaths registered from it for the last 13 years:—

Years.	Small-pox Deaths.	Years.	Small-pox Deaths.
1871	20,823	1878	56,360
1872	39,074	1879	17,840
1873	51,782	1880	14,529
1874	48,343	1881	15,776
1875	24,375	1882	20,159
1876	23,469	1883	37,975
1877	88,321		

In the present state of public opinion on the subject of vaccination, it is not likely that these figures, with their recurring years of aggravations (including famine, which always augments the death-rate), will be materially reduced by the vaccination service, although one obvious result of the data as a whole is to point clearly to the necessity of concentrating effort on the vaccination of infants. But when taken in connexion with the cholera mortality they strengthen the conclusion that both epidemics are at present very unnecessarily aggravated by the neglect of sanitary measures. If these were pressed forward more rapidly the vaccinator's work would probably be more effectual.

14. *Fevers.*—The next abstract gives the registered fever deaths for 18 years.

Years.	Deaths from Fever.	Years.	Deaths from Fever.	Years.	Deaths from Fever.
1866	110,102	1872	214,148	1878	374,443
1867	112,311	1873	222,843	1879	285,477
1868	105,692	1874	226,220	1880	209,940
1869	132,846	1875	252,962	1881	203,542
1870	151,027	1876	230,692	1882	188,561
1871	192,469	1877	469,241	1883	203,786

This table bears marks of improved registration as to numbers at least. The nomenclature, however, is not trustworthy, but on the supposition that such errors are more or less constant, these annual data appear to show, like those for cholera and small-pox, that little has yet been accomplished in Madras Presidency to cope with epidemic death-rates. The great rates of 1877 and 1878 afford us no ground for hope in this matter, for the rates of these years included the increased liability to fevers which accompanied the famine. How little we have to expect at present may be learned from the following statement in the Report under review:—"When the poor people learn how to protect "themselves by proper clothing and food from rapid changes of temperature, then the muster roll "of deaths from fever will diminish."

15. It is necessary to say, however, that this is begging the whole question as to the cause of paroxysmal fevers, and the relation of these fevers to the prosperity of the country, and another question has first to be answered, namely, how comes it in such a country as India that there is a deficiency in food and clothing? The reason is not far to seek, and we may ask, with our present knowledge of these fevers and their causes, whether any amount of food or clothing ever prevented a single case? Do Europeans never suffer from these paroxysmal fevers? The real fact is, that we have no proof that defects of this class ever caused a case of ague. The disease must be there first, and being so, its severity may no doubt be augmented by deficiency of clothing and food, changes of temperature, &c. But European every day experience in India shows that no amount of personal advantages of this kind can keep away intermittent or remittent fever. The present Report indeed states that during the last six years there had been 11,735 cases of intermittent fever among European troops who are in want neither of proper food, clothing, nor shelter. What they really need is, that the local fever causes about stations should be dealt with.

16. The object of these remarks is simply to point out the danger of dealing with great and well known general and local causes of fevers and other epidemics as if these depended for their severity merely on personal advantages or wants.

The sanitary rule in such matters has been long known, and it is this, first reduce the prevalence of disease by improving the dwelling and its surroundings; on this there will follow improved stamina and greater ability to work, besides improved habits of life, and, as a matter of course, there will be better food and better clothing, and these in their turn will further improve general health.

To place the last elements first is simply to say in effect that improvement by the people themselves is impossible. The case as it stands is as complete as it need be, and it all tells in favour of action on the part of Government in rooting out those local causes which are known by experience to be the real causes of Indian poverty. How the work can be done most effectually it is for the Government to decide.

17. The monthly prevalence of fever among the civil population was as follows:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	13,415	July	18,249
February	15,885	August	18,579
March	15,097	September	16,808
April	14,235	October	16,210
May	15,042	November	17,789
June	14,814	December	22,668

Fevers appear to have been most prevalent during the drying up and variable and low temperature months. The fever death-rate for the country districts was 7·2 per 1,000, for the towns 5·1 per 1,000, and for the Presidency 7·1 per 1,000.

18. *Bowel complaints.*—Deaths registered under this head were reported from all the districts, and from 225 out of 229 circles of registration. All the 76 towns, with 9 exceptions, registered such deaths. The district death-rate was 0·6 per 1,000, and that for the towns 2·1 per 1,000. The rate for the whole Presidency was 0·7 per 1,000, against a previous five years' rate of 0·9 per 1,000.

The monthly deaths registered from bowel complaints in 1883 were as follow:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	1,901	July	1,946
February	1,481	August	2,273
March	1,346	September	1,991
April	1,296	October	1,884
May	1,448	November	2,352
June	1,551	December	2,879

There is nothing specially calling for remark under this head.

19. *Injuries.*—This section of the tables includes 1,477 suicides, 340 deaths from wounding, 6,874 from accidents, and 2,318 deaths from snake-bite and wild beasts. In all, 11,509 violent deaths.

20. Deaths from *all other causes* numbered 230,278, or 8 per 1,000 out of a total death-rate of 18·9 per 1,000. Of these death causes nothing is known.

21. We shall conclude this notice of the disease history of 1883 with the following comparisons:—

Deaths from cholera, 1883 - - - - - 1·2 per 1,000
" " " previous five years average - - - ·6 "
Deaths from small-pox, 1883 - - - - 1·3 "
" " " previous five years " - - - ·8 "
Deaths from fevers, 1883 - - - - - 7·1 "
" " " previous five years " - - - 8·7 "

Fever mortality is uncertain, for reasons already stated, but cholera and small-pox, which are well known diseases, both show increase, and confirm the view already stated that no impression has yet been made on the epidemic susceptibility of the people.

22. Section VIII. of the Report is devoted to the Army and to the stational reports. We have dealt with the questions in this section on other papers, and we shall only touch briefly on the leading facts for the year.

The strength of European troops on 1st January 1883 was 11,528. In the course of the year there was an increase of 1,930 and a decrease of 2,684, leaving the strength on 1st January 1884 at 10,774.

The following were the sanitary statistics for 1883, in ratios per 1,000 strength:—

Admissions - - - - - - 991·0
Daily sick - - - - - - - 59·7
Deaths - - - - - - - 10·0
Invalided for change - - - - - 20·1
" " discharge - - - - - 13·6

These data show very considerable advance in the sanitary state of Madras stations, but there are still several important stations at which works have to be carried out. These we have dealt with on other papers.

23. *Native Army.*—The medical returns of this army refer only to 24,998 men, and the ratios per 1,000 from inefficiency causes were the following in 1883:—

Admissions - - - - - - - 693·9
Daily sick - - - - - - - - 27·7
Deaths in and out of hospital - - - - 12·4
Invaliding - - - - - - - 26·9

The admission-rate of 991 per 1,000 among European troops includes 243·2 per 1,000 from venereal diseases, which, if deducted, would bring the rate nearer that of the Native Army. The

daily sick and invaliding of the Native Army are both lower, but the death-rate was 2·4 per 1,000 higher than that for European troops.

24. The statistics are followed by a very brief abstract for each of 27 stations occupied by troops. There is nothing in them calling for remark, except the account given of surface sanitary work, which is on the whole satisfactory.

It is apparently in this important matter, and especially in conservancy, that the chief advances in the way of improvement have been made. Of sanitary work proper nothing is reported, except digging a few wells and improvements in surface drainage. We have on other papers called attention to the apparent causes of unhealthiness at several stations, but if the death-rates be averaged over all the stations, there is not much to complain of in this matter. Only the higher rates at the larger stations show in what direction sanitary work is required, and if these matters be attended to, the death-rate of the Madras European Army ought to fall below 10 per 1,000.

25. *Sanitary works, civil.*—The first subject dealt with under this head is the sanitary condition of the Madras jails, which presents some points of considerable interests in their bearing on the sanitary improvement of the civil population generally. The best way to show this relation will be to quote from the Report the following data :—

Years.	Admissions per 1,000 of Strength.	Deaths per 1,000 of Strength.	Years.	Admissions per 1,000 of Strength.	Deaths per 1,000 of Strength.
1861–62	1,502·6	93·0	1873	599·8	28·2
1862–63	1,319·0	69·4	1874	714·1	26·6
1863–64	1,378·6	107·6	1875	752·6	38·7
1864–65	1,491·1	101·5	1876	705·6	42·4
1865	2,390·6	156·8	1877	921·3	175·4
1866	1,249·7	124·5	1878	944·4	125·4
1867	1,012·4	53·9	1879	890·5	55·8
1868	869·1	33·8	1880	854·0	44·7
1869	804·7	41·2	1881	742·5	41·4
1870	735·2	26·5	1882	806·4	44·9
1871	779·9	17·9	1883	865·3	29·4
1872	681·1	22·2			

Up to 1867 the casualties were enormous; but strenuous efforts in the way of improvement were begun about that time, and everything was slowly improving until the famine intervened. This intercalated event gave rise to a very great increase in the jail deaths in 1877–78; this rise was due not to any sanitary retrogression in the jails but to the state of the prisoners on committal, and as the rates continued high during the succeeding years, the figures may be taken as showing that the civil population continued to suffer from the effects of the famine for several years after. The satisfactory point proved by the table is that jail improvements are making progress, and that among a section of the civil population removed and separated from the general mass, it is possible to act both on the sick and death-rates by sanitary work.

26. Another table in the Report gives the deaths from cholera, dysentery, diarrhœa, dropsy, and anæmia for the same years, but instead of quoting this table entire, it will be sufficient for our purpose to give the first and last lines of it :—

Years.	Deaths per 1,000.				
	Cholera.	Dysentery.	Diarrhœa.	Dropsy.	Anæmia.
1861–62	26·3	8·5	14·6	—	—
1866	—	—	—	5·3	12·1
1883	1·9	3·8	5·8	1·5	·5

These contrasted figures appear to show improvement in all the elements of jail management; but the data show also the influence of epidemic intensity on the amount of cholera in jails. There were in all 15 deaths from cholera, nine of which took place among 176 prisoners in Cuddalore Jail, and this jail is situated in South Arcot, which was one of the most severely attacked districts in 1883. It yielded 5,742 deaths from cholera.

27. *Municipalities.*—Excluding the town of Madras, which has a local Act, there are 47 municipal towns, with an aggregate population of 1,729,848, administered under the Towns Improvement Act III. of 1871. Many of these towns have thus been in the hands of the improver for a term of years, and the statistics ought to show us what advance has taken place in the public health.

The following are the data in the Report under review:—

Years.	Total Cholera Deaths.	Total Small-pox Deaths.	Total Fever Deaths.	Death-rates per 1,000 all Causes.
1869	2,048	303	6,359	21·4
1870	3,505	586	6,913	22·0
1871	1,447	1,484	8,403	25·1
1872	716	2,660	9,762	26·6
1873	47	3,913	8,660	27·4
1874	30	2,265	8,874	28·4
1875	7,818	1,161	9,749	32·8
1876	2,430	2,086	8,576	32·8
1877	19,631	11,592	14,049	31·3
1878	3,794	2,908	14,485	33·5
1879	672	2,091	13,182	29·8
1880	36	1,892	11,298	26·6
1881	1,931	2,349	11,274	28·1
1882	3,612	2,392	9,947	28·0
1883	4,878	4,555	10,366	30·0

The earlier years in this list show defective registration, but it cannot be said of the death-rates of the latter years, especially when these are considered with the great losses of life from the common epidemics, that the municipally regulated towns show much advance in real sanitary protective work taken over the whole. Some individual towns show better results than others, but the work done, whatever it may have been, appears to have made little impression on the death-rates, especially from epidemics.

28. The following were the amounts spent for sanitary measures by these towns during the year 1882–83:—

	Rs.
Conservancy	328,870
Improving town sites	30,994
Water-supply improvements	23,693
Fairs and festivals	3,469
Markets, slaughter-houses, &c.	13,678
Other sanitary objects	46,448
Total	447,152

or about sixpence per head of the population.

29. The Sanitary Commissioner describes the year's works as follows:—"They consisted in the "main in the repairing and cleansing of tanks and wells, latrines, drains, dustbins, markets, and "slaughter-houses, in the removal of prickly pear bushes and other rank vegetation, in the con- "struction of latrines, drains, and dustbins, and in sinking of a few wells, and in some other minor "works."

More attention is being paid to drainage and water-supply in some towns than in others. Conservancy is done as usual, and the important step has been taken by several municipalities of carrying out private scavenging including that of the backyards of native houses. This is a step in the right direction, but it should be accompanied by provision for cattle to be removed from these compounds.

29. Details of sanitary work are given for 17 municipalities, which do not require separate discussion except in so far as they afford information on the sanitary condition of the towns, but in this direction they afford some useful details.

The town of *Bellary* has a population of 53,460. Its registered death-rate in 1883 was 22·9 per 1,000, and its quinquennial rate was 30·4 per 1,000. There was very little cholera in the district, and the death-rate from this epidemic was 0·1 per 1,000. The district fever-rate was 5·8 per 1,000. The town epidemic rates were about double those of the surrounding country; for the town population had a cholera death-rate of 0·2 and a fever-rate of 9·9 per 1,000. The question naturally suggests itself whether these double rates have any connexion with the following account of the water-supply? It is obtained "principally from the fort ditch and a large rain-fed tank. Besides "these there are a number of minor tanks and wells, some with good and others with brakish water." Again, as regards drainage, we are told that it "is defective. No improvement since last report. "Numerous cesspools exist." Have we not in these brief statements the elements described of radical unhealthiness?

30. A similar account is given of the drainage of *Adoni*.

31. Of *Conjeveram*, a great pilgrimage place, which of late years has been kept free of cholera or nearly so by active conservancy, it is satisfactory to be told that "a gradual improvement is observable "in the sanitary condition of the town." But the public health cannot be considered as safe where "sewage flows into the backyards of houses and sinks into the soil," and where some of the tanks belonging to temples "are subject to all kinds of pollution, nor are the wells free from it."

32. Of *Coimbatore*, it is said that "a good drainage system for the whole town is required. Drainage of houses runs into the main drains which flow into a tank not used for drinking purposes. What becomes of it? Would it not be advisable to try application of it by irrigation as a temporary remedy till the town is drained?

33. The town of *Eroda*, with a population of 9,864, may be adduced as an example among many others that a good water-supply by itself is no sufficient protection against cholera. Its death-rate in 1883 was 29·9 per 1,000. It lost 71 of its inhabitants by cholera, a rate of 7·1 per 1,000. Its water-supply is reported as "good and ample, obtained chiefly from wells, a tank, and a magnificent "aqueduct." But cesspools exist, the town is undrained, and its epidemic liability is very high. In 1883 the total registered deaths were 295, of which 71 were due to cholera as already stated, 86 to small-pox, 45 to fevers, and 37 to bowel complaints.

There is no question, in a case such as this, about the effect of bad water; nobody denies the injurious influence of polluted water on health. The danger does not, however, lie wholly in this direction, but, on the assumption that impure water is somehow a specific cause of cholera (or as some assert the sole cause of cholera), which, if acted on in the present case, would leave Eroda just as it is, and its people liable to cholera and other epidemics.

34. In the same district is *Karur*, a town of 9,205 inhabitants, which had a total death-rate of 51·6 per 1,000, half of which, or 25·2 per 1,000, was due to cholera. The cholera deaths in this small town were 232 in number. Those from small-pox 16, from fevers 55, and from bowel complaints 53, making together 356 epidemic deaths out of a total mortality of 475. Now in this case the element of pure water was absent. It is obtained "from the river, public and private wells, and two irrigation "channels. Some of the private wells are situated close to the privies. No improvement appears to "have been made in the conditions of the two irrigation channels noted last year; they are in the "same insanitary condition, and subject to all kinds of pollution."

This might give weight on the side of the cholera water theory were it not for the Erode experience and for the presence of these other facts about Karur:—"Drainage unsatisfactory and defective. There "is no regular system. Only one masonry drain exists, with a cistern at either end, and the contents "of which are carted away and thrown on the river bank. These cisterns always overflow, and are "a great nuisance. Drainage of houses also is defective." Karur appears to require sanitary work of all kinds, and when cholera came round it easily found a locality.

35. Cholera was prevalent in *Coimbatore* district, within which these two towns are situated, and its cholera death-rate was 2·0 per 1,000. The corresponding rate, as we have seen for Eroda, was 7·1 per 1,000, and for Karur 25·2 per 1,000. The simple facts appear to carry with them their own practical lessons. Impurity of subsoil was present in both cases as the fundamental localizing condition of cholera, and in the Karur case the local evils appear to have been added to by bad water. Experience in England has been similar to that of India. To prevent cholera single remedies do not necessarily answer, but there appears to be a prime necessity for an all round improvement, such as a cleansed site, cleansed and ventilated tenements, personal care and cleanliness, protection from the weather, wholesome water, wholesome food. Bad water alone does not necessarily produce cholera, nor do sewers and drains prevent it, if the site remains impure, the tenements foul, overcrowded, and unventilated, and their surroundings filthy. Nothing short of general care and all round improvement, especially in cleanliness, can be relied upon permanently to reduce disease.

36. *Madura* is one of the most populous towns of the Presidency, and contains 73,807 inhabitants. This town possesses some epidemic interest, as one of the points from which the great cholera invasion that reached England in 1848 took its departure. Madura district, in which it is situated, yielded a cholera death-rate in 1883 of 2·0 per 1,000, or four times the previous five years' average. The town itself had a death-rate from cholera of 11·2 per 1,000, and a death-rate from all causes of 37·5 per 1,000. It has hitherto been deficient in all sanitary requirements for so large a population, and "the "river Virgai, the chief source of drinking water, as it enters the town receives the drainage of a "burial ground, and its bed is used as a latrine all the year round, and persons, cattle, and filthy "clothes are washed in it." To remedy this great evil trial wells have been dug at safe points in the dry bed of the river, underneath which is a large flowing water-current that can be safely made use of by suitable arrangements for raising and distributing the supply. Drainage is still in an unsatisfactory state, although considerable improvements have been made. "It will take some time "to work out a satisfactory system of drainage for so large a town as Madura, but it is fairly begun, "and, if prosecuted with the same energy, Madura, before many years, will be a well drained town." Conservancy appears to be attended to, but, as the town is to be supplied with water, care should be taken to combine the new drainage with the water-supply, otherwise the added water, if passed into the subsoil, may become an added disease cause.

37. *Salem.*—This town has a population of 50,667, and its sanitary history for the year presents some peculiarities which are worthy of being inquired into. For instance, the death-rate of Salem district in 1883 was only 16·7 per 1,000, and its previous five years' average was 14·9 per 1,000. The town rate for the same year was 21·3 per 1,000, and for the preceding five years it was 20·3 per 1,000. But when we come to analyse the rate we are met at once by facts which appear to throw doubts on the registration, or census, or both. Thus we find that the rate of 1883 for the town was made up of 7·5 per 1,000 from cholera, 1·9 per 1,000 from small-pox, 3·7 per 1,000 from fevers, and 1·6 per 1,000 from bowel complaints, and thus 14·7 per 1,000, or above two-thirds of the mortality, were due to epidemic diseases. In the absence of cholera the year's death-rate would have been 13·8 per 1,000, and as regards fever, this epidemic town, if its statistics were reliable,

would take rank among the most healthy of all sub-tropical towns. It would appear as if improvement in the registration were required, as well as more active efforts to improve the sanitary condition of the houses. The drainage "is defective both of streets and houses; cesspools abound. The water "from the wells is somewhat brackish," a not unusual concomitant of cesspits. The only satisfactory statement on these subjects is that "the construction of drains parallel to the river is under con- "sideration," as is also "the improvement of water-supply and the introduction of artesian wells."

*38. *Tinnevelly.*—Population, 23,221. The registered death-rate in 1883 was 33·8 per 1,000, and the previous five years' average 36·1 per 1,000. Its cholera death-rate was 10·9 per 1,000, while that of the district was 2·6 per 1,000. The water-supply of this town is received through channels "subject to all kinds of pollution." "The Sanitary Commissioner during his visit to the town of "October 1883 found the road round the Minakolam tank frightfully defiled with human ordure, "and saw a large number of women washing themselves and their clothes in the tank." Drains are without "any systematic construction, hence the drainage of houses and streets is unsatisfactory; "numerous cesspools exist. Tinnevelly has not improved, but retrograded as regards cleanliness "since last inspection." We have in this town an example of high epidemic mortality, with an exposition of its causes. It has a municipal government which appears to have arrived at these results of its work.

39. A somewhat similar account is given of *Trichinopoly*, which has a population of 84,449. Its death-rate is a little over 23 per 1,000 on an average. It was 23·6 per 1,000 in 1883, but if this estimate were correct, by deducting 5½ per 1,000 for the cholera of this year, we should have a remainder of 18·1 as the rate exclusive of cholera. There appears to be some error in the returns, especially as the figures by no means correspond to the sanitary facts stated in the Report. For example, it is stated, as regards the water-supply, that "with all the measures adopted to prevent the "sources from pollution, contamination does take place, and the water is defiled in many ways."

Next, as to drainage, it is stated that "there is no regular system. Only the main streets and "principal bazaars are provided with open drains, often choked with all sorts of rubbish. The "backyards of houses are kept very filthy. Numerous cesspools exist."

The plea of want of funds ought not to be accepted as an excuse for such a state of matters. A year's loss of health for so large a population would go far, if saved, to pay for the required work. Besides, what is the municipality there for, if not to provide funds and apply them intelligently to the prevention of epidemics?

40. These instances, taken from the municipal reports, will illustrate the influence up to this time of municipal action on public health questions. Good in certain directions has no doubt been done, and in the majority of reports there are no specific allegations of neglect such as those we have discussed, but surely some more efficient steps should be taken to improve the larger towns.

41. *Local fund circles.*—There are 30 of these circles, which, for practical purposes, may be said to include all the population of the Presidency except that part which inhabits the towns. Among the circle populations all the real sanitary problems may be said to lie, and yet it is in country districts that funds are smallest in amount and sanitary requirements are most urgent.

The total expenditure for the whole year 1882–83 was as follows:—

	Rs.
Conservancy	160,678
Improvement of village sites	24,950
Water-supply improvements	75,980
Fairs and festivals	7,843
Other sanitary objects	45,414
Markets, &c.	34,656
Total	Rs. 349,521

Not much could have been accomplished with so limited an expenditure, and nevertheless the whole grant for sanitary purposes was not expended.

42. On this, the most important of sanitary questions, we can only repeat what we have often stated, that the epidemic susceptibility of Indian populations is due to the insanitary condition in which village populations live. Without going into details, which we have fully discussed in our suggestions, we may sum up the case in the following words.

Daily cleansing and keeping clean is the only method by which village subsoils can be kept from being used up. Neglect of cleanliness in times past appears to have led to the pollution of village sites and the sources of village water-supply. These unhealthy villages cannot be removed to new ground, and all that can be done is to stop the sources of further subsoil pollution, by observing strict cleanliness, and by simple surface drainage, filling up holes, and the like. If this be done, time will cleanse the subsoil, and the liability to epidemics will decrease, but in the meantime the unwholesome water-supply ought to be remedied. Of course these great improvements would require time if considered as a whole, but this difficulty would cease if each village were separately dealt with, for the whole matter is in reality a single village problem, and there are village officers in existence whose services might be called upon to solve it.

43. The Sanitary Commissioner reports that there is increased activity visible on the part of town municipalities, and this, so far, is satisfactory. We are also disposed to concur in the view that there

is a certain amount of progress manifested by the reports, and also by the mortality statistics. The jail experience is very hopeful, as showing that efficient improvements in the public health are as possible in Madras Presidency as elsewhere, and we must leave the matter in the hands of the Government, to take such steps as may be practicable to remedy the acknowledged evils.

44. We may state, in conclusion, with reference to the degree of importance in the water question which the Sanitary Commissioner appears to attach to the supposed "cholera bacillus," that no sufficient proof has been adduced to show that this microphyte is peculiar to cholera or to water consumed by persons living in cholera localities, or that it is the cause of cholera; while, even if the assertions were accepted as true, this would lead to no modification in the sanitary improvements required for cholera localities, simply because the bacillus itself requires certain conditions for its cultivation, and these are the same as exist in the impure water of affected localities. It follows that, even if the bacillus were proved to merit all the importance which has been claimed for it, it could not be dealt with otherwise than as an additional proof of the necessity for local sanitary measures, which moreover, is obvious enough already.

24th July 1885.

No. 3.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner of the Government of Bombay for 1883.

In our Memorandum on the Report of the Sanitary Commissioner for 1882 we gave the population and other details for each district in the Presidency. It is not necessary to repeat them in the present memorandum, and we shall deal with the returns as a whole.

1. According to the census of 1881 the population of Bombay Presidency, with the military included, was,—

Males	8,497,718
Females	7,956,696
Total	16,454,14

The average population per square mile for the entire area was 132·85. But the population density differed greatly in different districts. The most sparsely peopled area was Thar and Parkar, which had about 16 inhabitants per square mile, and the most densely peopled district was Kaira, which had 500 to the square mile.

2. The births among the population in 1883 were, of—

Males	261,966
Females	239,835
Total	501,301

= 30·50 per 1,000. The previous ten years' average birth-rate had been 21·35 per 1,000, and all that can be said about the figures is that the registration is improving, and that the rate for 1883 is nearer the truth than the rates of previous years. The lowest birth-rate of 1883, namely, 15·92 per 1,000, was registered in Hyderabad, and the highest, 44·09 per 1,000, in Dharwar. The district tables appear to show that registration of births is better done in some districts than in others.

The subject of birth registration is fully discussed in the Report, but the general results are all that we need notice.

3. The deaths in 1883 were as follows:—

Males	221,110
Females	199,088
Total	420,198

= 25·53 per 1,000 of the population.

The annual registered deaths since the famine years 1877–78 have been:—

Years.	Deaths.
1879	337,542
1880	328,673
1881	381,450
1882	343,418
1883	420,198

These annual figures appear to show that death registration is better carried out as a whole than the registration of births, although the district returns yield evidence that the work is better done in some areas than in others. Thus in 1883 Upper Sind frontier district yielded a death-rate of 9·19

per 1,000, which may be left aside. But we have for Hyderabad and Karachi death-rates of 14·47 and 14·98 per 1,000 at one extremity of the scale, and Khandesh at the other with a death-rate of 41·97 per 1,000. Discrepancies such as these can only be equalized by greater care in record.

4. The following per-centages of deaths at different ages may be here introduced, because they are arrived at from deaths actually registered :—

Ages.	Per-centage of Total Deaths.
Under 1 year	21·35
1 and under 5	19·19
5 „ 10	5·90
10 „ 15	3·46
15 „ 20	3·84
20 „ 30	9·98
30 „ 40	9·52
40 „ 50	8·20
50 „ 60	8·18
60 and upwards	10·38
Total	100·00

It appears from this abstract that 40·54 per cent. of the total deaths in 1883 took place at ages under five, a fact which by itself is an index to the defective sanitary state of the people.

5. *Causes of mortality in* 1883.—The next abstract gives the causes of mortality for a period of 11 years :—

Death Causes.	1883.		Mean of 10 Years, 1873 to 1882.	
	Number of Deaths.	Ratio per 1,000 of Population.	Number of Deaths.	Ratio per 1,000 of Population.
Cholera	87,954	2·31	21,621	1·33
Small-pox	13,404	·81	6,522	·40
Fevers	266,741	16·21	255,531	15·70
Bowel complaints	35,292	2·14	33,150	2·04
Injuries	5,978	·35	6,440	·40
All other causes	60,829	3·70	68,270	4·19
All causes	420,198	25·53	391,534	24·06

This table shows that the deaths from all causes registered in 1883 exceeded those of the previous 10 years' average by 28,664, equal to a ratio of 1·47 per 1,000 in excess, and when we analyse the causes it becomes at once evident that the excess is due solely to the greater prevalence of epidemics in 1883, during which year the deaths from cholera exceeded those of the 10 years' average by 16,333, the small-pox deaths by 6,882, the deaths from fever by 11,210, and those from bowel complaints by 2,142 deaths. The excess of epidemic deaths in 1883 over the average was thus 36,567, while the excess from all causes in 1883 over the previous 10 years' average was 28,664. The difference between the two sums represents 7,093 fewer deaths from accidents and all other causes registered in 1883 than in the previous 10 years' average.

The practical conclusion, therefore, is that there was a great augmentation in epidemic susceptibility among the people in 1883, a sure proof that sanitary work has not yet reached its causes, and pointing at the same time clearly to the sanitary measures required, and the urgent necessity of taking them in hand without delay.

6. We have already seen that the district which yielded the highest death-rate of the year was Khandesh. The rate was 41·97 per 1,000, and we shall select this case as an illustration of how, in such cases, the death-rate is composed, and how, when sanitary work has not been done to diminish the epidemic susceptibility of the people, enormous losses of life may come very suddenly.

The population of Khandesh in 1881 was 1,287,231. Its mean death-rate for 10 years had been 22·48 per 1,000, and in 1882 the rate was nearly the same, 22·97. In 1883 it was nearly doubled, a result due to the causes which follow. Its average loss from cholera during 10 years had been 1,747 deaths, or 1·63 per 1,000 of the population. In 1882 there were only 135 deaths from this disease, or 0·11 per 1,000. During January, February, March, and April 1883 there was no forewarning of the coming epidemic, which suddenly swooped down on the people in May and carried off 882 of them; in June there were 2,824 deaths; in July 5,214; in August 2,420, when the epidemic suddenly disappeared, there having been only 71 deaths in September, and three in November. All the 26 registration circles were affected, and 764 villages out of 2,660 furnished the deaths, which, from first to last, numbered 10,914, or 8·82 per 1,000 of the population. We are now in a position to state that, although we know not what epidemic cholera is, we do know that it manifests its presence locally, and that by changing the character of the locality it ceases to do so. If these 764 unfortunate villages had been dealt with on the same principles as have been applied elsewhere in India, we should have had every reason to have anticipated that much life would have

been saved. The excess of the cholera death-rate in 1883 over the previous 10 years' average was 7·19 per 1,000, so that without this epidemic outburst the total death-rate of the year would have been 34·78 per 1,000.

7. But cholera was not the only epidemic from which the excess of mortality took place. The 10 years' average small-pox deaths were 860, or in the ratio of 0·83 per 1,000. In 1883 these deaths were 2,345, or 1·90 per 1,000. Again, the annual fever deaths which yielded a 10 years' average of 16,945, or 15·82 per 1,000, was represented in 1883 by 30,569, deaths, or 24·71 per 1,000. Lastly, the bowel complaint deaths, which on a 10 years' average gave a ratio 3·15, rose in 1883 to 5·14 per 1,000.

These epidemic diseases, taken together, gave rise to an epidemic death-rate in 1883 of no less than 19·11 per 1,000 in excess of the previous 10 years' average, and now we have the great general death-rate of Khandesh fully accounted for. Without the excess of epidemic mortality the death-rate of this district for 1883 would have been, not 41·97 but 22·86 per 1,000. Before our practical knowledge of sanitary work and its results became what it now is, the reply on the whole case, would possibly have been that this great mortality was simply due to epidemics. No such reply is now possible. The severity of epidemics is determined by the nature and extent of insanitary conditions, and if there be executive sanitary authorities to deal with these conditions, epidemic death-rates mark the extent to which these authorities have discharged or not discharged their duties.

8. We shall next give some account of the epidemics of the year in the Presidency, beginning with *cholera*.

The five northern districts of Bombay Presidency, including Sind, escaped cholera altogether in 1883. They were out of range of the epidemic. Of the western districts, Ahmedabad, Broach, Panch Mahals, and Kaira suffered comparatively little, as did also Dharwar, Kanara, and Ratnagiri.

The real epidemic covered the central and eastern districts of the Presidency, and the monthly mortality returns show that the outburst of cholera in Bombay Presidency followed the same time law as the epidemic outbreaks in the Central Provinces and the Berars. The whole constituted in fact, a single epidemic area, within which cholera was almost absent until April and May; and during the subsequent months cholera gave rise to great mortality, until near the end of 1883, when it subsided over the whole affected provinces. Many hundreds of square miles were attacked simultaneously in all the provinces, and in all of them it ceased at the same time. In 1883 they formed one distinct continuous epidemic area.

In other memoranda we have given brief abstracts of cholera history for the Central Provinces and the Berars, but it was necessary to show the relation of the facts to those which presented themselves at the same time in Bombay.

9. The year's mortality from cholera in Bombay was made up of 34,919 deaths in the country districts and 3,935 in the 62 towns, in all 37,954, giving a death-rate of 2·37 per 1,000 for the districts, and 1·87 for the towns. The rate for the whole population, affected and unaffected, was 2·31 per 1,000, but the cholera death-rates varied from zero up to 9·81 per 1,000, the highest rate of the year, in Ahmednagar district. There are 285 registration circles in Bombay Presidency, in 174 of which deaths were registered. But the outbreaks were purely local, and were confined to 3,200 villages out of 24,431. Likewise, out of 62 towns 43 had deaths and 19 escaped.

10. The monthly prevalence of the epidemic was as follows:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	28	July	12,708
February	1	August	6,783
March	18	September	1,230
April	936	October	895
May	5,622	November	340
June	9,447	December	146

The statistics present no evidence of spreading from a centre or centres.

The epidemic in its action resembled that of an intervening force, falling on detached population groups, and leaving the other groups free for the time at least.

11. The next abstract shows the annual cholera mortality in the Presidency for a period of 18 years.

Years.	Cholera Deaths.	Years.	Cholera Deaths.
1866	23,027	1875	47,555
1867	5,143	1876	32,117
1868	6,841	1877	57,252
1869	52,330	1878	46,743
1870	2,666	1879	6,937
1871	5,231	1880	564
1872	15,642	1881	16,694
1873	283	1882	7,904
1874	37	1883	37,954

The famine and scarcity years 1877–78 show the highest death-rates, otherwise the data show a two years' period of lower mortality followed by periods of augmentation. As a simple matter of fact, and without any theory, there is an appearance as if time were an important element in the question of predisposition when the epidemic period comes round. It is very much to be regretted that, even allowing for the great epidemic mortality of the famine years, this abstract shows no indication of falling off in the liability to cholera. The conclusion of course is that, whatever sanitary work may have been done in the villages, it has not yet reached the causes of epidemic localization. There are circles which show death-rates of 3 per cent. from cholera alone, and all that can be said is that there must be removable causes for fatality such as this.

12. Some interesting facts are stated about the town of Nasik, where there were 428 deaths from cholera, or 17·76 per 1,000 of the population. The town contains 3,745 houses, of which 546 or 14·58 per cent. were invaded, besides temples, mosques, &c. The Assistant Sanitary Commissioner states that the per-centages of attacked floors in these 546 houses stood as follows, ground floors 48·93, one storey 46·78, two stories 3·97, three stories 0·33, and he concludes from the figures that "the "nearer the ground or the lower in every respect the type of house, and of perhaps its inhabitants, "the greater its susceptibility to cholera." He further describes the attacked places as follows:— "I have seen buffaloes, cows, ponies, and goats housed round the chowk (open space in centre of "house), sharing such quarters with lodgers or servants. Its faulty drain is apt to and sometimes "does become choked, and then a nuisance arising from the combined accumulation of animal "excreta and house filthy water is very objectionable. In a certain chowkless cholera-smitten house "the ground floor was occupied by cattle, and more resembled the interior of a neglected pig-stye "than a place of human abode. Overhead cholera appeared."

In another like instance a buffalo and a cholera patient were lying side by side in the same compartment on the basement.

Other similar details regarding cholera affected houses are given, and they can only lead to expressions of regret that in a town under any form of municipal government such neglect of the true interests of the people should be possible.

The remedies proposed by the Assistant Sanitary Commissioner and sustained by Mr. Hewlett are, "a new water-supply, improved drainage, and a better system of practical sanitation throughout the "town." The Assistant Sanitary Commissioner states the two following cases as facts. While cholera was very severe in a particular section of Nasik, the water for which was taken from the Godaveri opposite the Kekti gate, the place of supply was shifted higher up the river, and "a decline "in the number of attacks on that area was at once most marked." The other fact relates to an outbreak of cholera amongst poultry venders encamped in diminutive grass huts, which "completely "disappeared on the removal of their abodes *en masse* some 200 yards in a south-west direction in "the very teeth of the monsoon." This was simply an experiment on the influence of unclean locality on cholera, which took itself away, or rather was left behind when the subjects, the people, were removed out of it.

13. Besides these specific cases the Report contains full statistical details for each district, but there is nothing in them which calls for special remark on sanitary grounds, except that the whole history is one of localized cholera attacks, the general causes of which are quite well known, while so far as concerns the village populations, there is no evidence that their high susceptibility to epidemics has been in any way diminished.

Mr. Hewlett has done his part in preparing instructions at the desire of the Government for the guidance of villagers with reference to outbreaks of cholera. But we must again repeat what we have often insisted on, namely, that an attacked village is already a cholera locality, with which little can be done except to leave it, and that the lesson furnished by all experience is that, when an epidemic disease breaks out among a group of people, the mischief arising from previous neglect has been completed, and that the time for effective work has passed away. In Mr. Hewlett's own words, "The people, at times when there is no cholera, should be warned that the surest preventive of "cholera is to have clean air, clean food, clean water, clean houses, and clean persons." But the "missing link" in this procedure is the want of some person or persons to see that the work is continuously carried on.

14. *Small-pox and vaccination.*—The following table shows the annual deaths from small-pox during the last 12 years:—

Years.	Deaths from Small-pox.	Years.	Deaths from Small-pox.
1872 - -	26,599	1878 - -	4,475
1873 - -	9,935	1879 - -	1,156
1874 - -	3,903	1880 - -	940
1875 - -	3,461	1881 - -	539
1876 - -	11,817	1882 - -	1,630
1877 - -	27,369	1883 - -	13,404
Total six years	83,184	Total six years	22,144

This table shows two important results in the past history of small-pox in Bombay. First, the disease is liable to epidemic increase and expansion. Second, the history in the second column varies greatly from that in the first, for it shows that, while the epidemic character is maintained, there has

been a great reduction in the mortality. We shall presently see what relation this lower death-rate bears to vaccination.

15. Small-pox deaths were returned from all the districts, with two exceptions, Shikarpur and Upper Sind Frontier. The total country deaths were 9,731, or 0·68 per 1,000. Of the 82 towns 49 were attacked, and yielded 3,673 deaths, or 1·74 per 1,000. The rate for the province was 0·81 per 1,000. Out of 285 registration circles 212 registered deaths; but out of 24,431 villages only 2,577 returned small-pox deaths.

16. The monthly incidence of the disease is shown in the following table:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	1,039	July	616
February	1,947	August	460
March	2,814	September	328
April	2,228	October	302
May	1,296	November	446
June	830	December	1,033

Of these deaths 4,544 took place in children under one year of age. Above one and under 12 there were 6,960 deaths, and 1,900 above 12 years.

17. The vaccination staff for the official year 1883–84 was as follows:—

Deputy Sanitary Commissioners	5
Superintendents of Vaccination	3
Inspectors of Sanitation and Vaccination	31
Assistant Superintendents	5
Clerks and karkuns	29
Vaccinators	464
Peons	489
Total staff	1,023

The vaccinations performed by this staff for the whole Presidency in the same official year 1883–84 amounted to 883,839. Of these 826,965 were primary vaccinations, and 56,874 were re-vaccinations. The successful primary operations were 791,323, or 95·69 per cent. of the whole. Of the re-vaccinations 37,657, or 66·21 per cent., were successful.

18. The relation of these results of vaccination to small-pox mortality might be estimated from the following data, if all the births were registered:—

Births returned	501,801
Died under 1 year	89,708
Considered available for vaccination	412,093

But as some of these deaths may have taken place from small-pox, we should be perhaps nearer the truth in assuming the whole number, or say half a million, as the available supply of children.

We have now to compare with this the aggregate successful vaccinations, which for ages under one year amounted to 307,358, or three fifths of the births. Again, the vaccinations between one and six years of age were 178,627.

We have already seen that one of 13,464 deaths from small-pox in 1883 the deaths under one year of age were 4,544, or a third of the whole year's loss, and it appears to follow as a practical conclusion that greater effort should be made to extend vaccination at ages under one year, for by doing so the absolute protection will be greater. But the last six years' mortality in the table given above shows distinctly that for some reason or other the deaths from small-pox have undergone a very notable reduction, and as the only apparent cause is the cumulative effect of vaccination at the rate of three-quarters of a million of operations a year, we are apparently justified in congratulating the vaccination department on this result of its work.

19. *Fevers.*—The following abstract gives the registered deaths from fevers during the last 12 years:—

Years.	Deaths from Fever.	Years.	Deaths from Fever.
1872	206,747	1878	357,876
1873	183,201	1879	286,526
1874	283,717	1880	246,779
1875	279,156	1881	272,493
1876	220,933	1882	245,156
1877	336,865	1883	266,741
Total six years	1,355,519	Total six years	1,673,279

If the fever diagnosis on which this table rests were reliable, we should have to admit a large increase of fever deaths of late years, but from what we know on this subject all that can be admitted is simply the fact that a larger number of deaths under this head have been registered.

20. Fever deaths were registered in all the districts and in all the towns. The fever death-rate for the former was 16·76 per 1,000, and for the latter 12·4 per 1,000. The rate for the whole Presidency was 16·21 per 1,000, and the previous five years' average was 17·26 per 1,000. All the 285 registration circles returned fever deaths, as did also 22,077 villages out of 24,431.

The highest fever-rate of the year, 24·71 per 1,000, was returned from Khandesh, and it is worthy of remark that the lowest rate of the year was returned from Bombay city, the dense population of which, amounting to 773,196, yielded a fever death-rate of 7·47 per 1,000.

21. The monthly fever mortality was as follows:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	23,513	July	23,176
February	21,114	August	23,703
March	22,869	September	20,755
April	22,385	October	19,144
May	20,512	November	23,787
June	20,700	December	25,153

22. There is an interesting fact stated about Sind which shows that epidemic death-rates taken over the whole population do not necessarily afford a correct idea of the facts. Deaths from all causes in Sind division were in the ratio of 15·16 per 1,000, suggestive of deficient registration, while the fever deaths in the same division amounted to an apparently low ratio of 11·42 per 1,000. But the Deputy Sanitary Commissioner calls attention to the real meaning of the figures, and it is this:—In 1883 there were 36,582 deaths from all causes in Sind, and of these no fewer than 31,558 were registered as fever deaths. The fact is not an insolated one, for in 1881 there were 27,575 fever deaths registered out of a total mortality of 31,914, and for 1882 the figures were 37,785 fever deaths out of a total of 42,337.

It appears that the tendency to death in Sind lies in the direction of fever, and it is accounted for as follows:—"The chief cause may no doubt be found in flooding the country by the river Indus. "The inundation of 1882 stands unrivalled. Vast tracts of land in certain districts were covered "four months with the water which overflowed from the canals. These districts became very "unhealthy, and severe fevers, resulting in a largely increased death-rate, followed." We have the means of checking this view of the case by comparison with the European troops for only two points in Sind, Hyderabad, and Kurrachee, but the numbers are scarcely large enough for the purpose. They are as follows,—Strength at two stations, 1,007. Deaths all causes in 1883 = 12, of which 3 or 25 per cent. only were due to fevers, instead of 86 per cent. as among the civil population. It may, however, be fairly inferred that a large proportion of the deaths in Sind is due to fevers. Formerly, we raised certain questions regarding the lower rates of the Indus delta, when compared with the rates in the delta of the Ganges. But the present data give a new aspect to the question. In 1883 the fever death-rate in Bengal was 13·81 per 1,000 for the delta regions; it is higher probably by three or four per 1,000, but the facts are not accurately known. Neither is the general death-rate known with much accuracy.

If we take the figures, however, as they present themselves, we are led to the conclusion that the population of Lower Bengal is a much less healthy population than that of the Indus valley, which moreover suffers very little from cholera while the Bengal population suffers much. But that, as regards fever, there is not that difference in favour of the Indus delta that was supposed. It is true that a weakly population has less power of resistance against malaria than a healthy one, but so far as malaria itself is concerned, it is no respecter of persons.

This is very old experience confirmed.

23. If the civil registration could be depended on to the same extent that the cantonment registration may be accepted, we should have a means of useful comparison between the two, affording results, certain of which would be satisfactory as showing improved cantonment sanitary condition, and some others the reverse.

An example or two will illustrate this point.

As already has been stated, Khandesh district had a reported fever-rate in 1883 of 24·71 per 1,000. Within this district is the cantonment of Nasirabad, whose fever death-rate in the same year was 28·60 per 1,000. The administrative sanitary question which these figures raise is obvious enough, and involves the sanitary improvement of the cantonment. The admission-rate among European troops in this cantonment was 1,941·3 per 1,000 from all causes, of which 1,042·4 were due to fevers. There was, however, only one death from remittent fever.

As an example on the opposite side we may take Poona, whose district death-rate from fevers was 16·08 per 1,000, while the cantonment rate was 7·50 per 1,000. From among European troops at this station there were 240·1 per 1,000 admissions from fever, and the deaths were two from enteric fever and two from remittent fever. The fever death-rate was 3·68 per 1,000. Data such as these are of much use in sanitary administration, because they show where money may be most usefully spent.

24. As regards the general fever death-rates given in Mr. Hewlett's report, it may be safely stated that their very amount shows that these rates are due to local rather than to general causes, and that the first and earliest remedies, which are also well known, ought to be applied in the villages.

25. *Bowel complaints.*—The mean deaths registered under this heading in 10 years have been 33,150 per annum. In 1883, the deaths were 35,292, and the monthly numbers registered were as follows :—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	2,406	July	4,149
February	2,100	August	4,450
March	2,211	September	3,374
April	2,403	October	2,891
May	2,683	November	2,790
June	2,990	December	2,845

There is nothing in the year's history of this disease class calling for remark.

26. *Injuries.*—The deaths from injuries in 1883 were 5,978, below the preceding six year's mean, which was 6,430. Of these deaths, 2,713 were by drowning, 130 by poisoning, 179 by hanging, 355 by wounds, 95 by wild beasts, and 1,215 by snake-bites. The death-rate from injuries averaged 0·36 per 1,000 for the Presidency.

During the past five years, 7,563 persons have been drowned in wells, a fact which, as Mr. Hewlett says, ought to suggest the question whether nothing can be done in the way of covering the wells to prevent this loss of life, and, at the same time to protect so many domestic water sources from pollution. The answer is, of course, at hand, and it is that, under a proper sanitary administration for villages, accidents or suicides in wells ought to be prevented.

27. Under the head of *All other causes* there were 60,829 deaths registered, in regard to which nothing is known.

28. *Sanitary works (military).*—The actual outlay on sanitary works (military) during 1883 was Rs. 174,733, and of this amount Rs. 95,855 were spent on new Native infantry lines at Jacobabad, leaving about 7,880*l.* for sanitary work at all other stations.

This small amount was no doubt usefully spent in details of improvements, especially in flooring, water-supply, and simple draining operations.

At Neemuch 12 wells had been domed over, and the executive engineer states that he thinks this plan of protecting wells a mistake, because "it prevents the wells being cleaned out, and does not "admit of deepening by the dredge, and renders blasting impossible," and it does not prevent the water from the persons of the bathers falling back into the well.

There are other and better ways of protecting wells whereby every one of these disadvantages can be avoided. We have shown one simple method of doing this in our suggestions. Although the available funds for barrack improvements have been very small, so far as can be judged of by the lists, the amount appears to have been expended usefully as regards the health of stations. But far greater improvements are needed at several of the stations where fever is prevalent.

29. *Sanitary works (civil).*—Under this head is stated the year's income and expenditure in 163 municipalities, having a conjoint population of 1,881,519 within which sanitary work was more or less done in 1883. The total income for all of them was Rs. 2,710,952, and of this amount the outlay for conservancy was Rs. 1,148,902, or not far from 50 per cent.

We have already mentioned Khandesh district with its high epidemic susceptibility. In this district there are 19 municipal towns with a population of 150,535, and these towns spent Rs. 24,845 on conservancy, or about a rupee per annum for every six people. Was it worth while to spend it?

Besides conservancy, much useful sanitary work is being done in these small towns in the direction of improving the water-supply and drainage, but cesspools are still the usual means of house drainage adopted, and so long as this is the case there can be no security during epidemic periods.

The following substitute for drainage exists in Hyderabad, "There are 61 iron tubs in the city for "the reception of foul water, and seven galvanized iron swing donkey carts are constantly employed "in removing the foul water from them." This is certainly better than allowing the water, after being fouled by use, to drain into the subsoil, but it would perhaps be useful to keep an account of the daily cost of this operation and of the quantities removed, and how the water is disposed of.

At Ahmedabad 133,000 gallons of water a day are raised by steam pumps from the river Sabarmati, but the spot selected for the waterworks is at the lowest point of the town, and after the river has been fouled by washing clothes, &c. In this case the proceedings appear to have got into a wrong groove at the beginning, for the water after being raised passes through a filtering tank and is distributed partly by earthen and partly by iron pipes, so that the authorities clearly intended to supply pure water. The subject is being reconsidered, but any way money will have to be spent in providing a purer intake, and this might have been avoided by very ordinary technical knowledge, had it been available before the scheme was decided on.

30. *Local fund circles.*—There is very little information as to the sanitary condition or improvements in these circles, which ought to include all the civil population outside the municipal towns. The chief works of the year were well improvements, useful, no doubt, in their degree, but forming only a very small item in rural sanitary work.

31. Perhaps the most important section of the present Report is that on the Sanitary Commissioner's "Personal proceedings and general remarks." The first part of the section is occupied by a discussion on the present condition of Bombay flats with reference to the filling up of the area by town sweepings. The area to be raised is about 1,500 acres in extent, and at the date of the Report 72 acres had been reclaimed, but under such conditions as to give rise to great nuisance, and in the opinion of the Sanitary Commissioner to endanger health when the nuisance is greatest, which happens to be the case in the rainy season. Hitherto the work appears to have been done on no organized system, and there have been other agencies besides the filling in, which have tended to increase the nuisance, such as partial fillings in by private parties so done as to interfere with the natural outfall of the drainage; raising ground for railways by deep trenching on each side the roadway, whereby the drainage water stagnates and causes nuisance besides obstructing drainage; permitting actual sewage to run on the area; permitting rice cultivation; the state of tanks, &c., on the area. Then as to the material used, which ought to be only clean selected street sweepings, with as little of putrescing material as possible; nevertheless the material was found to contain refuse of beef, mutton, fish, vegetable market *debris*, night-soil, and during the rains about 200 cartloads of cowdung are deposited daily.

It will be seen that this proceeding, which is intended, when complete, to effect an important sanitary improvement, has been conducted in defiance of sanitary rule. One interesting fact is mentioned, namely, that 31 years after a part had been filled with town sweepings, pieces of hay, straw, &c., were distinguishable 5½ feet below the surface. In giving any opinion on this long contested subject, all we can do is to restate the principles of procedure, which are as follows:—

The material used should be clean, and without putrescible organic matter, but it is doubtful if ordinary street sweepings can fulfil this condition. The area should be filled so as to advance equally along the same line, and to an equal level on a surface raised to the required height above datum; allowance being made for partial contraction and subsidences, exits should be provided for the displaced water. When an area is completed it should be at once placed under cultivation, but in such a locality wet culture is quite inadmissible. For this purpose the practice of covering the filled in area with earth should be continued. Nowhere, but more especially in such a climate, should there be any building of habitations on the reclaimed area. The best use to make of it would be to devote part to dry culture, and part to tree and shrub planting and garden ground. For a great city like Bombay, part of the area would make a splendid public park.

32. The drainage of Bombay is still in a most unsatisfactory state, after so many years of deliberation. The original intention was to remove house sewage by house connexions with the main drainage scheme to the sea at Warli. But the following passage from the Resolution of the Government shows the present position of the scheme:—"The municipality are as yet far from the "realization of this scheme. The system of sewers is in process of construction, but over a large "area it has not yet been commenced. No house connexions have been made. The fresh water-"supply is confessedly inadequate for the purposes of conservancy." This system also meets with opposition in certain quarters as being alien to the habits of the people, and nevertheless we have in the present Report the following statement on the subject by the Sanitary Commissioner, who says:—"I may mention, in connexion with this subject, that I inspected the water-closets which have "been erected as an experiment in the Native town, and I have come to the conclusion that, with "a plentiful supply of water, they are a success. They were free from smells, and the Natives "have found no difficulty in using them. Of course they require supervision, but their immense "superiority over the Native privy must be acknowledged by every impartial observer."

33. The estimated population of Bombay for 1883–84 was 807,905, and the chief sanitary problems which it presents are how to cleanse the houses and keep them clean, and how to supply the people with water for all purposes.

It is nearly a quarter of a century since the subject was first dealt with, and the present position is that the town and houses are still undrained, and there is not enough of water. Calcutta has all its sewage system complete, and it has got its water-supply, and there is no reason apparently why Bombay, which has nearly double its population, should have so long lagged behind.

In their Resolution referred to, the Government set forth the necessity of getting the cleansing done somehow, if not in one way yet in another. But considering the great importance of Bombay as a centre of commerce, and its ever present liability to epidemics and to quarantines consequent thereon, nobody would object if Government were to interfere and do the necessary work if the Municipal Commission is inclined to waste more time.

34. The accounts show that in 1883–84 the outlay for the health department, mainly required for removing house filth by hand labour and carts was 84,000*l*. Let the cost of house cleansing be separated and capitalized, and it will be seen how large a capital sum would be in hand for permanent work.

35. The practical result of Mr. Hewlett's inspection is stated as follows:—"The improvements in "the city of Bombay which have taken place during the last 10 years have been many. Perhaps "no greater has been effected than the raising of the ground level in Khetvadi by filling it in. On "all sides I see places which I remember to have been sources of disease gradually being improved,

" but the town is still an Augean stable, and requires an immense deal to be done before it can be " considered as at all approaching a satisfactory condition. One of the greatest wants from a sanitary " point of view, after an additional water supply and the completion of the sewage scheme, is, in my " opinion, a Building Act."

This discussion properly belongs to our Memorandum on the Bombay Municipal Report, but the questions have a practical bearing on the proceedings of other municipalities in the province. After completing his inspection of the city, the Sanitary Commissioner visited other places, and he gives a list of these, with the following remark:—"It seems to me that, as a rule, in the smaller munici- " palities, the Commissioners do not consider it to be any part of their duty to make any inspections " whatever into the sanitary conditions of the towns they live in, and they almost invariably delegate " this important duty to the Municipal Secretary, who has, generally speaking, had no sanitary " education at all, and who trusts a great deal too much to the Muccadam."

Even under so imperfect an administrative system some work, no doubt, is done, but a better organization of the whole town sanitary service is obviously required.

36. That good can be effected in this direction is shown by the fact that there are cases in which good work has been done by Municipal Commissioners, and there is, moreover, a very remarkable sanitary report on the condition of the city of Ahmedabad, drawn up by Mr. Ranchodlál Chotálál, Chairman of the Municipal Commissioners, in consequence of the Government having sent him our Suggestions and Memoranda, in which we raised certain questions as to the high death-rate of the city and its causes.

The report is a model of its kind, and we must hope that it may serve as such for other municipalities. Referring to fevers, we had asked how it happened that the fever death-rate of Ahmedabad was 35·65 per 1,000, while that of Bombay was 8·29 per 1,000, and here is the Chairman's reply:—

" We have no system of drainage at all. Our rain-water finds its way towards the river by natural " water-courses, and for the house sewage water some of the houses have got cesspits, called khalcooas, " attached to them. These pits are dug close to the house, to the depth of 15 or 20 feet, and are so " constructed as to allow all the sewage water thrown therein to be absorbed through the bottom and " sides in the surrounding subsoil, and thus, where the cesspits are arched over to the depth of 5 feet " from the surface ground, the surface is apparently clean and free from any bad smell. The subsoil " of Ahmedabad being porous, the khalcooas water easily finds its way to the water-bearing stratum, " which is within a few feet of the bottom of the khalcooas. This khalcooa system fouls the water of " all the wells in the city, and makes it unfit for drinking purposes. It, however, keeps the surface " clean, although the subsoil is far from being wholesome." Again,—"There are thousands of houses " in the city where no provision of any kind is made for the removal of house sewage. They have no " cesspits of any kind, and the people residing in such houses must throw the house sewage in front " of their houses, to allow it to be soaked in by the ground, and as many houses are situated in narrow " lanes not exceeding 5 or 6 feet in width, and as the houses are high, the sun's rays would not reach " the soaking ground for more than an hour or two in the daytime. It is therefore easy to imagine " that great dampness and malaria must prevail in such locality. . . . We see everywhere on the walls " of all houses in the city for a few feet from the ground marks of decay in the bricks and chunam or " clay, as remarked at page 5 of the 'Suggestions.' This mark on the walls is called *loona* by the " Natives, and is the evident proof of the unwholesome state of the subsoil" (it is the leprosy of the house of the Jewish sanitary law).

Questions relating to the water-supply, over-crowding, drainage works, &c., are dealt with in the same enlightened manner, but the great interest of this report is in the additional light it throws on fever causes in Indian towns, and Mr. Ranchodlál Chotálál has rendered a great service to sanitary improvement by preparing it. We must hope that its statements may receive the most earnest attention of the municipality. Ahmedabad contains 124,767 inhabitants. Its average five years' death-rate had been 57·53 per 1,000, and 40·80 per 1,000 in 1883, and it had a fever death-rate of 24·25 per 1,000.

The foul soakage of the subsoil, the closely built unventilated town area, by which damp malarious air is diffused through the houses, and the rise of subsoil damp in the walls, which tends to convert dwelling rooms built above the ground level into cellars built below it, are the fever causes revealed in this Report. It is for the municipality to decide whether these grave defects of locality can be most effectually and economically dealt with by a general system of drainage, or by some other simpler method. Any way the subsoil must be dried, and an arrest put on the upward rising of foul damp into the house walls.

We are glad to learn that one of the Native Municipal Commissioners of Poona was preparing a vernacular pamphlet to spread information on these important matters among his countrymen.

37. The following facts have an important bearing on the subject of ground damp in relation to the health of troops. Mr. Hewlett states that after the infantry barracks of Ahmednagar had been vacated for 24 days, and no water had been used, he had the stone flooring taken up and a hole dug down to the depth of 4 feet, and that all the earth under the flooring was damp and foul smelling. The flooring had been laid on rubble masonry, which was also very damp and signs of dampness were found in the barrack room walls. Five out of the twelve barracks showed damp walls. The wash-houses adjoined the barracks, and it seems probable that water may have entered the subsoil in this way. He advises separate washhouses, and cementing or asphalting the floors. But besides this measure, it would be safe to raise the flooring so that an open air space might be left under the floor and the above asphalte. We fear that many other barracks in India would be found to present similar unwholesome conditions, the result simply of bad design and construction, and we have in these and

similar facts a sufficient explanation of the prevalence of fever. On a former occasion, similar defects in the position and drainage of wooden huts in the Crimea were to a large extent remedied and fever arrested by cutting away the ground so as to completely isolate the huts from surrounding subsoil by means of deep trenches, and by providing ventilation under the plank flooring where such existed. India barracks of this kind are merely a worse kind of wooden hut.

38. As this matter is of great importance in fever etiology in India, we desire to call special attention to the following facts, which show not only the presence of the fever cause, but its effects. In 1877 the Bishop of Bombay was attacked by remittent fever while residing in a house in Poona. He had to be removed to Bombay, where he recovered after a protracted illness. Shortly after the Bishop left the house some ladies attached to the mission came to live in it, and one of them occupied the same room, and her bed was placed on the same spot as that on which the Bishop's bed had stood. She was attacked and died of enteric fever. The Medical Officer could find nothing about the premises to account for the fever, but at last he had the floor taken up. The ground below was found to be very damp, and on digging down "the smell was so bad that he had to run away." This fever was clearly due to subsoil damp and filth, and the agency of a specific germ was quite unnecessary, while the observed cause leads directly to the remedy. The origin of the damp in this case was supposed to be the draining of bath-room water into the subsoil, through a rat hole, but our contention from the very beginning has been that barracks for European troops should be so constructed as to render such accidents impossible, and this view will have to be adopted in the end. It would be a useful proceeding to take up the flooring of every room in which a case of enteric fever has taken place, and while raising the floor to renew the ground below it.

There is a discussion in the Report on an old subject, the mussack, and the filth it communicates to the water. The only remark which appears to be called for on the subject is, that admitting the convenience of the mussack on the march, we are living at the latter end of the 19th century, at a time when the mechanical arts might possibly be able to provide a perfectly wholesome substitute for this very antiquated water reservoir, and one a very great deal more convenient.

40. We now come to that part of the Report which, considering the magnitude of the interests involved, is the most important, viz., the sanitation of villages, of which there are 24,431 in the province, each one of which may at any time become the centre of an outburst of epidemic disease. As regards one disease, Mr. Hewlett says, "The one great cause of fever throughout India is the "existence of dampness in an impure and foul surface and subsoil in inhabited areas." There are, as he points out, certain general malarial conditions common to the country, but the cause of fatal fevers are local, just as in the case of a cholera epidemic, which covers large areas, and yet selects its victims according to strictly local conditions. In the case of fever, the local causes are foul damp, and in the case of cholera they may all be included under one word, "filth," and the removal of these conditions may be said to include the whole village sanitary problem. Impure water has to be set aside, and good water provided, but this need is simply one of the results of subsoil fouled by the habits of the people.

Lately much stress has been laid on the fact that the evils can only be removed by education, which is partly correct, but, while generations are being so far improved as to see the need of attending to their health, the people, as Mr. Hewlett points out, are dying, and the working power of those who survive is much damaged, and the country impoverished. A mere statement of the case ought to carry its own remedy with it. That the work can be done is shown by the following examples. Dr. Chaucer, Deputy Sanitary Commissioner of the Southern Deccan Registration District, says in regard even to Native States:—"In some villages of the Native States in this district very strict orders "and regulations have been made. Prickly pear is cut down, and areas marked out for natural "purposes;" and Mr. Hewlett continues: "I, too, was much struck on my late tour with the very marked "difference between the sanitary condition of villages in British and those in Native territory. It "was remarked to me, 'Oh, in Native States we have a great deal more "hookum," much less law, "and no Accountant-General.' Allowing that this is so, still I cannot help thinking that these "measures, which are absolutely essential for the public health, can and ought to be carried out in "villages in British territory as well as in Native States." Of course they could, and the work ought to be done more effectually, but the facts simply show the want of a sanitary executive, after above 20 years of discussions and reporting. Were it necessary, additional arguments could easily be drawn from this Report to enforce this conclusion. But, in fact, the entire past history of Indian epidemics and of Indian villages shows—

1. That their sanitary state, and the local epidemic causes, have been long made out.
2. That the successive sanitary officers of the Presidency have done their utmost to bring the facts to the knowledge of Government.
3. That the villages are much in the same state as they were, and hence that epidemics of cholera and fever, with their following poverty may be expected to recur as heretofore.
4. That the time has arrived for converting all this knowledge to practical purposes, even if only a few villages were selected to begin with.

The sum and substance of this Report, as of others which have preceded it, is that an executive sanitary authority is urgently required to improve the health and working power of the Bombay Presidency.

6th August 1885.

No. 4.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for Bengal for 1883.

1. The population element of the vital statistics of 1883 in the present Report is that of the census of 1881, namely, 66,163,884.

In previous Memoranda we have shown how this population was distributed over the districts of Bengal in connection with the two most important elements, the births and deaths in each district. It is therefore unnecessary to repeat the data for the present year, especially as the registration is still so imperfect that no reliable estimate can as yet be formed of the year's ratios either of births or deaths in any registration district. All that can be said is, that in some districts the work is better done that in others, and what the ratios really show is not the true sanitary condition of the people so much as the greater or less imperfection of the registration itself.

2. Properly speaking, there is no general birth registration, on account, apparently, of the difficulty attending it. Births are registered in 46 municipal towns only. These towns had a population in 1881 of 1,685,159, and there were registered in them the births of 19,872 males and 17,343 females, together 37,215, equal to a total birth-rate of 22·08 per 1,000 for the year 1883, a ratio palpably below the truth. Some town circles registered fewer than 10 per 1,000 births, the higher rates were between 20 and 30 per 1,000. In a few cases the ratios exceeded 30 per 1,000. The highest rate of the year, an exceptional one, was returned from Jamalpore, namely, 49·17 per 1,000. Many of the town circles have populations too small to afford reliable results, and the ratio of 22·08 for the whole of them may be taken as representing the work done in this branch of vital statistics, and it fell short of the death registration by no less than 7·87 per 1,000, so that, apparently, a third more people died in the towns than there were children born to replace them.

3. Registration of deaths is conducted in some way or other in 648 circles, included in 45 districts, and the returns for 1883 showed that 676,175 deaths of males and 569,501 of females had been registered, 1,245,676 in all, showing a registered death-rate of 18·82 per 1,000, about 2 per 1,000 above the previous five years' rate, which was 16·75 per 1,000. These ratios are probably not much more than half of the true rates. District death-rates vary even more than do town birth-rates. The lowest death-rate of the year, 9·93 per 1,000, was returned by Monghyr district, which has a population of nearly two millions; the highest rate, 36·07 per 1,000, was registered in Nuddea, where the people have been suffering from fever. As a whole, however, there is less difficulty in death than in birth registration, but neither branch can be said to be in a satisfactory condition. The reasons of this circumstance are well known to the authorities, and strenuous efforts are being made to secure greater accuracy in the returns, but it is not possible as yet to adopt the local registration machinery whereby the work is more successfully done in this country. If there has been no increase of accuracy in the Bengal registration, there has been increase of area and population under the registration, such as it is.

4. *Causes of death.*—The following deaths were registered under the usual heads in 1883:—

Diseases.	Total Deaths.	Death-rates per 1,000 of Population.
Cholera	90,439	1·36
Small-pox	9,714	·14
Fevers	913,766	13·81
Bowel complaints	55,270	·83
Injuries	23,670	·35
All other causes	152,817	2·30
All causes	1,245,676	18·82

Divided between the town population of 2,469,163 and the country population of 63,694,721, the death-rates were as follow:—

Diseases.	Ratios per 1,000.	
	Towns.	Country.
Cholera	3·64	1·27
Small-pox	·27	·14
Fevers	13·77	13·81
Bowel complaints	3·54	·73
Injuries	·40	·35
All other causes	5·64	2·28
All causes	27·28	18·49

It will be observed that under all the heads except "fevers" the country registration is far more deficient than that of the towns. For reasons often stated, the fever registration is untrustworthy Cholera deaths are better reported, and their rate was nearly threefold greater in the towns than in the country circles. The country registration of "bowel complaints" and "all other causes" shows in what particulars this branch of the service was most defective in 1883.

5. We shall next give a brief sketch of the year's epidemic history, beginning with cholera, in regard to which we shall quote Dr. Lidderdale's opening statement:—"The disease was present in all "the 648 registering circles in the province, excepting 46, prevailing epidemically in only 47, against "115 in 1882; severely in 64, against 118; and mildly in 491, against 376; and it attacked only "6·55 per cent. of the villages, against 10·98 per cent. The casualties amounted to 90,439, and the "death-rate to 1·36 per 1,000 of population. The reduction on the figures of 1882 being 91,913 "deaths, or at 1·39 per 1,000, and on the average of the lustrum 1878–82, 16,107 deaths, or at "·25 per 1,000." Cholera deaths were reported from 16,416 villages out of 248,751 in the province.

Cholera was thus present over the entire area of the province in low intensity, shading away to nothing over a few areas, with increase in others, but only reaching 4 per 1,000, or a little over this, in two districts out of 45, the important fact being that whereas in 1882 there were 182,352 deaths, the loss of life in 1883 amounted to less than one-half of this number.

6. We shall next compare the monthly incidence of cholera during the two years with the rainfall of 1883.

Months.	Cholera Deaths.		Rainfall, 1883.
	1882.	1883.	
			Inches.
January	8,947	10,675	·69
February	7,588	4,702	·46
March	15,892	6,777	1·51
April	25,587	11,021	2·40
May	27,544	13,187	4·65
June	29,858	11,369	13·60
July	18,125	8,935	14·30
August	12,912	6,994	12·04
September	5,064	2,613	6·72
October	6,756	2,289	·29
November	12,357	3,725	·12
December	16,714	3,432	1·36

* This abstract gives the cholera history of Bengal for 24 months, and as will be seen this period includes three great epidemic outbursts of the disease, the first between March and August 1882, the second between November 1882 and January 1883, and the third from April to August 1883. The same months also include four periods of decline. These facts belong to a series which might be extended backwards as far as the statistics reach, and they afford conclusive evidence that besides any constant causes which may exist over these cholera areas there is some other cause altogether which increases enormously in activity during certain months, and declines in activity in others. There is one variable cause shown in the table, the rainfall, which has had a very considerable influence on the mortality of both years, for it will be observed that, as usually happens, the dry months are attended and followed by increase of cholera, which declines after heavy rains. This influence is visible in the statistics of both years, but it would in no way account for the double mortality of the cholera months of 1882 over the same months of 1883. It need scarcely be said that no known facts about cholera microbes, contagion, or any other such assumed causes, could account for them.

7. The sanitary fact shown by the table is, that heavy rain, which cleanses surfaces, flushes watercourses, and cleanses and replenishes the water of tanks and wells, reduces greatly the local liability to cholera. And we know that similar results follow from artificial operations of cleansing and water-supply during epidemics.

8. As illustrations of this rule, we may cite the comparative exemption of fairs at which sanitary precautions were adopted. No doubt the epidemic was not severe, and the question of intensity has always to be taken into account, alike in places where there was little cholera, and in places where it showed itself in severity in estimating the influence of sanitary precautions on mortality. Take, for example, the Gunga Sagor fair held in 24-Pergunnahs in January 1883. This fair lasted a week, and was visited by 98,500 people, among whom there were 34 cholera cases and 7 deaths, notwithstanding the adoption of "all needful sanitary arrangements." Did these measures then fail of effect? Such, apparently, would be the question to which, if other facts were ignored, an affirmative reply might be given, but it may be here stated, once for all, that no single observation such as this can determine the question. While the fair authorities are adopting their local measures and registering the results, cholera is following its own course, and this is being mapped out by the statistician, and the present Report enables us to complete our information, which makes a very material change in the reply to our question, for we find that in this same month of January there were in the 24-Pergunnahs, including the suburbs of Calcutta, 1,745 deaths from cholera, or nearly a fiftieth part of the whole mortality of the province. There were, in fact, only three districts out of the whole 45

with higher death-rates. This fact, of course, is a measure of local epidemic intensity, which, as we have often urged, must always be taken into account in deciding such questions, although the fact itself must necessarily be unknown in most cases until the epidemic statistical history has been worked out. Half facts of this class are the real sources of most of the disputes which have taken place about the manner of cholera movement in time and space.

9. There is a case of alleged importation into Thana Soori of a different character which the Medical Officer appears to have taken pains to follow out, but there is the same difficulty in accepting his conclusion, which would logically be village quarantines, in a country where the statistics show a very general prevalence of cholera. Soori is in Birbhum district of Burdwan division in the Ganges delta, not far from Calcutta. The whole area is a well-known epidemic region, and the seven districts, including Howrah, yielded more or less cholera mortality during every month of the year. The cholera deaths, excluding those in Howrah, amounted to 1,352, or 1·33 per 1,000 of the population, while the deaths in Howrah amounted to 1,909, or 3 per 1,000 of the population.

Birbhum district, where the importation case is alleged to have taken place, had no cholera deaths in January and September 1883. It had in all 297 cholera deaths in the other 10 months, or ·37 per 1,000. It was in the month of October, when cholera was absent from Soori thana, that cholera was supposed to have been imported from Burdwan district, where, be it remarked, there had only been eight deaths, during the same month of September, and 43 in October. The following is the history:—"A zemindar of Nagoree (in Thana Soori, population 705) in October, went on a visit "to a friend in Panagore, in the Burdwan district, and stayed with him for three days. In the "house, unknown to him, there had been two or three days previously some deaths from cholera. "On the third day of his visit he was taken ill with purging, and straightway returned home, where "the disease developed itself, and he died next day at his own residence. Three members of his "house got cholera in succession, after two or three days interval of each, and all but one "succumbed."

From this house it is supposed to have spread simply by communication to the adjacent village, and was carried elsewhere. An obvious defect in this statement is the absence of dates, which are of essential importance in such inquiries; and, besides these defects, there is another case which may show that there was some other reason for the alleged facts besides simple importation, but in this case also there is absence of dates. All we know is, that in the course of the year there were six deaths in Soori town. Among these were the deaths of the police magistrate and his two sons. They were in the habit of taking long rides in the sun, and drinking large quantities of iced buttermilk on their return. The house well was bad. All three were seized with cholera, and died within 24 hours after attack. Here there could have been no question of importation, and, quite apart from any such question, there was cause sufficient for the fatal results, in a district where the statistical history showed the presence of epidemic cholera at the time.

10. In this brief notice of these cases, we have had no desire to decide the questions at issue either one way or another. All such questions have two sides, the scientific and the practical. In sanitary work, the first is only of use in so far as it leads us to practical results, and, as these must lead to outlay of public or private funds, we are bound to challenge the evidence and to reject opinion, for it is certain that there have been statements put forth on matters of opinion in some reports the only logical issue of which would be the entire suspension of all human intercourse between affected and unaffected countries.

11. It is more satisfactory to refer to really practical statements as to the presence of very notable local causes connected with cholera outbreaks, because these, if turned to practical account, for all depends on their being so made use of, will help to save life. Thus, it is said of Burdwan population groups that "good drinking water is not available in many places, the majority of tanks which "abound in the district being in an extremely filthy state." In some towns in this district the death-rate was between 2 and 4 per 1,000, increased apparently in Ranegunge town by concourse of pilgrims to 6·76 per 1,000.

12. Sonamukhi town, in Bankura district, had a cholera death-rate of 5·70 per 1,000. The place is densely populated and filthy, "with numerous foul tanks and cesspools, and the magistrate says "that, until this state of matters is remedied, this tract will continue to be visited by the disease in a "virulent form." The magistrate did what he could in this case to protect the water sources from impurity, and in another similar case the same steps were taken, and the population suffered little from cholera.

13. In Midnapore district, villages which suffered severely "are particularly filthy, very densely "populated, and in great need of sanitary arrangements." In the littoral tract of this district, the magistrate states that there is almost everywhere a great want of good drinking water. Two thanas in this district, largely inhabited by Santhals, "who are far more particular than any other Natives "about the water they drink," suffered least from cholera.

14. An instance is given in Hughli district, where cholera broke out in a coolie depôt "without "latrines or sanitary arrangements of any kind." There were 17 deaths, and the disease ceased as soon as the unaffected coolies deserted the place.

15. In two villages within Calcutta municipality, "coolies congregate for employment during the "jute season, and there being no houses available, they put up rough temporary huts, in which they "live crowded together without any regard to sanitation."

These people generally yield the first cases of the disease.

16. Another outbreak took place at Kanchrapara among coolies proceeding to Assam, and among the railway workmen there, as well as in surrounding villages. "The affected localities were stated "to be extremely filthy, defecation being carried on anywhere and everywhere, and the water-"supply from tanks and railway cuttings very bad."

Discussions about importation of cholera in the case of another population group in certain villages opposite Chinsura were very properly dealt with by the municipality sending people to clear the jungle and drains, and serving notices for tank cleansing and removal of filth.

17. Cholera appeared in the Darjiling tea gardens, some of it at 7,000 feet above the sea. The Medical Officer states that "in all cases that came under his personal observation, the disease "appeared to break out in places where some local insanitary condition existed, such as accumula-"tion of filth, overcrowding, contaminated water-supply,"—such examples are cited,—"but in no "case did he notice a tendency of the disease to spread to other persons than those living under the "peculiar conditions which seemed favourable to the development of cholera." But in this case, as in others, there was the usual apparent anomaly of bad localities escaping.

18. The following examples in Dacca are cited by Dr. Crombie to show that something more than importation of cholera infection is requisite for its propagation:—"A severe outbreak of the disease "occurred at Keranigunge, on the opposite side of the river from Dacca. At this outbreak it was "observed that, although there is the freest communication between this place and Dacca town, "ferry boats conveying clerks and others constantly plying between the two places, Dacca was "comparatively freer from the disease." A similar fact is stated regarding Naraingunge, the great jute centre of Eastern Bengal, which had 29 cholera cases only, although in direct communication with severely affected places.

19. Another illustration may be cited from Gya district, because the various elements bearing on questions of cholera outbreak are considered. In Aurangabad thana the cholera death-rate was 7·22 per 1,000. The disease began in Aurangabad subdivision, and extended to others in the vicinity. "The Civil Surgeon visited many of the affected localities, but could obtain nothing but negative "evidence as to the causation of the disease. In no instance, however, was it to be traced to "importation. It appeared to him that the disease spread, irrespective of lines of traffic, and that "the prevailing winds did not influence its course; but that rather, while during the earlier part of "the outbreak, the prevailing wind was west, the progress of the epidemic was from east to west. "Mr. Skrine, the magistrate, is inclined to believe that the progress and virulence of the disease was "fostered by the filthy habits and overcrowding of the population."

20. Two towns in Gya district, Gya and Daudnagar, yielded very high death-rates; the former, 8·85 per 1,000, and the latter 23·20 per 1,000, the greatest death-rate of the year. It is very probable, as the magistrate states, that inattention to sanitary measures was an aggravating cause of this outbreak.

21. Poori town, the great pilgrim centre, had only 169 cholera deaths, or 6·95 per 1,000. Poori district had a cholera death-rate of 1·26 per 1,000, against a previous five years' average of 3·97 per 1,000, a fact which shows that cholera intensity is due to some other element besides the pilgrim element, and this experience is not without interest in connection with diminished cholera mortality, in cases such as Cuttack, for example, in which the lower mortality of 1883 over that of 1882 is attributed to obliging pilgrims to pass the town by a road two miles away. It is reasonable to believe that prevention of overcrowding and filth by this measure may have lessened the amount of cholera, only the whole history should be allowed for at the same time.

22. The practical result of the cholera experience in Bengal during 1883 confirms that of all previous years. We know nothing of the real disease cause. This varies in intensity, so far as can be estimated by the death-rates in different years and in different localities, and the conditions which appear to affect the local mortality most markedly are those which may all be classed under the head of defective sanitation, such as filth, bad water, crowding of dwellings and villages permanently and temporarily by influx of pilgrims or other passengers, and these causes of augmented local mortality point to the required remedies.

23. *Small-pox.*—Deaths from small-pox amounted to 9,714, equal to a death-rate of ·14, or half the mortality of the previous five years, which averaged ·29 per 1,000. The town mortality was ·27 per 1,000. Small-pox deaths were returned from all the 45 districts, with the single exception of Bogra, showing the very general prevalence of the disease; but, as usually happens, there were large areas in each district exempt. This is shown by the fact that only 364 circles of registration out of 648 returned deaths, while the total year's mortality was reported from 4,323 villages, and 244,428 villages had no small-pox deaths. The deaths per attacked village averaged a little over two.

24. The monthly mortality was as follows:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	844	July	729
February	1,280	August	454
March	1,560	September	243
April	1,478	October	161
May	1,348	November	218
June	906	December	498

The highest death-rate of the year, 94 per 1,000, was returned from Poori, which usually yields the highest rate.

It is worthy of notice that out of the total small-pox mortality of 1883, amounting to 9,714 deaths, 1,883 took place in children under one year of age, and above half the deaths were returned in children under 12 years.

25. *Vaccination.*—The vaccination staff of the year was constituted as follows:—

Superintendents	8
Deputy Superintendents	11
Native ditto	5
Inspectors	67
Head vaccinators	24
Vaccinators of Circles	268
Ditto, municipal and dispensary	224
Apprentices	57
Licensed vaccinators	952
Total staff	1,616

The total vaccination work of the year was represented by 1,361,332 operations, of which 1,350,519 were primary, and the remainder secondary. Of the primary operations, 98·66 per cent. were returned as successful, and of the secondary operations 49·42 per cent.

Successful vaccinations, according to age, were as follows:—

Under one year	178,487
One year and under six	877,338
Above six years	269,028
Total successful	1,324,853

26. The most important element in vaccination statistics, so far as concerns saving of life, is the age at which the operation is performed, and it cannot be said that the results for 1883 are altogether satisfactory.

Thus the births, estimated at 30 per 1,000 of the population, ought to have amounted to 1,446,805, while the actual number of operations performed under one year of age was only 178,560, leaving 1,144,153 unprotected (exclusive of 126,092 infants who died under one year).

Vaccination as a current protection against the ravages of small-pox ought to save lives in proportion to the numbers of successful results in the first year of age, and it would apparently follow, from the year's facts that most benefit to the State would be realized by directing the vaccination work so as to reach an annually increasing number of infants. At present the figures show that practically these special subjects of small-pox are left very inefficiently protected.

27. The average cost of each successful case of vaccination was 1 a. 7 p., and the total year's cost of the service was 13,127*l.*

The vaccination report contains ample information on the details of the year's work, but these are departmental, and do not call for remark. There appears to be a general state of apathy on the subject among the people, who afford very little voluntary help to the service.

28. In the present condition of the statistics, it is not possible to estimate the results to the public health. No doubt lives are saved, but the fact is obvious enough, that the most susceptible subjects, the infants, require to be more efficiently dealt with, before much impression can be made on this disease. With these cautions we shall give the following figures from the Report:—

Areas.	Population.	Small-pox Deaths per 1,000.
Thoroughly protected	26,155,179	·07
Fairly well protected	14,424,427	·17
Very partially and unprotected	25,987,792	·25

29. *Fevers.*—We have already given the fever mortality of 1883. There were registered more or less incorrectly under this head 913,766 deaths, or a death-rate of 18·81 per 1,000 of the population, fever deaths were returned in all the 648 circles of registration into which Bengal is divided. No doubt the diseases classed as fevers were universally prevalent, but fatal cases were returned from 42,731 villages out of a total number of 248,571. The fever death-rates varied greatly in different districts. The greatest rate of the year was 30·12 in Rajshahye, while in Orissa division the rates were from 5 to 7·85 per 1,000. In Burdwan district, formerly the seat of a very fatal fever epidemic, the death-rate was 23·35, or a little under the preceding five years' average. Burdwan division as a whole yielded a fever-rate of 14·34 per 1,000, a little over the previous five years' average, and the general average of the country for 1883. Nuddea yielded a death-rate of 27·60, against a five years' average of 30·20. This district, its fever mortality and sanitary condition, were reported on by a special commission, the result of whose work we noticed in last year's Memorandum on Bengal.

We have often discussed the causes and remedies for these Bengal fevers, but the subject is of such great importance to public interests that we shall continue the discussion by abstracting the facts on the subject in the Report under review.

30. The following table shows the relation of Bengal fevers to rainfall generally :—

Month.	Average Fever Deaths 1878 to 1882.	Fever Deaths, 1883.	Rainfall in 1883.
			Inches.
January	71,597	83,949	·69
February	55,921	65,425	·46
March	58,049	64,785	1·51
April	58,574	68,439	2·40
May	53,906	59,243	4·65
June	49,575	54,541	13·60
July	52,521	61,552	14·30
August	59,349	70,597	12·04
September	62,216	77,233	6·73
October	75,808	85,673	·99
November	93,156	108,885	·12
December	94,449	113,449	1·36

Generally, but subject to local exceptions, increase of rain influences the amount of fever only to a limited degree. The great increase takes place after decline in rainfall and the setting in of evaporation with lower and more variable temperatures. It is the same law which prevails all over India, and its results to health can only be dealt with by removing those conditions through which the rainfall acts. We shall next give an abstract of the local reports which define these conditions. The evidence is, of course, not new, but it is necessary to restate it year after year to avoid the danger which is so apt to arise from taking the facts as matters of course, whereas the entire Bengal problem is involved in translating these facts and their results in practical measures for protecting the people from epidemics and their consequences.

31. The Native Civil Surgeon of Bankura appears to have imported the doctrine of a fever germ and suitable soil into the question of fever causation, but it is only an inference drawn from certain facts, and the practical result is what the germ hypothesis always logically leads to, namely, that only the nidus can be dealt with and not the germ, and he concludes, "Where the moisture in the "soil owing to the proximity of a marsh, is perennially damp, there the fever prevails the most." A list of six thanas and towns in Bankura is given in which the fever death-rates vary from 19·75 to 27·86 per 1,000, and Dr. Ghose tells us as a matter of observation that the death-rates are proportioned to the dampness of subsoil.

32. In *Birbhum*, where the fever death-rates lie between 20·10 and 26·92, the Civil Surgeon says, "that to the dryness of the soil the lesser prevalence of fever may be ascribed, while, on the other "hand, prolonged dampness and moisture bring about the opposite condition."

33. In *Serampore* subdivision, it has been observed that increase of rain is associated with increase of fever. This result is possibly due to local conditions, because it is an exception to the general law already mentioned.

34. *Nuddea.*—In our Memorandum on the Report of 1882, we discussed at length the fever of this district, together with its causes, and we shall merely abstract the following general data from the Report under review to continue the history :—

Years.	Fever Deaths per 1,000 of Population.	Percentages of Villages attacked.
1880	26·11	96
1881	35·54	94
1882	29·56	92
1883	27·60	96

These data appear to show that an endemic fever had taken on the character of an epidemic during the years 1881–82. This is not an unfrequent occurrence in fever districts, and usually attracts more attention than the current amount of disease is apt to do. But the only safe manner of considering the subject is to deal with the normal fever mortality and its causes, and if this be done we shall have a generally lower death-rate and fewer fever outbreaks. A contrary course of proceeding, including, as it necessarily does, relaxation of effort when the fever has ceased to take on the epidemic form, is sure to lead to loss of life.

35. In *Dinagepore* district the fever mortality was 17·17 per 1,000 in 1883, but the death-rates varied in different thanas between 20·40 per 1,000 in Patiram, and 71·94 per 1,000 in Dinagepore thana. It is clear that the latter of these thanas is a fever locality, and must be dealt with as such. We have specially adduced it, because of its possible relation to the results of the following

drainage work in Dinagepore town, which has a population of 12,560, of whom 215 died of fever in 1883.

The town was drained on the recommendation of a special committee of inquiry. The work was begun in 1879 and completed in 1881, but we can form no opinion as to its real character, and whether it was suited to its purpose, because no account of it is given. All we have to deal with are the following figures:—

Years.	Deaths per 1,000.	
	Fevers.	All Causes.
1874-78	12·44	25·56
1879	14·10	23·00
1880	14·71	21·70
1881	12·92	19·74
1882	13·69	19·98
1883	17·11	22·29

This abstract shows a general decline in the death-rate since the drainage work was taken in hand, with an increase in 1883, which was apparently due to the generally augmented fever mortality in that year. But besides the variable amount of fever which the table shows, there is no doubt of the striking difference between the fever mortality of the thana and that of the town. It is even possible that some of the town mortality may be due to the malarial condition of the thana. Any way there appears to be no sufficient reason for losing confidence in the drainage, and we are glad to see that further improvements in this direction are contemplated.

36. Rajshahye district had the largest district fever mortality of 1883. 91 per cent. of its villages suffered, and 30·12 per 1,000 of its inhabitants died of fever "chiefly of the intermittent type, "recurring frequently, and complicated with enlargement of the spleen and liver, anæmia and "malarial cachexia." One of the thanas, Putia, had a fever death-rate of 41·09 per 1,000, and the fever appears to be increasing in fatality. The cause of increase in 1883 is considered to have been bad water, caused by deficient rainfall. The magistrate states, "that many good tanks of former "years have been neglected, so that now most of the village tanks contain decomposed water. The "radical remedy is good tanks and wells, but these the people do not supply, owing to their "ignorance of the benefits of good water, and pretended poverty, nor will the zemindars render "assistance in this matter, although the cost of a good well is only five rupees, as they are fatalists, "and look upon the occurrence of sickness as calamities that human agency cannot control." We have here, in a few words, a prominent disease cause, its remedy, and how it could be done, but there is no moving power, and this the Government might supply with public advantage.

37. Rungpore district had a fever death-rate of 15·68 per 1,000, and the town of 19·06 per 1,000 Although the mortality was not so high as that of many other places, the magistrate says, "that "nearly every morning on arrival in Kutcherry he found a little pile of letters from the amlah "asking to be excused attendance on account of fever; that many had to go to their homes more or "less invalided, but he himself, who had never been ill for 20 years, had an attack; that up-country "men suffered particularly, being unable to shake off the disease like natives of the district; that "nearly all who had been in the service of Europeans had been laid up, and that of their number "some died." These facts resemble those formerly adduced regarding Burdwan, where, at times, prisoners had to bring home the police officers in charge of them.

38. Rungpore town is one of those in which drainage works have been carried out. But we have had no account of their nature. The drainage was begun in 1873 and completed in 1882, and the following have been the statistical results:—

Years.	Death-rates per 1,000.	
	Fevers.	All causes.
1873-77	19·95	36·88
1878	20·20	34·22
1879	13·06	24·82
1880	18·15	25·54
1881	19·21	26·50
1882	18·39	23·64
1883	19·96	29·57

"The scheme, however," says the Sanitary Commissioner, "is only a partial one, and does not "drain many extensive swamps to the east of the town, which undoubtedly exercise a prejudicial "effect on its health." He is nevertheless of the opinion that, so far as drainage has been carried out, "it has done its work." The town is not large, and contains 13,320 people. And, although the statistics show a large reduction in the general death-rate and in the death-rate from fevers, the magistrate's statement proves the extensive prevalence of fevers, possibly in less fatal forms; any way it cannot be said that the public health from this cause is satisfactory where the public service is interfered with in the way he describes. It is evident that this Rungpore fever is part of the general

fever of the district, aggravated possibly by town conditions of life, and that the remedy required is the extension of drainage works and the abolition of swamps. In estimating the results to health it should be stated that the more recent statistics include deaths which have been brought into account by progressive improvements in registration.

39. In Bogra district, certain thanas which suffered most severely from fevers are situated in localities where "rank vegetation and dense jungle abound, and the drainage is defective."

40. In certain thanas in Pubna district the fever rate was from 3 to 3½ per cent., connected apparently with local deficient rainfall, while "the reduction of temperature had, by inducing severe "complications in fever cases during the cold season given rise to high mortality."

41. In certain parts of Serajgunge town "the fever was of the remittent type, and prevailed in "April with great virulence and speedy fatality; the villages attacked are situated on low undrained "swampy land surrounded by dense clumps of bamboos, preventing perflation and sunlight, and "honeycombed with filthy excavations which receive night-soil, cow-dung, kitchen refuse, and house "drainage; and uncovered municipal trenches exist in close proximity to the town." The municipality should see to these disease causes being dealt with, and also whether the closing of a trench which admitted river water to the excavations had caused increase of fever. The real remedy, however, is filling up the excavations.

42. Fevers prevail with great severity in some parts of Dacca district, and the causes are stated as follows by the Civil Surgeon and magistrate. These are "the general tendency towards silting up of "the whole river system in the district owing to changes in the course taken by the bulk of the "Brahmaputra water, which, instead of passing as it formerly did through the extreme eastern "portion of the district into the Megna, now flows to the west of it, through the Jumna, into the "Pudma Ganges." This change is attended by the usual concurrents of failing streams and stagnation of subsoil water and fever.

43. In Faridpore district, but more especially in the Faridpore municipality, fever prevailed severely. "About four-fifths of the inhabitants had one or two attacks during the last quarter, many "had two or three relapses, and in a great number of the poorer classes enlargement of the spleen "and liver, jaundice, diarrhœa, and, in some cases, dropsy supervened." The fever death-rate was 29·23 per 1,000. The Civil Surgeon assigns this severe fever outbreak to the usual local insanitary conditions, want of conservancy arrangements, defective drainage, bad water-supply, jungle around houses, "interments within the compound of houses," crowding, and similar causes.

44. The chief fever causes in Backergunge district appear to be connected with defects in surface and drainage.

45. In Mymensing district "the localities near the Garrow hills and the Medhupore forest, where "jungle and rotting vegetation abound, and the condition of the tanks is bad, again suffered severely "from fever." River changes have also added to the prevalence of fever.

46. In Tipperah the fever death-rates were lower than in other districts taken as a whole. The higher side of the district suffered least, and "the most unhealthy parts are those towards the west, "where the general level of the land slopes towards the river Megna, which, with its numerous "tributaries, keeps the soil waterlogged and the subsoil waterlevel close to the surface."

47. In Mozufferpore district increase of fever in certain areas is ascribed to atmospheric causes.

48. In Durbungha fever is attributed to the generally low level of the country, and to the yearly occurrence of inundations, leaving large marshy tracts which never dry up.

49. In Sarum district fever is attributed by the Civil Surgeon to irrigation, and the greater difficulty experienced in draining the country owing to the railway now forming a bund across it. The fever mortality in this district is, however, not high.

50. The Civil Surgeon of Maldah gives the following account of the fever causes in this district:— "Groups of people congregated thickly together in villages surrounded by soil sodden and saturated "by the excremental discharges of years, little or no ventilation, air poisoned by the miasmatic "exhalations of decaying animal and vegetable *débris*, and water rendered impure by nature and art "are all quite sufficient to account for the spread, if not for the origin, of disease in an Indian "village."

51. It will be gathered from these facts regarding local fever causes in 1883, that these causes have been the same as those which have always acted. The primary causes of increase and diminution of fever are atmospheric, and atmospheric causes are beyond human control. But of equal importance are terrestrial agencies connected with the hydrography of the country, and these can be dealt with only to a limited extent. The courses of great rivers cannot be altered, but any local drainage defects attributable to the irregular action of rivers may be more or less remediable. But the main causes of fever prevalence which may be fairly laid to atmospherical and topographical conditions are not the main causes of fever mortality. These, as has been clearly shown in the present, as in previous Bengal Reports, are purely local. They are connected with the drainage defects and marshy conditions of defined areas which surround towns and villages. These admit of more or less remedy by suitable drainage works, or by belts of trees where drainage could not be carried out. But the main causes of fever mortality are to be sought in towns and village houses, and what the nature of these death causes is has been long known, and is fully given in the cases we have abstracted from the present Report. In choosing which of all removable causes we ought to begin with, there cannot be a doubt that the sanitary condition of houses and house compounds, including water-supply, should be at once taken in hand. This implies cleansing and keeping clean all houses and compounds,

protecting water-sources or providing new and wholesome supplies, town and village drainage by simple methods for removing surface water, filling up excavations, regulating the surfaces for surface drainage, none of them very difficult processes, should be at once taken in hand, and then the drainage of surrounding marshy areas. It should be kept in view, as an axiom in sanitary work in India, that disease causes are chiefly to be found in the dwelling itself and its immediate surroundings.

52. *Bowel complaints.*—The statistics of death causes registered under this head present the usual anomalies. Returns of such deaths were made by all the registration circles, with 20 exceptions only, showing how widespread were the diseases (chiefly diarrhœa and dysentery) which gave rise to them, but, nevertheless, the whole year's mortality was reported from no more than 23,120 villages out of 248,751, facts which appear to justify the views of the Sanitary Commissioner, that bowel complaint deaths have been enormously under-registered. Taking the facts as they stand, for there appears to be no reason to suppose that errors of this kind are greater in one month than in another, we may place side by side the mortality from these diseases with that from cholera already given, in order to see whether any relation can be traced between them :—

Months.	Total Deaths.	
	Cholera.	Bowel Complaints.
January	10,675	5,138
February	4,702	4,084
March	6,277	4,056
April	11,021	4,552
May	13,187	4,221
June	14,382	3,814
July	8,235	2,524
August	6,994	5,178
September	2,613	4,787
October	2,289	4,445
November	3,725	4,868
December	8,182	5,578

This comparison shows that there was no relation between the two classes of mortality in 1883, that cholera bears marks of much more accurate registration than bowel complaints, and were the data reliable they would show that the former disease was a true epidemic and not the latter.

53. The causes assigned for bowel complaint mortality are great alternations of temperature in July, August, and September, extreme cold night air and heavy dews of January, November, and December, acting on numbers of poor people insufficiently clad and poorly fed, who live in unwholesome localities and use bad water.

Bowel complaint mortality is hence set forth as an index to a generally defective sanitary state of the people, as distinguished from the action of purely epidemic causes, which is not far from the truth. The death-rates, however, vary greatly in town and country areas, to some extent due to the better registration in towns, but still the difference is too great to be attributable solely to this cause. The town-rate in 1883 was 3·54 per 1,000, and the country rate ·73 per 1,000.

54. *Injuries.*—Under this head were registered 23,670 deaths, or ·35 per 1,000 of the population, and of these deaths 10,071 were attributed to snake-bite and wild beasts, and 2,472 were suicides.

55. *Other diseases*, out of nomenclature, occasioned 152,817 deaths, or 2·30 per 1,000, or about a seventh part of the year's mortality.

56. *Port of Calcutta.*—We shall conclude this sketch of the year's sanitary history of Bengal by the chief facts relating to the floating population, which may be summarized as follows :—

The port was visited by 21,005 European seamen in 1883. When the census was taken in 1881 the numbers actually in port were 2,791, but this exceeded the estimate made by the Health Officer in 1883, which was 1860. The total cases and deaths which took place from among the year's visitors were as follows :—

Diseases.	Cases in Hospital.	Deaths.
Cholera	65	38
Diarrhœa	164	—
Dysentery	90	4
Fever, enteric	—	—
" malarious	323	4
" simple	114	—
Scurvy	14	—
Small-pox	3	—
Sunstroke, &c.	4	5
Other diseases	1,169	40
Total	1,948	91*

* Including 10 deaths out of hospital.

The death-rate from all causes among the year's visitants was 4·33 per 1,000, of which 1·76 per 1,000 was due to cholera. If the census population be adopted as an average, the death-rate for the year would be 32·60 per 1,000, and on the Health Officer's estimate it would be 48·92 per 1,000, and of this amount 20·42 would have been due to cholera. It seems probable that both ratios do not afford a correct estimate of the year's facts, at least in so far as any comparison can be made between them and the ratios for a fixed population. Probably the more correct account of the facts is the first one, which implies that out of so many visitants so many died.

If the population element could be relied on, the rates of successive years would be comparable, and the relative health expressed in figures, but in the present case we are informed that out of 65 cholera attacks 38 were ascertained to have taken place in new arrivals of less than a month. In this case sailors arriving from the open sea, at a port where there was cholera, paid the usual penalty of such arrivals. It will be observed that in the preceding table there is no entry of enteric fever, of which happily there was no case in 1883.

57. *Native port population.*—This was found by the census of 1881 to have been 25,409, and during the year there were 8,606 arrivals. There were 178 deaths, or 7 per 1,000. Of this number 116, or 4·56 per 1,000, were due to cholera. Both rates are unreliable, for it is not at all likely that there should be so great a reduction of mortality from that of Calcutta. The true reading of the figures would apparently be that out of such a number of people so many deaths had come under registration, and then the question would naturally arise, what had become of the others.

58. *Sanitary works, civil.*—Information under this head is given in abstracts which show the expenditure on sanitary works and measures in 177 municipalities and unions in Bengal in 1883. The total income, including the previous year's balances, for all these municipalities, amounted in round numbers to 332,876*l.*, and of this amount 34·48 per cent. was expended on sanitary works against 30·75 per cent. in 1882. The increase is partly due to removal of the police charges from localities doing sanitary work. Some towns spent little for sanitary purposes, but many others spent a large portion of their resources for this object. The year's expenditure may be classified as follows:—

	£
Conservancy and latrines	30,795
„ establishment	32,586
Drainage	9,606
Water-supply	16,044
Disposal of dead	762
Markets and slaughter-houses	1,653
Vaccination	1,099
Treatment of sick	16,933
Other works, sanitary	5,308
	£114,786

To this has to be added a sum of 60,616*l.* spent on construction, maintenance, and repair of roads all bearing more or less on sanitary objects.

59. *Drainage.*—The larger class of works of drainage or water-supply are under survey, consideration, or execution. To this class belong works of drainage for Serampore, Ghatal town in Midnapore, Berhampore, Lalbagh, Azimgunge, Dinagepore, Chittagong, English bazaar in Maldah and Cuttack. These works include drainage of areas also.

In Nuddea, where severe fevers were partly traced to drainage obstructions from public works, required waterways had been constructed or were under execution, and drainage outlets of considerable extent had been carried out in other parts of the district. It is too soon to look for results to health, and we do not know precisely the relation of the works to fever areas, but it may be stated that the Nuddea fever death-rate, which had been on a five years' average 30·20 per 1,000, was 27·60 per 1,000 in 1883. An important question regarding the Bengal and North-Western Railway was under consideration of the District Engineer in consequence of a report by the magistrate that unless sufficient waterway were provided the railway would back water a densely peopled district. This, of course, will be attended to.

The great swamp to the south of Rajmahal had been surveyed with a view to drainage of this fever source. Any drainage works in the towns will be chiefly by surface drains, but care should be taken not to make them of deep section. Shallow impervious surface drains are best.

60. *Water-supply.*—Under this head it is stated that the water-supply for Burdwan town had made much progress. Three settling tanks had been completed, a masonry clear water reservoir was under construction, pipes had been laid down in the streets, and filters were being formed. When this important work has been completed, and the people have access to pure water for domestic use, it will be of great public importance to watch the statistical results to health.

Burdwan town has a population of 34,080. Its five years' average death-rate had been 29·14 per 1,000, but in 1883 the rate had risen to 45·46 per 1,000, of which 3·55 were due to cholera, and 27·84 per 1,000 to fever. This is just one of the trial examples of unfrequent occurrence, from which important experience for future direction of local works may be obtained, because the the element of impure water will have been eliminated, and the result on the death and disease statistics ascertained. It would, however, be very advisable to complete the town drainage at the

same time, so as to remove the water, otherwise it is quite possible that the mortality may be apparently raised by an improvement which ought to have lowered it. A water-supply for Hughli was under discussion, and also for Howrah, but it had been doubted whether a good supply could be had from the river below Pulta. These projects are part of a more extensive one for supplying the riparian towns which suffer severely from cholera with water, and a wholesome source is indispensable. The matter was fully examined by the Army Sanitary Commission at the time the Calcutta water-supply was under discussion, and, in our view, no lower point of intake would be safe than the one from which the present Calcutta water is taken.

The proposed extension of the Calcutta supply to the suburbs to the ultimate extent of 4,000,000 gallons per diem had been decided on, and the requisite machinery was on its way from England. The water-supply of Berhampore had been improved by the formation of a river flushing channel to bring water for washing out and supplying tanks, &c.

Darjiling water-supply had been increased by appropriating three additional springs, laying down pipes, and erecting hydrants. Defects in the filtering arrangements at Dacca had been remedied. A project for supplying Bhagulpore town with filtered water had been submitted. In the English bazaar town in Maldah the water-sources were improved, but the municipality of Cuttack had negatived a proposal for obtaining a purer water-supply, leaving the people dependent on wells.

In Hughli district a water channel had been opened through the Kana Nuddi to bring water from the Damuda to the Saruswati river, by which a long series of stagnant pools had been turned into a flowing stream. This is a another of those test cases in which important experience might be obtained by collating the statistics for a series of years.

61. Some minor improvements are mentioned in bustees, which will, no doubt, be useful.

62. In the course of the year certain chapters and sections of various Bengal Municipal Acts were applied to a considerable number of towns and villages, referring to general sanitary regulation, lodging-houses, latrines, compulsory registration of births and deaths, and compulsory vaccinations, &c.

New Acts were also passed for the sanitation of Indian merchant shipping, the regulation of Native passenger ships, for amending the Poori Lodging House Act, and for revising the law relating to municipalities in Bengal.

63. On the subject of quarantine, it is stated that during the time quarantine was enforced against arrivals from Batavia and Sumatra, "no vessel from these ports was found to have had cholera on board." This merely repeats the almost universal experience of such proceedings. A matter of far more importance to the commerce of Cacultta was under consideration, namely, the extension of the Calcutta water-supply for Native passenger boats, which at present have to use river water.

Among proposed improvements in water-supply is the very advisable one of extending the Calcutta supply to Dum Dum, where the troops appear to have a very doubtful supply at present.

64. *Burial of the dead.*—This is a subject which has long been under discussion in India, and the time appears to have come when it should be taken into consideration with the view to some general legislative proceedings. The present practice is to bury the dead in houses or house compounds, or among the village houses, or to throw them into rivers.

The principles which ought to regulate the disposal of dead are perfectly well known, and only await application as far as possible, and in the interests of the public health, in conformity with Native feeling.

65. This section of the Report is concluded by a statement as to what constitutes "epidemic" cholera, made by the Calcutta Board to that of Egypt. We have already stated our views on this subject on other papers, and there is nothing to add to these.

66. Under the head of "*Personal proceedings*," a brief account is given of the manner in which shipping inspection is carried out. The Native Sanitary Inspector has the river divided into six districts, one of which he goes over daily in alternation, visiting the passenger and cargo boats and all descriptions of Native craft. He discovers and arranges for hospital treatment of sick, inspects the foreshore and conservancy, and reports foul cargo boats for cleansing. The following was the year's work:—

12,830 boats inspected, and 542 found filthy.
390 complaints made to the police.
327 persons found sick on board.
351 times latrines inspected, and 25 found filthy.
79 water boats inspected.

This Officer's work appears to have been well done for the Native craft.

67. The Health Officer himself inspected 815 inward and 649 outward bound vessels, and complaints were dealt with. The port inspecting work had been very efficient.

68. In the course of the year 3,866 villages were inspected by officers of the vaccination staff, and the abstracts of their work in the present report constitute not the least interesting parts of its contents.

These inspections covered a considerable area of country, and they reveal the same general neglect of cleanliness in houses and villages, the use of impure water, and, what perhaps is worse than all, an incurable apathy on sanitary questions of which epidemics of fever and cholera are the natural consequences.

One of the Deputy Sanitary Commissioners, Mr. Lyons, who appears to have been very earnest in the work, addressed the people in each village hát and bazaar visited, and pointed out defects and remedies, which were also brought to the notice of the magistrates. But he concludes that "sanitary "legislation of some sort to meet the requirements of rural dwellings is called for, if the physical "welfare of the people is espoused. My observations teach me that the people, rich and poor, educated "and uneducated alike, cannot or will not actively bestir themselves in bringing about sanitary "reforms."

Nevertheless, every one admitted their importance, but they objected to do what their neighbour would not or might not do. Even the village officers declined to act without a "perwanna" to enable them to enforce reforms. The obvious consequence of this state of matters is that the Government should step in and deal with these village sanitary problems. Something has been done for the towns, and, as we have seen, some improvements are being carried out there, but, as we have often urged, the town populations are a mere fraction of the whole population of Bengal, and it is hence in the villages that the causes of epidemics have to be encountered and overcome.

69. On the whole, the present year's Report shows advance in real sanitary work, although not by any means to such an extent as could have been desired. The registration of deaths is still very defective, and also the observation and record of facts about cholera by the local observers. But the main practical conclusion from the additional year's experience is that the remediable local causes which influence the mortality from epidemics are known; that the sanitary problems in Bengal are all included in the measures required for the mitigation or prevention of two epidemic diseases, fever and cholera; that these measures are known, and that which is really wanted is greatly increased activity in sanitary work in towns, and its extension to the vast village population, which numbered 63,694,721 in 1881, whilst the whole town population fell short of 2½ millions.

23rd March 1885.

No. 5.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for the Punjab for 1883.

1. In the opening section of the present Report, Surgeon-Major Bellew, the Sanitary Commissioner, has given a very interesting abstract of facts connected with the census of 1881, all bearing more or less on the sanitary condition of the people, and he has also included among them a detailed account of the manner in which the vital statistics of the province are at present recorded and collected. As this subject is intimately related to sanitary work, we shall state very briefly how the facts of births and deaths are obtained.

2. The village chaukidars are supplied with two registering books, one for births, the other for deaths, "in which the entries are made on the chaukidar's report by any resident of the village who "can write (usually the *bania*, or *patwari* or schoolmaster) and the lambardars of each village are "held responsible that these entries are made."

So much for the primary record, which, if strictly followed up, ought to yield a close approximation (except perhaps in the matter of diagnosis) to the numerical facts.

The chaukidars pay weekly visits to the police stations, bringing their books with them, "and "from these books and oral inquiries from the chaukidars the police registrars compile the fuller "registers which they maintain," and the police registrar signs the chaukidar's books in token of having seen it.

The duties of inspection of registers by Sanitary and Deputy Sanitary Commissioners by Sanitary Inspectors and Civil Surgeons are carried out according to rules, and methods are adopted for checking the entries.

There are, nevertheless, difficulties in the details, especially where facts have to be recalled from memory, which may introduce errors into the final results, but these are also being as far as possible guarded against, so that it must be acknowledged that very considerable advances have already been made in this province towards obtaining accurate records of these fundamental data of all sanitary work. While admitting the necessity of improvement in vital statistics, the Sanitary Commissioner, nevertheless, states that "the system of registration of births and deaths is as complete and as accurate as it can possibly be under present circumstances."

3. The system still admits of improvement, altogether apart from the question of diagnosis, but, such as it is, we must make the best of it, and, as we shall see, it affords suitable data for most sanitary purposes. But the figures alone would afford us scarcely sufficient data for our purpose, unless certain conditions brought to light in the census report quoted by Mr. Bellew be at the same time accounted with. These are stated as follow:—"Of the whole population, not less than 53·8 per "cent. depend primarily for their subsistence upon the produce of the soil, while a further 31·7 per "cent. earn a most precarious livelihood, and of these latter some two-thirds are dependent upon "the rural population. Thus failure of rain at once attacks the means of existence of some three "quarters of the population, while another tenth, dwellers in towns, suffer from the smallest rise in "the prices and are peculiarly liable to epidemic disease. Taking the population as a whole,

" the standard of living is exceedingly low. Add to this the universal ignorance of the most " elementary rules of sanitation." And then follows this statement in the census report showing the relation of these external conditions to epidemic visitations:—" The normal course of events " seems to be something of this sort. The rains fail and distress ensues. The next year the rain " fails again, and famine devastates the country, while immigrants pour in from even less favoured " tracts which surround us, and cast an additional burden upon resources already insufficient to " meet the needs of the resident population. The famine is followed by virulent epidemics of fever " and cholera; the old and young die literally like flies, while too many succumb even in the prime " of life; the death-rate amounts to an appalling figure, and births decrease in number. Favourable " seasons follow, the population, purged of its weak and sickly elements, exhibits a marvellous " recuperative faculty, and all prospers till the swing of the pendulum brings with it a return of " famine and pestilence." In proof of these periodical visitations of famine, the following data are introduced:—

Years.	Nature of Famine.	Interval in Years.
1783	Terrible.	
1802	Moderate	19=10×9
1812	Severe	10
1817	Slight	5
1824	Severe	7
1833	Terrible	9
1842	Slight	9
1851	Moderate	9
1860	Severe	9
1869	Terrible	9
1877	Moderate	8

4. We have thought it necessary to notice these statements chiefly because they attempt to trace the periodical epidemics of the Punjab to rainfall in its influence on crops. Famine, by itself, if we can judge from the Madras experience, kills off the population directly by destruction of the intestinal mucuous membrane and consequent famine diarrhœa, and fever. In so far as fever mortality is concerned, it augments this by increasing the predisposition of half-starved people to the action of ordinary atmospheric and local fever causes, but the causes must be present as an antecedent condition. There is no proof that famine causes cholera, but it may increase liability to attacks by lowered stamina and by necessitating the use of unwholesome articles of food. Epidemics of small-pox appear to be more directly influenced in their intensity by famine, but the general death-rate from all causes is, as might be expected, greatly raised during famine years, and for the months which follow. As a matter of fact, famine years do not necessarily yield the highest epidemic death-rates, except perhaps in the case of small-pox.

5. We have no vital statistics for the earlier famine years in the preceding table, but we can give the death-rates for the last years of the series, and also of the intervening years, which have stood as follows:—

Years, including two Famines.	Registered Deaths.		
	Cholera.	Fever.	Small-pox.
1869, terrible	9,258	272,946	58,195
1870	469	275,093	27,163
1871	369	213,548	25,584
1872	8,727	264,711	23,738
1873	148	219,909	25,699
1874	78	190,631	12,026
1875	6,246	279,825	13,594
1876	5,736	351,286	10,254
1877, moderate	29	219,281	12,296
1878	215	440,492	40,271

We should scarcely be justified from these data in concluding that scarcity of food was a direct cause of epidemic disease in the Punjab. Famine rather acts on the stamina of the people who are the subjects of epidemics, and these diseases being present a starved population will suffer more from first to last than a well fed and properly clothed and sheltered people. It is necessary to keep this distinction in view to avoid the error which might otherwise be introduced of mistaking a subsidiary predisposing disease cause, which can only be imperfectly dealt with for those primary predisposing causes which are all more or less within our control.

6. We shall next discuss the vital statistics of 1883.

The population element used in calculating the ratios is that of 1881, which consisted of—

Males	10,202,083
Females	8,640,181
Total	18,842,264

Of this population 17,512,378 inhabited the country districts, and 1,318,383 were returned from 49 towns.

7. The births registered during 1883 were of—

Males	393,321
Females	341,591
Total	734,912

equal to a birth-rate for the whole population of 39 per 1,000, and for every 100 females born there were 115·14 male births.

There were considerable variations in the number of births registered in different districts. The lowest registered rate of the year was that for Simla, which was 16·04 per 1,000 out of a population of 42,945, and the highest was 53·32 per 1,000, from among a population of 1,012,148 in Sialkote district.

8. The deaths registered were those of—

Males	256,348
Females	219,393
Total	475,741

equal to a death-rate of 25 per 1,000 against a previous five years' rate of 32 per 1,000.

We have already seen that for every 100 females born there were 115·14 male births, and the death statistics show that the balance between males and females was restored by the higher death-rate among males, of whom 116·84 per 1,000 died for every 100 females.

The lowest death-rate of the year was 16 per 1,000 in Peshawur division, the highest was 35 per 1,000 registered in Muzzaffargarh. The death-rate for the districts was 25 per 1,000 against a previous five years' average of 30 per 1,000, and the ratio for the towns was 30 against a previous five years' average of 47 per 1,000.

Taken as a whole, the numerical statistics show improving registration, and also better health, in 1883.

9. The following were the registered death-causes in 1883 (population 18,842,264):—

Diseases.	Deaths.	
	Total.	Ratios per 1,000.
Cholera	190	0·01
Small-pox	12,108	0·64
Fevers	306,185	16·25
Bowel complaints	14,607	0·77
Injuries	5,363	0·28
All other causes	137,298	7·29
All causes	475,741	25·24

The following were the corresponding data for hill sanitaria and cantonments:—

Population of 4 sanitaria	19,503
„ 33 cantonments	206,698

Diseases.	Deaths.	
	Sanitaria.	Cantonment.
Cholera	—	1
Small-pox	14	5
Fevers	190	1,369
Bowels complaints	53	128
Injuries	14	50
All other causes	164	1,098
Total	435	2,651
Ratios per 1,000	22	12

We shall next discuss the death-causes of the year.

10. *Cholera.*—It seems not at all unlikely that the single death-cause which was least fatal in 1883 was cholera. Were it not that the 190 deaths from this disease form part of the cholera history of the province they would scarcely require notice.

We have stated the deaths from cholera between 1869 and 1878 in a preceding table, and we may now add the deaths for the subsequent years, which were as follows:—

	Deaths from Cholera.
1879	26,135
1880	274
1881	5,207
1882	39
1883	190

Of the deaths in 1883 there took place 5 deaths, one in each of five towns out of 49 towns in the province, and the remaining 185 deaths were returned from 17 districts out of 32. But 10 of the affected districts returned no more than 1 death each. Three districts returned 2 deaths each, one 4 deaths, and another 5, but the real outbreak, so far as it was an outbreak, was confined to two districts, Delhi and Gurgaon, the former of which yielded 39 deaths and the latter 121; but none of the towns in either district suffered. Cholera deaths were returned from 32 circles of registration out of 446, and out of 34,973 villages no more than 52 were affected, and of these 5 were in Delhi district and 20 in Gurgaon. In the former district there are 743 villages, and in the latter 1,239.

The total death-rate in 1883 was just a thirty-sixth part of the preceding five years' average rate, which was 0·36 per 1,000 of the population.

11. The next abstract shows the monthly deaths.

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	—	July	31
February	—	August	41
March	—	September	5
April	7	October	—
May	53	November	2
June	51	December	—

12. We may here notice the earlier stages of this outbreak, because, probably from defective information, the idea of importation occurs in one of the reports, in which the facts are stated as follows for Delhi district:—"There was an outbreak of cholera at Majhesar, near Ballagarh, which "commenced about the 17th April, when one Nihala and his brother were seized, and about the "20th their mother and three other persons. Those cases were called 'fever' by the villagers, and "but an imperfect history of contagion could be elicited. However, on the 28th, several people "(about 80 in number) returned from a marriage at Alawalpur, in the Gurgaon district, bringing "back with them the corpse of one of their number who had died of cholera. This, apparently, lit "up the disease into an epidemic, 38 persons being attacked within a few days, out of which number "24 died. Among the subsequent proceedings taken in this case, quarantine was observed as far "as possible."

It will be observed that this case assumes the existence of cholera in Gurgaon, and its importation directly or indirectly into Delhi district from Gurgaon on or about the 27th or 28th April.

Let us next see what the Medical Officer of Gurgaon has to say on the subject. "The disease "was first reported to have occurred on the 11th of May 1883, in the village of Jodhariabas, situated "about seven miles from the town of Firozpur, at the foot of the hills towards the southern extremity "of the Firozpur tahsil."

Hence we learn from this statement that cholera first appeared in Gurgaon several weeks after it had broken out in Delhi district. Besides these facts, the cholera map shows that in April, when the Delhi outbreak took place, there were cholera deaths in other parts of the Punjab, and the dates in the Delhi report show that cholera had already shown itself in Delhi district a week before the corpse was brought home.

The history is so clearly an epidemic one that it would have been quite unnecessary to have noticed it, except for the contagion element in it; and we have noticed it simply to enforce the necessity for practical purposes of separating between facts and theories in all sanitary reports.

13. We are glad to find that in this case active measures were taken to improve the sanitary condition of the localities. The Native Assistant Surgeon, several vaccinators, and the police constables "had cleaned up the village, not omitting the wells, to a degree it had never before "experienced. Floors on which excreta had been passed were dug up, in spite of great opposition "on the part of the inhabitants; whitewash and disinfectants were freely used." The real mischief had, as usual, been done before these steps were taken, for the epidemic lasted till the 21st May. The facts have nothing to do with contagion or importation, but they point clearly to the necessity of improving the sanitary state of villages before, and not after, they are attacked by epidemics.

14. *Small-pox.*—In a preceding abstract we have given the annual deaths from small-pox from 1869 to 1878, and, to complete the series, we shall add those for the succeeding years, which were as follows:—

	Small-pox Deaths.
1879	49,489
1880	9,145
1881	6,749
1882	6,379
1883	12,103

The data show that small-pox is a true epidemic in the Punjab liable to periods of great increase in severity, and although of late years there was some hope that a reduction of mortality to about one-half of the usual rate might have been due to extended vaccination, the great increase of 1883, it is to be feared, may show a return to the usual high average rate.

15. The disease was very extensively prevalent in 1883. Deaths from it was registered in all the 32 districts, and out of 49 towns 37 suffered, and yielded an aggregate death-rate for the whole town population of 1·28 per 1,000. The country rate was 0·64 per 1,000. An additional proof of the wide-spread prevalence of the disease is afforded by the fact that 305 registration circles out of 446 returned small-pox deaths, but, as usually happens, the outbreaks were purely local, for all the deaths were reported from 2,661 villages out of a total number of 34,973. The total small-pox death-rate in 1883 was 0·64 per 1,000, while the average five years' previous rate was 1·27 per 1,000, including, of course, years of great severity of the disease.

16. Nearly the whole mortality in 1883 fell on the younger ages. Of children under one year of age 3,056 died, and of those at one year and under 12 there died 8,571, so that, with the exception of 476 deaths, the whole mortality of the year was yielded by children under 12 years of age.

17. The following abstract gives the monthly prevalence of small-pox in 1883:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	1,155	July	1,066
February	1,253	August	596
March	1,434	September	393
April	1,277	October	294
May	1,489	November	682
June	1,478	December	1,070

This table shows the usual increase of small-pox during rise of temperature.

18. *Vaccination Report.*—This report, which has been separately submitted to us, is purely departmental, and gives a very full account of the year's work, but we are not in a position to do more than discuss briefly the results so far as these concern the small-pox death-rate.

We have already seen that nearly the whole year's mortality fell to the lot of children under 12 years of age, and it follows that, in 1883 at least, the small-pox epidemic was essentially limited to these ages. What then was the relation between these young ages and the year's vaccination work? We have already seen that the registered births of the year were 734,912, and this number constitutes the main element, as is shown by the death ages, by means of which the vaccinator can hope to diminish small-pox mortality. Although, of course, attacks of small-pox prevented in 1883 may have been due to vaccine operations performed in previous years, still there ought to be a certain current relation between the numbers born in any one year and the numbers successfully vaccinated. If this be admitted, the results for 1883 would stand as follows:—

Births, 734,912.	
Successful vaccinations, under one year	421,081
" " over one and under six	150,326
" " other ages	10,432
Total	581,839

It will be seen that in round numbers four infants out of every seven born were successfully vaccinated during their first year, and that all the vaccinations, with the exception of 10,432, were effected at ages under six.

If the preceding five years' work be taken into account we shall obtain perhaps a better idea of the extent to which vaccination has been successfully carried out. This stands as follows:—

Average annual successful vaccinations	359,097
Ratio per 1,000 of population	19·06
Average annual small-pox deaths	23,389
Ratio per 1,000 of population	1·24

If there were no deaths the entire population of the Punjab would at this vaccination rate be protected in about half a century. But as the total successful operations had increased in 1883 to 31·08 per 1,000 of the population, the progress of protection was in a much higher ratio.

19. Of late years, the Punjab has been divided for vaccination into two divisions, "eastern" and "western," within which the average number of vaccinators employed in 1883 was 275, whose work

was inspected by Deputy Sanitary Commissioners, Civil Surgeons, and Native supervisors. Since the new arrangements came into operation, vaccination has been more rapidly carried on, and there was every prospect of a lower death-rate from small-pox, until the rise in 1883 to nearly double the rate of 1881 and 1882 threw doubts on the future. There are many things about small-pox which have yet to be learned, and amongst others this very matter shown in the Punjab experience, which, however, is not peculiar to India, namely, how it happens that with an improved and extended vaccination service the death-rate should suddenly duplicate itself. We have no present means of knowing, but in this as in other sanitary questions we must in the meantime be guided by experience. We must go on in improving the general sanitary condition of the population, to render the people less liable to epidemics, and the efforts of the vaccination staff must be more exclusively directed to the protection of infants, for until the births are overtaken by the vaccinations we shall have no right to complain of occasional epidemics of this disease.

20. *Fevers.*—In a preceding tabular statement we have dealt with the relation of epidemics, including those of fever, to food scarcity in the Punjab, and we shall here continue the figures down to 1883.

Years.	Deaths from Fever.
1879	472,939
1880	327,727
1881	355,279
1882	346,680
1883	306,185

Scarcity of food began in 1877, and continued for a year or two thereafter, and the figures show a very large augmentation of fever mortality in 1878 and 1879. We have referred to these facts because they have an important bearing on the question as to whether fever mortality in this province is diminishing, which would have to be answered in the affirmative on the mere figure data in the present Report. These show apparently that the fever death-rate of 1883, which was 16·25 per 1,000, was very decidedly under the previous five years' rate of 21·94 per 1,000. But these years include the famine period. Compared with the three subsequent years given above, namely, 1880-81-82, the rate for 1883 shows a reduction of above two per 1,000, which would be so far satisfactory if it really were due to the advance of sanitary improvement. This, however, is doubtful, for the Sanitary Commissioner appears to have shown that, just as the great fever-rates of 1878 and 1879 were due to the accidental intercalation of food scarcity, which increased the susceptibility of the people to the action of ordinary fever causes, so the lower death-rate of 1883 was mainly due to the reduction of rain in that year.

21. There are 32 stations in the Punjab at which rainfall is registered, and, in the present Report, the total amount of rain registered at all stations is compared with the total fever deaths of the year. This method of dealing with the data is open to the obvious objection that it makes an average out of local extremes, and so loses sight of the influence of topography and local sanitary condition on the amount of fever. The third quarter of the year is the time of heaviest rain, and the fourth quarter the time of highest fever prevalence. This appears to be a general law for the country as a whole. The highest fall in the third quarter of 1883 showed an aggregate of 440 inches, which was much below the average of most years, and, as we have already seen, the same year's fever deaths numbered 306,185. But, to show the defects in this method of dealing with the rainfall as a whole, it is only necessary to take the year 1875, during the last quarter of which the aggregate rainfall at the 32 stations was 920 inches, or more than double the amount of 1883, but, nevertheless, the year's fever mortality with this rainfall was 279,825 deaths. The conclusion, therefore, is, that the effect of rainfall on epidemics of fever is mainly local, and is related to local topography, including soils and subsoils, as well as sanitary conditions.

22. The fever death-rates in the districts varied between 5·91 per 1,000 at Simla and 29·27 per 1,000 at Muzzaffargarh. Nearly all were under the preceding five years' average, but it must be stated that in one district, Mooltan, where the usual rainfall averages 7·17 inches, an amount not likely to influence injuriously the fever-rate, the average five years' rate including the scarcity years, was 20 per 1,000, while in 1883 it was 20·85 per 1,000, the same rate, or nearly so, continuing throughout the entire period, pointing, in all probability, to other elements of climate outside rainfall as affecting the current fever mortality.

The result which we have aimed at in this discussion is to obtain, as part of the current year's sanitary history of the Punjab districts, the local rainfall in relation to the local fever death-rates.

23. In 1883 fever deaths were registered in all the 49 towns, and yielded a death-rate of 13·89 per 1,000, and the rate for the country districts was 16·43 per 1,000. Of the 446 registration circles all returned fever-deaths, with the exception of one circle in Hazara.

The monthly prevalence of fever is shown in the following abstract:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	38,242	July	20,754
February	28,218	August	21,382
March	25,822	September	20,808
April	21,454	October	24,043
May	24,241	November	27,144
June	24,541	December	29,516

Fever prevalence was very extensive. We have seen that all the districts and all the registration circles with a single exception returned deaths, and out of 34,973 villages deaths were registered in 26,624. Many of the villages are small, and it is not improbable that every village yielded fever cases, although all did not register deaths.

For a number of years past an inquiry has been in progress into the connection of fever mortality with irrigation works in 48 villages situated on the West Jumna Canal (25 in Delhi and 23 in Karnal), and the following abstracts give the facts up to the present time:—

Villages.	Population.	Total Deaths per 1,000 of Population.				
		1879.	1880.	1881.	1882.	1883.
Delhi - -	27,983	65	47	58	46	37
Karnal - -	15,153	76	44	44	37	32
Province - -	18,842,264	38.	27	30	27	25

For agricultural populations these rates are still high, but it is satisfactory to see that they are falling. During the five years in the table there were only 11 deaths from cholera in all of them, and by far the most important assigned death-cause was fever, the annual deaths from which stood as follows:—

Villages.	1879.	1880.	1881.	1882.	1883.
Delhi - - - -	1,481	1,036	1,192	346	712
Karnal - - - -	867	511	447	395	307
Total fever deaths - -	2,348	1,547	1,639	741	1,019
Ratio per 1,000 of population	54·6	36	37·7	17	23·6
Ratio of province - -	25·1	17·4	18·8	18·4	16·25

These fever-rates are excessive, although apparently undergoing reduction, but without a detailed sanitary inspection of the villages it would be impossible to assign the amount of fever due to irrigation. When compared with the ratios for the province during the same years, they throw suspicion on irrigation, to say the least of it.

24. The Report contains no new information on the local causes of these fevers, but their nature may be easily inferred from the inspection reports, which will be noticed in the sequel.

25. *Bowel complaints.*—Deaths under this head were registered in all the districts, in 421 out of 446 registration circles, and with one exception in all the 29 towns; but comparatively few of the villages suffered, only 4,209 out of 34,973. The deaths registered were 14,607, or 0·77 per 1,000, against a previous five years' average of 1·31 per 1,000. The bowel complaint mortality for the country circles was 0·68 per 1,000 of the population, and for the towns 2·06. It may be remarked that the reduction of 1,353 deaths in 1883 from the number of the preceding year co-existed with a reduction in the deaths from cholera. The mortality by months stood as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January - - -	1,162	July - - -	1,270
February - - -	858	August - - -	1,345
March - - -	813	September - -	1,437
April - - -	934	October - - -	1,498
May - - -	1,426	November - -	1,456
June - - -	1,329	December - -	969

There is nothing under this head calling for remark.

26. *Injuries.*—Deaths so classed include 257 suicides, 303 wounds, 2,444 accidents, 1,359 deaths from snake-bite and wild beasts. To snake-bite alone were due 1,189 deaths, the largest number so registered during the last five years, and within this term no fewer than 5,001 deaths have been assigned to the same cause. With an increasing annual death-rate, it would appear as if more activity in the destruction of venomous snakes were necessary.

Deaths from hydrophobia amounted to 117, and of other deaths from wild animals 16 were caused by jackals, 14 by stings of scorpions, five by wolves, four by bears, and one by a tiger.

27. Deaths registered under the head of "*all other causes*" were 137,293, and of this number 30,681 deaths were distinguished as having been due to chest diseases, which appear to be most prevalent and fatal during the winter and early spring months, when cold and rapid temperature changes prevail. We may here repeat what we have formerly said, that the Sanitary Commissioner is doing good service to the public health cause in the Punjab by rescuing these deaths from the general confusion during recent years; for in so doing, he has shown that climate has a very

important influence at present without adequate compensation in local habits on the public health of the province, and that the mortality entered under this new head is of far more importance numerically than the mortality from cholera. Apparently the next step in this direction would be to form some approximate estimate of the relative proportions in which different forms of chest affections contribute to the total mortality assigned to these diseases.

28. *Sanitary works (Civil).*—This section of the Report gives a brief abstract of the sanitary work done in the course of the year in municipal towns within the districts, and also a few notices of village work which are of importance not so much from their extent as from the fact which they indicate, namely, that some kind of a commencement has been made in dealing with the sanitary state of villages in the vicinity of stations and municipal towns.

29. The year's expenditure is given for 201 municipal towns, in the 32 districts, and the best way of showing the rate of sanitary work and progress in them will be to extract from the Report the following table, which shows under one view the expenditure incurred under the usual heads of improvement, and the annual increase of each item :—

	1880.	1881.	1882.	1883.
	Rs.	Rs.	Rs.	Rs.
Conservancy establishment	332,194	339,118	415,276	441,293
Paving	62,914	54,448	74,039	79,297
Roads and bridges	215,389	228,801	267,427	258,033
Drainage and sewerage	178,046	88,965	177,683	109,838
Water-supply and improvements	85,582	85,629	122,792	282,947
Widening streets	578	43,617	35,231	20,446
Latrines	25,063	24,160	13,044	18,293
Repairs of ditto	6,207	9,999	7,738	9,833
Total	961,872	909,637	1,103,290	1,219,771

From these data it follows that steady progress is being made in sanitary work, so far as this is indicated by expenditure.

We have not the vital statistical data corresponding in area with that included under the expenditure; but if we take the data for the 49 chief towns, with their population of 2,316,383, it would appear as if the money had been well spent, for we find that the previous five years' average death-rate, which had been 47 per 1,000, was represented in 1883 by a ratio of 30 per 1,000 from all causes, and that these towns had only five deaths from cholera among them. Their cholera death-rate in 1883 was 0·003 per 1,000, while the district rate was 0·01 per 1,000, or about thirty-three times greater. In these comparisions, however, we must bear in mind that there was no epidemic of cholera. But the facts, as a whole, appear to show that the public health is improving.

30. We shall next abstract from the Report a few details showing the kind of works executed during the year. The Public Works Department had finished a covered drinking water tank at Deobánd outpost, and drinking water tanks had been completed on a road in Rawul Pindi division. The new water-supply for Amritsar city was well advanced, but little had been done with the intramural drainage scheme. The following account is given of the extramural drainage scheme of this city :—"It is hoped, by the end of the official year, the outfall channel from the city of Amritsar "to the Hudyara Nala, a distance of 12 miles, will be completed. This channel has a width of "25 feet at the head, and 45 feet at its tail, and the bed of it at the head is 13 feet below the circular "road round the city walls, and is so designed as to carry off all water which now lies around the "city of Amritsar and its vicinity."

The only remark suggested by this account, and in the absence of necessary details, is the expression of a hope that methods may have been adopted to prevent injury to health by the exposure of a large area undergoing evaporation and drying up. On the other hand, it is satisfactory to learn that the filling up of the deep surrounding ditch has been undertaken by the municipality, and that the surface gained will be laid out as a garden. Plans for draining Sialkote city have been completed and are waiting for orders. A water reservoir for Simla was under construction. A large water tank for a fair town in Rohtak district was nearly completed.

31. The municipal reports contain information of interest to the future progress of sanitary works. In Delhi road making and surface drainage made progress during the year. Drain cleaning was carried on, and some of the sewers were periodically flushed. The municipal committee had obtained sanction to send their late engineer to England to obtain skilled opinions on their proposed works of drainage and water-supply. The conservancy of Delhi was considered satisfactory, except in places where cattle are kept, and a sub-committee had been appointed to consider the subject of municipal cattle stables adopted some time ago in Bombay. Roadside trees were maintained. There are 255 carts for conservancy purposes, but with 45 public latrines in use there appears to be considerable difficulty in dealing with the night-soil after removal. At present it is pitted with lime, but after three years' trial it has been found to be not a remunerative process, and it causes nuisance. It has been determined to trench the whole of it, which ought to answer as well as afford a profit if it be properly managed. Only Rs. 731 were realized in 1883 from sale of manure. The death-rate of Delhi, which had averaged 64 per 1,000 in the previous five years, was 40 per 1,000 in 1883. There was no cholera, but above 50 per cent. of the deaths resulted from fever. In Delhi district "no "village committees have been formed. Whatever action is necessary is taken by tahsildars working

" under the orders of the Deputy Commissioner, zaildars and lambardars being the agency usually " employed."

32. In Gurgaon a number of small towns have been undergoing improvements by the aid of municipal committees. The work has been chiefly conservancy. The Sanitary Inspectors have obtained, in a number of instances, more attention on the part of village officers to the condition of villages.

Improvements in drainage and water-supply have been carried out in several towns in Karnal. Many villages had been inspected by vaccinators, and manure heaps removed from them.

33. In *Hissar* " the conservancy arrangements of all the municipal towns are satisfactory, and each " municipality has, as far as its funds permit, sufficient establishment to keep the towns clean, surface " drains have been cleaned, and wells cleared out."

Similar improvements are reported from *Rohtak*, *Sirsa*, and *Umballa*.

34. The *Ludhiana* drainage scheme has been in abeyance from want of funds, but steps have been taken to prevent the inhabitants from converting the existing deep flood water drains in the streets into cesspools for house filth. All wells are cleansed annually, and a large number have been provided with covers to keep out leaves and other kinds of impurity. " A splendid tank " was under construction at Khana. The conservancy establishment was on an efficient footing, and all the manure collected by it is speedily sold.

All village sites " are brought under cultivation, no filth or refuse is allowed to be collected on " spare sites. Pillars have been erected 200 yards away from villages as boundaries beyond which " filth is deposited and the calls of nature obeyed." The sale of manure has realized nearly 500*l.* a year for Ludhiana.

35. *Simla.*—The water-supply works for this large hill station had been advanced, and the method of removal of house sewage, which we formerly discussed, by iron pipes downwards to a favourite waterfall and below it is now under trial. It now remains to be seen whether the objections which had been raised against this scheme have been obviated, or whether the system of trenching or sewage irrigation would be better.

Improvements in surface drainage, in water-supply, and in conservancy are reported from Jullundur, Hoshiarpur, and Kangra districts.

36. *Amritsar.*—The municipal report gives some further information about the drainage works about to be commenced. Their object " is to dig intercepting channels round the city, to catch and " carry off, at once, rain-water to a distance of 12 miles from the city. The scheme, when complete, " will be an immense boon to the city, as it will, by rapidly carrying off the rainfall, prevent the " rise of the subsoil water, which is at the present time quite close to the surface, and an undoubted " cause of sickness." In a former Memorandum we discussed at length the relation of the water-logged condition of the subsoil to the fatal Amritsar fever epidemic, and we must hope that the proposed works may serve their object in removing the subsoil water.

" Within the city walls much has been done during the year towards improving the drainage." It appears that large underground sewers had been laid down, and that the same result followed from them as formerly did in London. " One sewer, when opened, was found almost choked up with " about four feet of solid black putrid matter." These sewers must apparently have been built to remove the rain-water, which usually falls for a few days only in the year in sufficient quantity to cleanse a sewer of these dimensions. With plenty of water constantly flowing through them they might have been kept clean. But, as is proved by experience, the best way of removing the rainfall which occurs in great amount only within a short period of the year is to provide for this event over the surface.

One of the sacred tanks was cleared out in the course of the year, for the first time within living memory. The work was done by some two thousand of the people, who removed about three feet of sludge from the tank bottom and carried it up the steps to the tramway for removal. In the course of the year above 2½ millions of cubic feet of earth had been used in partially filling up the city ditch. This earth and the city sweepings were removed by a tramway, the materials for which were obtained from England. It is on the two-feet gauge, and appears to do its work quickly, effectually, and in a cleanly manner. The cost is also very much less than by carts. For the time the tramway had been in use, the gross saving over the outlay incurred for the usual methods of removal had been, for conservancy Rs. 5,849, city ditch Rs. 7,109, and making all deductions for wear and tear, &c., there had been a clear profit of Rs. 8,000, a result which shows that even in a country where labour is of the cheapest, there may be large savings by a judicious use of mechanism. In the present case the savings will have repaid all the capital expended in six years.

In a former Memorandum we showed how important the experience of fatal fever epidemics in Amritsar was to the questions involved in the fever etiology of India, and now that sanitary work has been taken up in earnest, it will be of great importance to watch carefully the results to health.

37. Improvements in surface drainage, paving, water-supply, &c., are reported from 15 municipal towns in Gurdaspur district, in 14 of which an aggregate sum of Rs. 4,425 was realized by the sale of manure. It is not much, but still it shows what can be done in this direction.

In this district improvements are reported in a few villages.

38. *Dalhousie sanitarium* in this district appears to be losing its reputation. " The water-supply " is notoriously imperfect, and urgently requires seeing to. . . . . The drainage of the bazaar " is very defective; it has gone on from bad to worse year after year." And then follows a state-

ment which shows how this deterioration has taken place, and the administrative defects to which it appears to have been due. "It is clear that the sanitarium has declined in effectiveness. The "place has become now popular, the bazaar has increased in size, and there has been a constant "change of offices, it only of late having been the rule to keep the Assistant Commissioner in charge "for two years. Houses have been erected to which no system of conservancy could be said to "apply, and the municipality have not always been so much on the alert as was advisable. The "supply of sweepers was insufficient, and they were not actively supervised. The result was that "though here and there private latrines were erected and used, as a rule all the house and stable "refuse was simply thrown down the hill side, polluting the air and the water-supply. Each hill "was more or less in need of sanitary reform, and the bazaar and the ground below the bazaar were "filthy to a degree." Steps had fortunately been taken to remedy this state of matters, which ought not to have been of possible occurrence at a place set apart for the recovery of health. But if the facts stated by the Sanitary Commissioner in any degree represent the usual course of matters at sanitaria, it need occasion no surprise that cholera, enteric fever, and hill diarrhœa attack people who, in leaving the plains, vainly imagined that they had left the predisposing causes of these diseases behind them.

39. *Lahore.*—The new city drainage works were completed, and a considerable extent of road making and repairing had been carried out. "The drainage of the main streets in the city is all "that can be desired." The city conservancy has been improving, "though much still remains to "be done." The water-supply requires to be extended.

Some attempts appear to have been made towards the sanitary improvement of villages and village sites in Lahore district, but this all-important work is still in its infancy. The town manure was sold in 1883 for 688*l.* The population of Lahore is 97,208, and that of the suburbs 41,670, and it is worthy of remark that the five years' average death-rate of the city, which had been 45 per 1,000, had fallen in 1883 to 28 per 1,000, while the suburban five years' rate of 36 per 1,000 had fallen in the same year to 19 per 1,000. It is, of course, impossible to affirm that these great reductions have been all due to sanitary work. All we know is that work has been done, and the death-rates have undergone a very remarkable reduction.

40. Besides the usual conservancy operations, no sanitary works of importance have been carried out at Sialkote, Gujranwala, Ferozepore, Rawalpindi, Jhelum, Gujrat, or Shahpur. That good work in this direction is being done may be taken for granted, as considerable sums are being realized by the sale of town manure. Improvements in surface drainage have been more or less attended to in these districts, and drainage schemes for Sialkote and Ferozepore were under consideration. But it may not be out of place to suggest that works which render necessary such proceedings as the following can scarcely take rank as sanitary works:—"In the Rawulpindi municipality openings "have been made at convenient distances" in the underground sewers to admit of their being "properly cleaned, and to these openings substantial iron sewer gratings have been affixed for the "prevention of accidents. Hitherto, owing to the absence of openings, it has not been possible to "keep the sewers clean." Apparently works of this class have been intended to carry off rain-water, and in the Punjab are only of use for a few days in the year on account of the sparse character of the rainfall. In such climates, as we have often stated, surface provision for the rain would apparently be sufficient.

41. The water-supply of *Murree*, in Rawalpindi district, "is capable of much improvement." This is an unhealthy sanitarium, subject to cholera epidemics. Some steps in the way of sanitary improvement were being taken in the villages of these districts, but not much, we fear, has been done as yet.

42. *Mooltan* appears to be under an active sanitary administration. Streets have been paved and surface drainage works carried out to remove the rain-water to a distance. Wells had been cleaned out. The municipal committee appears to have laid hold on the right method in adopting the principle of ward supervision by members appointed for the purpose, and it was hoped that before the end of 1884 the conservancy system would have been entirely remodelled and the most recent improvements introduced. The five years' death-rate for the city, which had averaged 36 per 1,000, had fallen in 1883 to 29 per 1,000.

43. In *Peshawur*, the new water-supply, which is open and carried alongside a foul water drain, was all but completed. Great improvements are reported in the conservancy, and there appears to have been good work done in surface drainage. In 1883, Peshawur had a death-rate of 34 per 1,000 against a previous five years' average of 6 per cent. Part of these lower death-rates were, however, due to absence of cholera, and in the Punjab the reduction must not be altogether credited to sanitary improvement.

44. In the other districts there is not much requiring notice. The chief measure in use appears to have been cleansing, and in some villages this work appears to have been well done. We may, however, notice the case of a fine tank at Kot Naina, in Gurdaspur, which had been useless from leakage, but had been restored to use by puddling the bottom, for the purpose of suggesting that if the water falls short and the surface is cracked by drying, the defect may be reproduced. In such cases it is better to trench the bottom and to incorporate it with silt and clay.

45. Under the head of *General Remarks and Personal Proceedings* are included official documents on sanitary matters which do not call for remark, except that they show a steady desire to forward the work of registration, vaccination, and general sanitary improvement. Difficulties in dealing with

the village problems are not over-estimated, and by way of spreading information among the people, 10,000 copies of Dr. Bellew's excellent sanitary dialogue were sent to the Punjab Government for circulation in the Native States, besides 2,570 copies distributed among the district officers.

Among the rules laid down for the guidance of village Sanitary Inspectors, they are to note the sanitary condition of villages, arrangements for storing village filth and refuse, steps taken for the protection of wells and other water sources, for keeping open ground round villages free from filth, for filling up hollows, pits, &c., for burial or disposal of dead, and generally the arrangements made for the cleansing of village streets and cattle pens. Similar duties have to be performed for municipal towns when the vaccination officers are disengaged from their special work.

The Sanitary Commissioner appears to have done a large amount of useful inspecting work in the course of the year, and his notes, as might have been expected, contain evidence of important sanitary defects, as well as of real advance in the way of improvement. He very properly insists on the necessity of vesting all the town filth in the municipality, to ensure the double object of more effective cleansing, and recovery of part of the cost by the sale of manure. But this principle must be thoroughly applied, for he shows that where part of the town refuse is so appropriated and part left to be removed by private persons, the cultivators prefer to do this rather than pay.

Another point of experience is worthy of note. It appears that the municipal committee of Delhi buried their manure in pits in the expectation that it would be improved in value. This, however, has not been the case. As part of the plan of city cleansing where hand labour and carts have to be depended on, it is absolutely necessary that there should be facilities for the daily removal and utilization of the daily town refuse, either at a distance by cultivators who might buy it, or by the municipality itself on its own ground. An area might be fertilized by digging in or ploughing in the day's manure, and this would imply access to a sufficient area to receive the refuse for a crop season. Ground area is required, whether for this purpose or for sewage irrigation, where the town may have been drained. This precaution would, of course, be unnecessary, if arrangements were made with contractors or cultivators for the daily removal of the city refuse to a distance.

We are glad to learn that in a number of instances, the local defects pointed out by the Sanitary Commissioner had been dealt with.

46. On the general question of sanitary administration, the following remarks made by Mr. Bellew appears to be worthy of consideration by the executive authorities. After stating that everywhere in the course of his inspections he was listened to with intelligent interest by the people, "but every-"where the power of initiation was wanting, and most completely so in the villages," he proceeds, "In the case of the municipal towns, I think the members of the municipal committees should "understand that they are expected to take a more active part in the discussion and examination of "sanitary works proposed for or undertaken in their towns, so as to ensure the greatest amount "of information on any particular project being considered in relation to the bearings of local "conditions and peculiarities; the neglect of this duty often leads to miscarriage of well intended "projects of sanitary improvement, and to much waste of municipal funds." He exemplifies this by cases in which the object to be attained was alone kept in view, and where the sanitary improvement effected had led to evils of another kind and to waste of money. This experience shows the necessity for sanitary supervision; but it is not peculiar to India. The object aimed at is one thing, but the way of dealing with it is quite another thing. Even in England there have been no unfrequent reclamations on the part of persons whose sanitary surroundings have been deteriorated by their neighbours' sanitary works. As regards villages, Mr. Bellew says that "much good may be promptly "and easily effected if the district Boards of Health would bring their influence to bear upon the "village headmen, in the matter of seeing to the enforcement of a proper system of village con-"servancy on the lines already sanctioned by Government, and now steadily spreading in all parts "of the province, namely, by the establishment of fixed sites enclosed within low mud walls at "convenient distances outside, and clear of the village area, for the collection and storage as manure "material of all village sweepings, filth, and litter, instead of, as is at present generally the case, "allowing the formation of dung-heaps in and about all parts of the village, and altogether neglecting "the cleanliness of their courts and passages."

47. Now that local self-government has been initiated in the Punjab, we may look for its gradual development in time, but there are some remarks on this subject in the Government proceedings which appear to represent the present position of sanitary possibilities, and which we shall quote, premising, however, that some of the difficulties are matters of opinion on the part of local officers:—

"The Lieutenant Governor holds that it is a mistake to suppose that sanitation can be advanced in "agricultural districts by the authoritative enforcement of rules most of which are greatly in advance "of the social condition and requirements of the people. . . . . When, therefore, rules regarding "sanitary improvements are placed before the people, it is necessary distinctly to explain unless "such rules are framed under the provisions of a legal enactment, that their enforcement depends "upon the people themselves, and that, in sanctioning or approving of such rules, the Government "merely assents to the promulgation of general principles, which the inhabitants of towns and "villages would do well to adopt with regard to their own interests, if they thought fit to do so." And then as to the future:—"In process of time, when the new local boards have been established "throughout the province, the question of sanitary improvement will, the Lieutenant-Governor "trusts, form one of their most important duties, and be regarded by them with special interest. "The Bill for local self-government in the Punjab now under consideration will give power to take "measures for preserving wells, &c., from pollution, and to institute measures likely to promote the "health of the people. When the people fully appreciate the benefits of sanitation, the task of

" supervising officers of Government will be comparatively easy. Meanwhile the function of the " Sanitary Department is to make suggestions for their willing adoption, and to educate them in " measures of sanitary reform."

These views of the Government are in conformity with experience. Sanitary improvement in its social aspect means a change or abandonment of long-inherited unwholesome habits of life, and in any community sanitary enactments will always be the most effective which are the expressions of known and acknowledged local necessity. Even in England we have had some experience of the opposition and inconvenience arising from compulsory enactments which are not the expression of local convictions. This is a final principle which must sooner or later be acknowledged, but if it be accepted, it in no way interferes with voluntary discussion and its resulting spread of knowledge among the people whose interests it is intended to serve. Neither does it interfere with local and personal influence in the matter of local improvements. So that it is at present in the power of local officers in India to effect a considerable amount of improvement in the more important points of sanitary work, and, by so doing, not only to lessen the amount of epidemic disease, but to pave the way for sanitary law becoming the expression of acknowledged local necessity. We have quoted Mr. Bellew's statement already, and it appears to us that what he desiderates could be to a very large extent accomplished by advice or by expression of opinion on the part of the local officer, even in the absence of legal compulsion.

48. The section on *personal* proceedings is followed by an interesting abstract of inspections made by the Deputy Sanitary Commissioners of the Eastern and Western Districts, in which the sanitary state of a considerable number of towns and villages, the works in progress, the recommendations made, and their results are stated. The information is of the usual character. It shows the presence of important defects, but also that effective sanitary work is of possible execution, and that it is making real progress. The information conveyed is of hopeful character. The Civil Surgeons in the course of their inspection tours visited 43 towns and 125 villages, but no particulars are given about their sanitary state.

49. Before concluding this Report we may state that there were no deaths among 160 children in the Lawrence Memorial Asylum at Murree, and one death from an unassigned cause among 426 children in the Lawrence Military Asylum at Sanawar. The chief admission causes were those of the febrile disease group. At the Sanawar Asylum there were several important sanitary defects especially connected with the milk-supply, water-supply, and other matters of hygiene, which appeared to require attention.

In conclusion, this Report shows clearly that sanitary improvement is making considerable progress in the Punjab. Indeed, the most important section of it is devoted to sanitary detail, and it is satisfactory to find that so much information was at hand on this, the most important of all the heads. Were it not for the very uncertain nature of one of its death causes, cholera, we might have congratulated the Government in having made a distinct advance in improving the health of the people. As the case stands, the year's experience may be accepted as hopeful, and we must repeat the hope expressed by the Lieutenant-Governor, that the new local boards may realize the importance of an efficient discharge of the sanitary duties devolving upon them to the interests of their fellow subjects, not forgetting, at the same time, that next in importance to entering on work is to take care that the work is efficiently done, and that the new authorities do not enter on a wrong groove at the beginning. An important remark under this head is made by the Civil Surgeon, Delhi district, who deprecates the spending of large sums of money on costly waterworks, which may not be quite necessary, especially where the local funds are limited, and where the object aimed at may be possibly met by improving existing sources of supply. This is a question of ordinary sanitary economics, and involves the allotment of available funds in such a manner as to secure the greatest public advantages, bearing always in mind that the works which skilled inquiry may pronounce to be the most necessary should be first taken in hand. But there are many other ways in which mistakes can be made besides in money expenditure. And these considerations point to the necessity of efficient inspection and supervision as part of the sanitary administration.

4th June 1885.

No. 6.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER for the NORTH-WEST PROVINCES and OUDH for 1883.

1. The statistics of the North-West Provinces and Oudh for the year under review are based on the census population of 1881, which was as follows :—

Males	22,912,556
Females	21,195,313
Total	44,107,869

According to race there were—

Hindus and lower castes	38,171,728
Muhammadans	5,922,886
Native Christians	13,255
Total	44,107,869

2. Out of this population the births registered were—

Sexes.	Registered Births.	
	Numbers.	Ratio per 1,000 of Population.
Males	950,932	21·56
Females	850,469	19·28
Total	1,801,401	40·84

This abstract presents a very high birth ratio, and yet the Sanitary Commissioner informs us that "the registration is nominal, one line of the register being given to each birth, and the father or "guardian's name recorded against it, so that fictitious entries are not likely to taint the record to "any serious extent." The Sanitary Commissioner is disposed to trace this high birth-rate to early marriages and fertility; but it appears to be not unlikely that the population on which the birth ratio has been calculated has been under-estimated. How can we otherwise account for such rates, in round numbers, as 44, 46, 48, 50, and 58 per 1,000, as are credited to some of the districts? There are only five districts out of 49 which registered rates under 33½ per 1,000. The average birth-rate for 107 municipalities in these provinces was 38·38 per 1,000, which it will be observed is less than the total rate of 40·84 for the provinces. Some of the municipalities return about a five per cent. birth-rate. The most likely explanation is that the population estimates are under the truth.

3. The following were the deaths registered in 1883:—

Males	652,901
Females	563,396
Total	1,216,297

equal to 27·57 per 1,000 of population. If we assume the nominal registration as approximately correct, the deaths, when compared with the births, would show an absolute addition to the population of 585,104, or 13·27 per 1,000. No doubt the district registration shows a large amount of good work done; but we can scarcely accept this increase as absolute. The probability is that if we accept the actual registered births as approximately correct, we should scarcely be justified in accepting the registered deaths as representing the total mortality of the year.

4. The results would therefore stand as follows. The total registered births are approximately correct. The registered deaths are fewer than the actual mortality. The ratios of births and deaths to population are not reliable, probably on account of under-estimate of this last. Nevertheless, the results are remarkable, because in these provinces, with a population of above 44 millions, that which has been considered as the most difficult part of the registration, viz., a record of births, has been approximately accomplished.

It may be useful to state how this has been arrived at, in the words of the Sanitary Commissioner, who considers that the continuance of this satisfactory result "is due chiefly to the introduction of "small hand registers, first supplied to the town and village watchmen in 1881. I have," he says, "examined many of these small books during the past year, and have found them better kept, as a "rule, than I had hoped for. They serve to record the happening of a birth or death at the time of "the occurrence, and the record always remains with the village watchman, so that it is now "comparatively easy to obtain a statement of the births or deaths which have happened in any "village for comparison with the population of the village. . . . The watchman, in place of a "verbal report as before, presents his local record to the circle mortuary clerk for extract of its "entries into the register." The watchman, in fact, performs, in a way, the duties of a district or sub-district registrar without his certificates, and hence the disease nomenclature has, properly speaking, to be entrusted to non-medical agents. It is, however, no small advantage to have got so far on the road to accuracy, while on this basis of record it may be found to be possible to rear a superstructure of more useful diagnosis of local diseases. We shall presently give a curious illustration of what takes place under the present arrangement of diseases, and of the errors to which it leads.

5. We shall analyse the facts a little more in detail to show the proportion of deaths to population of the same ages.
This is shown in the next abstract.

Ages.	Death Ratios per 1,000 of Population at these Ages.
Under 1 year	322·6
1 and under 5	55·0
5 „ „ 10	14·1
10 „ „ 15	7·3
15 „ „ 20	10·8
20 „ 30	11·3
30 „ 40	12·5
40 „ „ 50	17·3
50 „ „ 60	29·3
60 and upwards	45·1
All ages	27·5

This table gives the death-rates for known ages on the census population of 1881, and it will be seen that nearly a third of the children living died before the expiry of the first year. This fact, however, overstates the ratio, because of 1,301,401 births in 1883, 384,964 infants, or 213 per 1,000 of the births, had perished within the year, so that the second year began with 1,416,437 live children to enter on the life struggle. But this reduced number had to undergo further reduction before its fifth year of age was reached, for between the ages of 1 and 5 years 244,892 of children born had disappeared. The two numbers together amounted to a loss under 5 years of age of 629,856 lives, or nearly 350 per 1,000 of the births, and there remained for future use, 1,171,545 children at 5 years of age. This great loss of life in the earlier years of existence has always been a subject of interest in vital statistics from its co-existence with high birth-rates, and has led to the view that the latter are of the nature of a law, and prevent the excessive reductions from excess of deaths; or, as the Sanitary Commissioner puts it, "indeed so potent and numerous are these (death) causes, "that nothing but a very high ratio of births could suffice to provide against the exceedingly high "death penalty." It has been generally considered, besides, that high birth-rates and high infantile death-rates point to a weak surviving population, not well fitted to withstand the influence of disease causes in after life.

6. Cantonment registration is undergoing improvement. Nine of them, including a population of 112,809, returned an average death-rate of 32·39 per 1,000.

7. One of the most satisfactory announcements in regard to the registration in these provinces is that the weekly mortality tables for 18 municipalities, having an aggregate population of 1,736,311, were published in the provincial Gazette in 1883, often in the Gazette of the week following their completion. We advised this step to be taken as far back as 1864, and nothing will more conduce to a correct knowledge and appreciation of local diseases and their removable causes than a careful detail of the facts under Government authority, with such notes as the Sanitary Commissioner may think advantageous for the purpose of directing public attention to these causes.

8. We shall next give a brief account of the disease history of the year.
The following deaths were registered under the usual headings in 1883 :—

Diseases.	Registered Deaths.	Deaths per 1,000 of Population.
Cholera	18,160	0·41
Small-pox	138,641	3·14
Fevers	830,258	18·82
Bowel complaints	66,530	1·51
Injuries	20,978	0·48
All other causes	141,735	3·21
Total	1,216,297	27·57

As usually happens, the fever mortality formed in 1883 the principal element in the year's death-rate. Small-pox, notwithstanding the vaccination work of the year, had assumed the character of a great epidemic, while the assigned death cause of least importance during the year was cholera.

9. The relation of the cholera of 1883 in the conjoined provinces to the epidemics of seven entire years was as follows:—

Years.	Deaths from Cholera per 1,000 of Population.
1877	0·74
1878	0·52
1879	0·84
1880	1·07
1881	0·58
1882	2·02
1883	0·41

The year 1882 was one of great epidemic prevalence in various regions of India, and the crowded Allahabad fair was held early in the year. Cholera had appeared at several points of these provinces before cases of it occurred at the fair. It was moving from the north-western circles of Bengal, and in the course of the year part of the epidemic invaded the Central Provinces by passing southwards along two lines of advance, and another part crossed the Ganges and caused great havoc in Rohilcund, while the Doab comparatively escaped. The fair at Allahabad began to break up when cholera appeared there, but the disease attacked pilgrims along their return routes, although there was no evidence at the time that they had spread cholera among the people. But, whether they did so or not, the facts showed that the epidemic had preceded the pilgrims, although it is possible that the overcrowding and filth attending the dispersion of some three millions of people may have added to the severity of the disease during the onward movement of the epidemic, the pilgrims in this case becoming an added local disease cause. But there is nothing to show that on any of the routes they carried cholera in their own persons and so spread it. The disease had nearly died out by the end of 1882. There were 53 deaths in January 1883, 26 of which were returned from Sultanpore district in Bareilly, and 14 from Hamirpur in Allahabad. The remaining 13 cases were scattered over the provinces at great distances from each other. The epidemic was present in January, but in low intensity. In the course of 1883 deaths from it were registered in 46 out of 49 districts, showing its general prevalence. Out of 1,147 circles of registration, 516 returned deaths, but in these 1,147 circles all the deaths were returned from 2,536 villages out of a total of 105,421. The death-rate from cholera varied greatly in different parts of the provinces. Generally, the rate was much under 1 per 1,000 of the population, and in only 7 out of 49 districts did it reach and exceed 1 per 1,000. Banda in Allahabad division had, nevertheless, the very high rate of 5½ per 1,000, the greatest in the provinces.

10. The monthly prevalence of the disease was as follows:—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
January	58	July	4,551
February	40	August	3,248
March	184	September	1,794
April	930	October	892
May	2,084	November	140
June	4,228	December	16

We have in this table a numerical statement of a completed epidemic, apparently having its roots in the end of 1882, but only starting into activity when the month of April arrived, which is the usual epidemic course, culminating in June and July, and then declining, to die out in December.

11. The experience of this epidemic afforded several illustrations of the influence of epidemic intensity on the local death-rates. We have already stated that in very few of the districts did the death-rate from cholera reach 1 per 1,000. In Dhera Dun, which contains 366 villages, one village only suffered, and this to the extent of no more than one death. In Etawah, out of 1,478 villages, two yielded four deaths. The cholera death-rate in Etah was ·04 per 1,000, and was made up by 35 deaths in 4 villages out of 1,489 in this district. The cholera death-rate in Benares district was 1·38 per 1,000, and was the result of 1,283 deaths registered in 165 villages out of 1,946. In Banda district, which yielded the highest cholera-rate of the year, viz., 5·50 per 1,000, there are 1,166 villages, of which 305 were attacked, and 3,845 people died of cholera. These facts are only part of the usual epidemic history, and as sanitary and personal conditions remain much the same, they appear to show that local epidemic intensity exercises no unimportant influence on the mortality. The bearing of the facts on prevalent disease theories is obvious, and ought to lead to broader views being taken on the subject of epidemic diseases, for it is quite certain that none of the theories can be made to include the whole history, and that the effect of sanitary improvements which are not matters of theory, but of actual experience, are to a certain extent controlled by epidemic force.

12. Sanitary improvements have been proceeding slowly all over these provinces, and one consolatory fact is that the year 1883 yielded the lowest cholera death-rate which has been registered in the united provinces.

13. *Small-pox.*—In a preceding table we have given the annual death-rates from cholera since the union of the provinces, and the next abstract gives the corresponding death-rates per 1,000 of the population for the same years.

Years.	Small-pox death-rate per 1,000.
1877	0·8
1878	3·9
1879	1·7
1880	0·1
1881	0·3
1882	0·6
1883	3·1

These ratios show that small-pox is as much an epidemic disease in the North-West Provinces and Oudh as is cholera, and, moreover, that it is a far more fatal disease. This is shown distinctly by comparing the aggregate death-rates of the two diseases for the same seven years, as follows:—

	Aggregate death-ratios, 1877 to 1883.
Cholera	6·78
Small-pox	10·50

In round numbers, for every two deaths from cholera during these years there have been three deaths from small-pox, and this notwithstanding an active vaccination system extending over the country.

14. As already stated, there were 138,641 deaths from small-pox registered in 1883. The disease prevailed in all the divisions of both provinces, and of 1,147 circles of registration 932 returned small-pox deaths. The village returns are not complete, but, as they stand, 27,596 villages out of 105,421 suffered. Of 100 towns, all registered small-pox deaths except five. Out of the total mortality, 8,061 deaths, or nearly 3 per 1,000, were returned by the town populations.

15. The epidemic of 1883 was by no means equally distributed over the districts. In two of them, Ghazipur and Gharwal, the rate was 0·02 per 1,000, from which point it gradually rose until it reached the very high rates of 13·80 per 1,000 in Lucknow, 14·15 in Hardoi, and 17·53 per 1,000 in Bara Banki. Out of 49 districts, 10, including these, yielded the highest rates of the year, and are described by the Sanitary Commissioner as follows:—"These districts form a continuous "country of Oudh and Rohilcund north of the Ganges. And I think there is no doubt that, as a "matter of recent history, Oudh is the country of this province in which small-pox has greatest "power, and at the same time it is the portion of the province in which vaccination has made least "progress." A fact partly due to the opposition of the people to vaccination, which was culpably concealed by falsifying the returns of operations. On the other hand, there are three districts, Dehra Dun, Kumaon, and Gharwal, which had only 61 deaths from small-pox among them, an immunity comparatively which has existed for 14 years, and has, the Sanitary Commissioner thinks, been undoubtedly due "to a perfect vaccination of the people." The practical conclusion, of course, is that means should be adopted for increasing the efficiency of vaccination in Oudh, which was the chief seat of small-pox in 1883.

17. *Vaccination.*—The Report under review contains the usual departmental details regarding the vaccination service and its results. The staff for the year stood as follows:—

Superintendents of circles	3
Deputy superintendents	7
Native „	50
Vaccinators, first class	287
„ second „	352
Chaprasis and other servants	55
Total staff	754

The successful vaccinations and re-vaccinations performed by this staff amounted to 570,940, and the average cost of each successful case was 3A. 5P. Of the total successful operations of the year 565,351 were primary operations, at the following ages:—

Under one year	264,496
Over one year and under six	257,126
Other ages	43,729
Total	565,351

This shows a large proportion of the total vaccinations at the younger ages, but when the amount of work done during the first year of infantile life is contrasted with the registered births, which, as we have seen, amounted to 1,801,401, it is not difficult to see where the defects of the vaccination are to be found, and where a remedy has to be applied so far as it might by itself lessen liability to small-pox, and this lies in directing the work of the service as much as possible to the protection of infants under the first year of life, when small-pox is most fatal, and when the protection, once secured, passes onward to after life.

While calling attention to this matter we cannot, however, overlook the epidemic character of small-pox in these provinces, which has to be dealt with in the same way as must be followed with all epidemics, by the more complete removal of local disease causes, and by the general improvement in the life conditions of the population as a whole, and more especially in the care and management of infants.

17. *Fevers.*—Deaths classed under this head amounted to 830,258, yielding a death-rate of 18·82 per 1,000. Fever diagnosis is open to the usual objections that other fatal diseases attended by heat of skin are classed by the enumerators with fatal cases of true fevers. It is not likely, however, that the amount of error has differed within the last few years, and, if this be conceded, we must arrive at the not unsatisfactory conclusion that the registered death-rate, which under this head had been 26·22 per 1,000 during the five years preceding 1883, had fallen in that year to 18·82 per 1,000, showing a reduction of 7·40 per 1,000, and one of the sanitary problems of the year is to ascertain the cause of this great diminution of fever mortality.

18. Diseases which prevail epidemically have a tendency to irregular increase and diminution, and every observed fact which is likely to influence this course becomes of importance, not only as an addition to our knowledge, but for practical purposes also. We may here recall the fact that the amount of paroxysmal fever in a malarial country is influenced by temperature, moisture, and decomposition of organic matter in the soil. We may for the present purpose leave out the purely local causes, and also those connected with irrigation and defective drainage, which may be assumed as more or less constant elements in the question, the action of all of which was continued through the year 1883, as is shown by the fever death-rate of that year, and ask this question,—Which of all the known agents of increase of malarial fever had so varied in 1883 as to warrant a presumption that to this variation was due the reduction of the fever death-rate? On former occasions we have advised the preparation for the North-West Provinces Report of meteorological tables to enable the data to be compared month by month with the mortality statistics. This has not yet been done, and the information at our disposal in the present Report is only of a very general nature, but, such as it is, it may be taken as furnishing a clue to the reduced fever mortality of the year.

19. Notwithstanding the reduced death-rate, fever deaths were returned from all the districts, from 1,115 out of 1,141 circles of registration, and from nearly all the villages, 105,421 in number, and all the towns suffered. The district fever death-rate was 18·65 per 1,000, and the town rate was 21·40 per 1,000. There was universal prevalence of fever with less loss of life.

20. The following was the monthly mortality assigned to this death cause in 1883:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	74,286	July	62,716
February	63,390	August	65,810
March	67,637	September	63,744
April	71,333	October	67,648
May	72,472	November	73,950
June	70,526	December	77,146

The first peculiarity of this table is that it does not show so large an increase of fever deaths during the drying up months as is usually the case. The colder months yielded more fever deaths, and the relation of fever to rainfall is not so marked as usual. But, on turning to the section on meteorology, we find the following account of the monthly rainfall, which may be read alongside this monthly fever table:—

January.—Rainfall "about four times the average of former years."

February.—Rainfall "exceedingly light, and confined to the last week."

March.—Rainfall "exactly equal to average."

April.—Dust storms, and rainfall "decidedly less than the average."

May.—Rainfall, "the mean in May is 0·82 inch; in the 11 divisions in May 1883 it was 0·87, a "slight increase."

June.—"The rain was less than the mean in eight divisions by an average of 1·2 inches."

July.—"Rainfall in excess from 0·38 to 3·12 inches in four divisions; deficient in the others."

August.—"Rainfall was deficient everywhere in pretty equal proportions. The mean is 10·14 "inches. The average deficiency in 1883 was 6·45 inches over all the 11 divisions."

September.—"Rainfall in excess by 0·39 inch in Meerut, but deficient in all the other divisions, "and in Benares to about one half."
October.—"Defect in every division."
November.—Slight rain in three divisions, all the others rainless.
December.—The same distribution of rain.

The rainfall of 1883 appears to have been more equally distributed, and local rainfloods were absent. Irrigation was carried on as usual, but absence of undue rainfall with it led to this result, that while the fever mortality of the province was considerably less than usual, the irrigated districts returned lower fever death-rates than the average.

21. In former memoranda we have called attention to a fact, apparently established by sufficient experience in these provinces as elsewhere, that abnormal rainfall in districts under irrigation raises the fever death-rate, and in the present year's Report we have the converse of this experience, for as the following table for the 12 irrigated districts shows, deficient rainfall is attended by marked reduction in fever deaths. The table includes years of heavy rain with water-logging of the irrigated area. There was little rain in 1883, comparatively.

Years.	Fever Deaths per 1,000.	
	12 Irrigated Districts.	Corresponding Provincial Rates.
1878	29·1	22·9
1879	67·9	37·6
1880	28·0	23·1
1881	26·5	24·9
1882	26·3	24·9
1883	22·5	18·8
Aggregate	200·3	152·4

The irrigated district means include enormous death-rates. Two of them, Bulandshahr and Aligarh, during the year 1879, when the average rate for the whole 12 was 67·9 per 1,000 yielded perhaps the highest death-rates on record, the former, namely, 113·7, and the latter, 113·5 per 1,000 from fever alone. It is, however, satisfactory to have to record that these rates, in 1883, were represented by 19·1 and 17·0 per 1,000, about the average of the provincial rate of the year, which was 18·8 per 1,000.

So much for the scientific facts, so far as they are reliable, and these bear out our former contention that while in an undrained country abnormal rainfall increases the fever death-rate and defect of rainfall reduces it, precisely the same law holds good in irrigated districts, with this important difference, however, that as irrigated districts suffer from what may be called a higher fever tension than exists in non-irrigated districts in the same country, increase of rain which in these provinces generally would raise the fever-rate might at any time occasion an explosion of fever in the irrigated districts. For this result the only available remedy is drainage to keep the subsoil water moving at a lower level, more careful apportionment of water to the requirements of cultivation, and persistent attempts to improve the sanitary condition of villages and their vicinity, including the dwellings of the people. The preceding table shows that the aggregate fever death-rates for seven years for the 12 irrigated districts amounted to 200·3 per 1,000, and for the provinces as a whole to 152·4 per 1,000. The excess of fever deaths in seven years, due apparently to irrigation without drainage, and also to careless use of water, was thus 47·9 per 1,000, or about 6·8 per 1,000 per annum. If irrigation were so improved as to eliminate this excess of fever deaths in the 12 districts, the fever problem, as it presents itself in non-irrigated districts, would still have to be dealt with by drainage and improved agriculture and local remedies.

This is the result of experience, as regards fevers in these provinces, up to the present time.

22. *Bowel complaints.*—There has always been some uncertainty about deaths registered under this heading, on account of apparent anomalies in their distribution. In 1883 deaths from bowel complaints were returned from all the districts, and from 1,072 circles of registration out of a total of 1,147. The present Report does not give the deaths by villages, of which there are 105,421 in the circles; but as the whole registered deaths from this presumed cause amounted to 66,530, it is evident that many villages must have escaped deaths from bowel complaints altogether. There appears to be little doubt that the usual fatal diseases classed under this head are diarrhœa and dysentery, and these diseases are believed to be of such common occurrence that doubts have been expressed as to whether the registered deaths included anything like the real mortality. On the other hand, in the Report under review, it is stated that there are other internal diseases besides bowel diseases included under the heading. In consequence of the large mortality from bowel diseases in certain districts an inquiry was instituted, which resulted in the discovery that to an indefinite disease called *kaff* much of the bowel complaint mortality was due. This designation appears to include "inside" diseases generally, and in the present case it meant pleuro-pneumonia, because this affection is situated "inside" the chest.

It would appear as if an attempt might be made to separate chest diseases under a suitable heading with some advantage to the disease nomenclature, as has been done in the Punjab. As the registration stands the monthly bowel complaint deaths were as follows :—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	5,502	July	5,992
February	4,323	August	7,306
March	4,428	September	6,493
April	4,793	October	5,619
May	5,669	November	5,395
June	5,859	December	5,151

The death-rate for the country district population was 1·37 per 1,000, and for that of the towns 3·55 per 1,000, the general rate for the provinces having been 1·51 per 1,000. These ratios afford the only sanitary data on the subject, and they appear to show that bowel complaint mortality is connected in the towns with local insanitary conditions.

23. *Injuries.*—The total deaths from accidents and injuries were 20,973, or 0·43 per 1,000 of the population. Among these deaths were included 571 suicides of males and 1,625 of females, 12,182 deaths by wounds and accidents, and 6,595 by snake-bite and wild beasts. This last record is the largest of seven years.

24. Under the head of *all other causes* there were registered 141,735 deaths, or 3·21 per 1,000 of the population in regard to which nothing except the numbers registered is known.

25. The year's disease history in the present Report is concluded by an instructive table, in which are placed in parallel columns the death-rates per 1,000 from small-pox, fever, and bowel complaints for every one of 318 circles of registration. If the nomenclature were correct, this table would be a valuable addition to the annual disease history of these provinces, for it would enable the epidemic localities to be determined with approximate certainty. Its chief interest centres in the column of fever mortality, and this record continued year by year could not fail to yield information of high practical importance to the application of local sanitary improvements. Where means are limited, it is an axiom in sanitary work to direct the expenditure according to the proved need in each case. This table as it stands contains sufficient data on which to proceed. But a series of annual tables would enable us to see how sanitary work was taking effect, whether it was being done, and where there were defects in the procedure.

26. Under Section IX. (*Sanitary Works, Civil*) are given brief notes of expenditure incurred and sanitary measures carried out in 80 municipal districts. These measures are mainly improvements in paving, surface draining, conservancy, and in water supply. No large works appear to have been carried out. These cases are merely selected as examples, but the Sanitary Commissioner states that "during the year 1883, works of sanitary improvement were effected in almost every important "centre of population in the province. Wherever the means of improvement are available there "some proportion of the available income is expended for the improvement of the habited site or its "precincts. These improvements of every kind and character have been reported to me for "information." A comparison of the death-rates for five years preceding 1883 would apparently lead us to the conclusion that life was being saved under the existing sanitary administration and progress. Thus, the town death-rate in 1883 from all causes was 35·32 per 1,000, while the previous five years' ratio was 40·88 per 1,000, showing a reduction of 4½ per 1,000. But it is necessary to bear in mind that in 1883 no less than 21·40 per 1,000 was due to fevers. But after all is said about work done, the fever death-rate in these towns, many of them of very limited population, exceeds what ought to be the death-rate from all causes in improved localities.

All that the facts warrant us in accepting is, that sanitary improvements have been more or less initiated, but the work as such has yet to be done, and that it really lies not so much among the town populations as among the 41,351,376 people who occupy 105,421 villages, in regard to which we have no account of work done in the present Report. These bare numerical facts contain in themselves a statement of the difficulties with which the Government of these provinces has to cope in dealing with the epidemic death-rates. We have no desire to under-rate them, but they are no more than those which have everywhere to be encountered in attempts to improve the health and stamina of the working population.

27. In connection with this subject we may allude to the inspection reports of Superintendents of Vaccination. These are—with one exception, the report of Dr. Grant—confined to their special object, and do not call for remark from us. The inspecting work of the year has been, in fact, mainly directed to the future prevention of the disgraceful falsification of vaccination returns, which we must hope will not recur. In the course of his work Dr. Grant visited localities where fever had existed, and a brief abstract of his remarks will be sufficient to show the relation of malarial fevers to local causes. He says, in regard to the town of Chibrámau, that its population of 7,990 people had lost 570 from fever, which attained its highest mortality in October, during which month 135 died, notwithstanding an apparent deficiency of rain over the country. But, on consulting the local registers, it was found that the local rainfall from June to September had been 25·6 inches. The rainfall was also irregular. There was none between the 3rd and 20th August, but on that and the

succeeding day six inches fell, a considerable part of the town was flooded, and continued to be so for many days. The town is surrounded by excavations in which all kinds of refuse are thrown, and into these holes the rain drainage flows, and remains till it dries up. There was once a small cutting for carrying off part of the rain, but this had been silted up. A somewhat similar example was met with in the village of Barwala, with 3,062 people, who were found to be sickly and still suffering from fever. The village is about a mile from the Jumna Canal, but the people of another village nearer the canal were healthy. The Barwala village was surrounded by large excavations containing filthy water. No doubt in both cases the element of defective conservancy, and possibly of impure water, also acted injuriously, but each case presents a special problem in sanitary engineering, and it is very likely that they are merely type illustrations of the insanitary conditions which render Indian villages hotbeds of epidemics.

Some of Dr. Grant's remarks about the towns are of importance.

In the case of *Saharanpur* there is a municipal committee which keeps up a local and house inspection "in a most systematic manner," but this town of 59,194 inhabitants cannot be said to be drained. In the principal streets are rain-water drains, but none elsewhere. "The house drainage "flows directly outside into the street, and, where proper drains do not exist, a great nuisance is the "result, which must be prejudicial to health. . . . In some of the places visited the stench was "quite unbearable."

The death-rate in Saharanpur in 1883 was 39 per 1,000, and there were in it 136 deaths from cholera, and 1,258 from fever. Without desiring to give advice as to the kind of drainage to be provided, we may nevertheless state that, if surface drainage is to be adopted, all the drains should be impervious and of shallow section, and that a sufficiency of water should be provided to flush their impurities to an outlet. This is what Dr. Grant proposes.

The sanitary state of *Muzzaffarnagar* was considered satisfactory.

Meerut is far in advance of other towns in the circle in cleansing and in conservancy arrangements. The population of Meerut is 60,948. Its death-rate in 1883 was 23·48 per 1,000; it had only one death from cholera, but it lost 1,200 from fever.

Bulandshahr had a death-rate of 26·48 per 1,000 out of a population of 17,863. It had no death from cholera, but 334 from fever. This town was formerly a collection of kutcha huts. It has been "transformed . . . into one of the finest Native towns of its size in India. Handsome streets of "houses, constructed in the best style of Indian architecture, have been erected, and it has all been "done by the people themselves without any assistance from Government." This experience shows what can be done in the way of improvement in the hands of an enlightened magistrate like Mr. Growse. Some defective sanitary details are mentioned, which show that in all such improvements the public health aspect of them requires to be provided for while the architectural features are improved.

The habitations in another town, *Khurja*, were found in good condition, and similar architectural improvements had been introduced, but in this case also important sanitary details had been overlooked, but they were eventually attended to on Dr. Grant's recommendation.

The city of *Koil* "was fairly clean and the drainage good," but in every other essential of good sanitary condition there was deficiency, especially in arrangements for conservancy. The reporter adds, "the public latrines are the worst I have seen in any town," and as a consequence filth was everywhere visible.

In *Ferukhabad* and other towns in Mainpuri district, the drainage works appear to be of an injurious kind. There are "deep rectangular pucka side drains, for the most part arched over, but "leaving openings at intervals . . . extremely objectionable," as Dr. Grant remarks. It is scarcely too strong an expression to designate all drains of this type as added disease causes. They ought to be taken up and replaced by impervious shallow-sectioned surface-drains, such as are described and figured in our "Suggestions" (1882). Water would have to be provided for keeping them clean. We are glad to see that the magistrate was of the same opinion, and that the necessary improvements would be carried out when funds were available.

Mainpuri is commended for its handsome bathing tank, which is well kept and supplied with water.

About *Agra*, the principal remark made refers to its deficiency of good water. "The town of "Muttra was clean, and the drainage perfect." This is the record, but there must be something radically wrong about this place. Its population is 44,745, and its death-rate in 1883 was no less than 51·82 per 1,000, of which great rate 4·74 per 1,000 was due to cholera, and 21·80 per 1,000 to fevers. These losses were not those of a specially unhealthy year, because its previous five years' average death-rate had been no less than 64·85 per 1,000. Both rates are so high as to lead to doubts about the registration accuracy.

28. Under Section X., "General Remarks," Mr. Plank gives a brief account of inspecting work of inquiry and verification of vaccination returns, and regarding a proposed change of site for Hurdwar fair in lieu of the present unfavourable one, which, fortunately, has been partly washed away by floods. An account is also given of a proposed new site for a civil station at Kulpahar for Hamirpur. There are no points in the Report calling for remark, except the amount of chloride of sodium, 7·2 grains per gallon, in the water of the proposed civil station, supposed to compare favourably with the well waters of Agra and Allahabad, which contain from 33 to 40 grains per gallon. Comparisons of this kind are, however, inadmissible, on the obvious ground that if 7·2 grains of chloride of sodium per gallon indicates bad water, it cannot become less so by comparison with worse water. The rule to be observed in all such inquiries has been known in India for many years, and is given in the late Dr. Angus Smith's words in our "Suggestions" (1882). In any given water under

inquiry, the first step to be ascertained is the amount of chloride of sodium present (not in the well waters, all of which for the purpose must be set aside, but) in the natural pure waters of the district. That is, if the source under inquiry is a well, the amount of chloride of sodium in the water has to be compared with the corresponding amount in water obtained from a pure source in the vicinity (not of course a river). The two quantities having been thus obtained, the rule for ascertaining the sanitary condition of the proposed source of supply is as follows:—"Any amount of common salt "above the average of the district obtained in a well in a city or camp, or near habitations of men "or animals, is an almost certain proof of impure drainage."

It is not probable that the Agra and Allahabad well waters represent the condition of the district waters. What the analysis really shows is that both are unfit for use, and just in the proportion that chloride of sodium in the water of the Kulpahar site exceeds the amount of the district is that water open to suspicion.

29. The present Report would have to be pronounced deficient in sanitary information about disease causes were it not that these have been discussed in the Sanitary Commissioner's Reports year after year. The causes are known for all practical purposes. The fundamental of them are those connected with local topography, such as flatness of surface, without sufficient natural fall for drainage, the passage of great rivers and watercourses through it, and the presence of large areas of tarai country. If this was all the information at our disposal, the practical conclusion must be that an adequate execution of drainage operations to relieve the subsoil of superfluous water, together with improvements in agriculture and tree planting, were the required remedies against its decimating epidemics. But we know, besides, that large tracts of country have been rendered more than usually liable to fatal outbursts of fevers by irrigation works, without adequate provision of drainage. We know, further, that in this state of the country excess of rain acts with fatal effect wherever it falls, but more especially in districts under irrigation, and that for this the only remedy is facilitating subsoil water movement to an outlet. There is a probability also that the evils are augmented by careless use of irrigation water by the people.

It is, however, doubtful if all the high-fever rate should be attributed solely to causes of topographical and climatic origin, for it is very probable that the types and the mortality of these fevers are to a great extent determined by the local sanitary defects in towns, but especially in villages and village houses.

The practical result is that causes and effects re-act, and the stamina of the working population is reduced until they succumb in turn to the effect of their surroundings.

It is at this point that these sanitary questions become intimately connected, in epidemic countries especially, with social and economic questions, and with the functions of Government.

We have said enough in this and in preceding Memoranda to point out the remedies, which are no doubt beset with great difficulties, but the difficulties are no more than those which exist in all newly settled countries similarly situated. Some of the most unpromising examples of this class have been slowly but certainly improved by the continuous operation of human agency, a condition under which large areas of the earth's surface have been and can be alone made occupiable by human beings. In these provinces, as in the rest of India, improvements of this class are of another character altogether than those required for towns, and the whole work required for diminishing the liability of the people to epidemics would still have to be virtually done if every town in them were placed in the best attainable sanitary condition.

18th May 1885.

No. 7.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER of the CENTRAL PROVINCES for 1883.

1. In these provinces the office of Sanitary Commissioner has been united to that of Deputy Surgeon-General, and as this union involves frequent change of officers, it is scarcely possible for the Sanitary Commissioner to acquire sufficient knowledge of his district to enable him to be of use in the sanitary part of his office. In our Memorandum on the Report for 1882 we discussed the present state of the administration, and perhaps no better comment on its results could be made than is conveyed in the following opening passage of the section in this Report on "Inspections by the Sanitary "Commissioner, Central Provinces," in which the new succeeding officer says, "I cannot find any "notes of the inspections made by my predecessor in 1883, and I took charge too late in the year to "admit of my making any." Of course, this statement implies that for the entire year 1883 our knowledge of the sanitary state of these provinces, so far as this depended on the action of the Sanitary Commissioner, is a blank.

We must, however, take the information, such as it is, and try to make the best of it.

2. The population of 1883 is stated to be 8,817,185, while that of the preceding year was 8,802,040. The increase in 1883 is due to certain minor rearrangements in the districts, and is too small to affect the rates of the year for the whole population. But if taken by districts the additions and subtractions

of numbers would, in several of them, make a considerable difference, as is shown in the following abstract:—

Districts.	Population.	
	1882.	1883.
Murwara	205,307	167,716
Jubbulpore	481,299	525,890
Hoshangabad	488,737	488,594
Nimar	154,677	154,000
Burhanpur	75,446	77,123
Bilaspur	746,130	761,468

3. The births in 1883 amounted to 357,864, or 40·59 per 1,000, which in the light of home experience would be considered a somewhat high rate, although a little lower than that of the preceding two years. If there be no errors in the numbers registered within the registration districts, it is doubtful whether there may not be considerable errors in the population estimates. Eleven districts yielded birth-rates between 35 and 40 per 1,000, and one, Murwara, registered a rate of 54·29 per 1,000. We can form no opinion as to reasons for these rates, but the subject evidently needs to be inquired into, not only on this account, but because of its bearing on the death-rates, which present similar anomalies.

4. The death-rate of 1883 was 34·56 per 1,000, not an excessive rate when we take into account the cholera epidemic of that year. The town death-rate was 35·56 per 1,000, and the district rate was 34·48 per 1,000. But these rates varied in the towns between 14·52 and 78·38 per 1,000 and in the districts between 26·19 and 44·63 per 1,000.

We have already seen that Murwara district registered a birth-rate of 54·29 per 1,000, while its death-rate was 31·35 per 1,000, and then we find, as is shown in the preceding population abstract, that this district had a population, in 1883, of 167,716, while the number in 1882 was 205,307. Judged by the actual numbers of births and deaths registered, the general result is, no doubt, much better than in many other districts in India, but the details throw sufficient doubt on the registration to require some readjustment in the machinery.

5. The total deaths registered in the Central Provinces in 1883 were 304,763, under the following heads:—

Diseases.	Deaths.	Deaths per 1,000.
Cholera	16,235	1·84
Small-pox	4,696	0·53
Fevers	175,119	19·86
Bowel complaints	26,623	3·02
Injuries	4,593	0·52
Other causes	77,497	8·79
All causes	304,763	34·56

We shall next discuss the information about each of these death causes as it is given in the Report and statistical tables.

6. *Cholera.*—Deaths from cholera were registered in all the 20 districts of the Central Provinces, with two exceptions, Saugor and Sambalpur. The latter of these districts is the one which adjoins the cholera endemic area, in which Poori is situated. In Cuttack, Poori, and Balasore districts, cholera prevailed during every month of 1883, and there were 6,631 deaths registered from it, the death-rates being respectively 1·95, 1·26, and 2·12 per 1,000. The average death-rate was 1·88 per 1,000, while the rate for the whole of Bengal was 1·36 per 1,000.

There are 74 towns in the provinces, in 36 of which there were deaths from this epidemic. The country circles, with a population of 8,060,093, had 13,243 deaths, a rate equal to 1·64 per 1,000, and the town population of 757,092 yielded 2,992 deaths, or 3·95 per 1,000, but as half the towns escaped altogether, the rate of those which were attacked must have greatly exceeded this average. Indeed, so far as the attacked towns were concerned, the cholera of 1883 assumed the proportions of a great epidemic. In twelve towns the death-rate exceeded 10 per 1,000, and in one town, Narkher, in Nagpur district, with 7,061 people, 300 died of cholera, equal to a death-rate of 42·49 per 1,000. The town of Nagpur itself yielded a death-rate of 2·49 per 1,000, notwithstanding its excellent water-supply, showing that pure water was in this instance not a complete protection against epidemic intensity.

In the country districts there are 168 registration circles, 87 of which returned cholera deaths, but, notwithstanding the severity of the epidemic, no more than 1,405 villages were attacked, out of a total number of 28,427 in the provinces.

7. In our Memorandum on the Central Provinces Report for 1882, we adduced evidence to show that the provinces were not invaded from the endemic area of Lower Bengal, but from the south-

eastern end of the North-West Provinces, from which the epidemic spread in a broad belt from north to south till it entered the Berars. This was the main line of invasion. There was another invasion through Chota-Nagpur, also from north to south, but the march of cholera along this line was stayed at the centre of the provinces. The map attached to the present Report shows that the cholera of 1882, so far as the chief line of invasion was concerned, covered generally the same ground in 1883 as it occupied in the previous year, but that the second line from Chota-Nagpur had been broken across, and only showed its presence in the centre of the provinces. There appears to have been a neutral period during which no cholera deaths were registered, but when the time came the epidemic appeared generally over most of its old area.

8. The Sanitary Commissioner informs us that "the first reported case occurred on the 16th April, in Seoni district." It may be remarked, in passing, that this district was the earliest occupied in 1882. He then proceeds, "The number of deaths increased steadily in May (there having been only "a very few in April) till August, in which month it was largest, and from which time it rapidly "decreased, the deaths in October and November being comparatively few. The last reported case "occurred on the 17th November, in the Chanda district. . . . The disease did not follow "any particular direction, dying out in one part of the province and appearing in another, but it "increased and decreased at the same time over all the country affected." There was, however, a considerable difference in its severity within the same areas when compared with the epidemic of 1882, and, as the following monthly deaths show, it bore the impress of a resuscitated epidemic, and not of an epidemic invasion :—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
January	4	July	4,425
February	—	August	7,944
March	—	September	1,866
April	4	October	769
May	119	November	176
June	928	December	—

9. We have no means of comparing the monthly climatic elements with the cholera deaths. The mean annual rainfall for the whole province in 1883 was 53·59 inches, against a previous 17 years' average of 49·60 inches. In the rainy season the fall was above the mean, and it will be seen that after the September increase cholera rapidly subsided.

10. Compared with the death-rates from cholera during the last 10 years, that of 1883 took its place in the series as follows :—

Years.	Ratio per 1,000.	Years.	Ratio per 1,000.
1874	—	1879	3·77
1875	1·98	1880	0·04
1876	2·71	1881	1·04
1877	0·46	1882	1·36
1878	5·53	1883	1·84

The great rate of 1878 was related to the famine. The more recent ratios appear to show that a period of cholera increase is in progress.

11. The Report gives a statistical rather than a sanitary history of the cholera of 1883. There are, however, a few notes on the latter subject which may be introduced here. In Chanda district there were 980 deaths from cholera, equal to a rate of 1·83 per 1,000 of the population; these deaths took place in 89 population groups out of 1,634 in the district, or above 10 deaths per group. Two of them were inspected. In one the sanitation was "defective," in the other good, except "foul water round the wells." It seems as if more inspecting and executive work might have been recorded in this case.

In Chindwara district there are 1,350 villages, 155 of which yielded 2,354 cholera deaths, a ratio of 7·63 per 1,000 against a previous five years' average of 0·71 per 1,000 of the total population. The Civil Surgeon inspected 16 attacked villages in relation to this outbreak, and reported that "at the majority of these places the sanitation was very defective, especially at Pandhurna, and he "draws special attention to the practice that exists there, and at neighbouring places, of depositing "the excreta and dirty water in a deep hole filled with stones, close to the well which exists in nearly "every compound. At Lodhikera the state of the water in the river and its pollution by the people, "who use the bank as a latrine, and by the dyers, who throw their refuse into it, is particularly "dwelt upon."

Numbers of villages are reported on as being in an unsatisfactory sanitary condition; but in the cases not covered by the epidemic there was no cholera. It was the presence of the cholera which brought out the deadly consequences of sanitary neglect.

12. But, notwithstanding the presence of cholera, two fairs, Birman and Ramtek, were held and escaped the epidemic. "The Birman fair lasted from the 15th December to the 22nd January.

"The usual sanitary arrangements were in force, and there was not any especial sickness." The total attendance is said to have been 157,171, "the usual daily attendance 60,000, and the number "on the great bathing day being 132,000." There was, however, very little cholera in the neighbourhood where the fair was held.

In Nagpur district, where Ramtek fair was held, there were 4,857 deaths from cholera, and 462 villages out of 1,675 were attacked, so that the cholera was in the country in some force, and Ramtek circle yielded 134 deaths in 33 villages out of 176, and nevertheless the fair escaped the epidemic. "The sanitary arrangements were satisfactory. The area occupied by the visitors to the fair was "divided into blocks; constables and sweepers being attached to each." In this case there could be no doubt of the presence of the cholera epidemic in some force, that many population groups suffered, and that the fair under better sanitary arrangements escaped. This is only part of experience which extends to other fair sites.

13. The epidemic history of 1883 confirms that of all previous epidemics. It has shown that before there can be wide-spread epidemic mortality, there must be cholera, more or less, existing over a country, wherever it may come from. That, when cholera is present, all the population groups do not necessarily suffer. Some, or rather the large majority, escape in any given year, otherwise the country would be depopulated, but the escape of one year is no guarantee for another year's immunity. That local cholera outbreaks are intimately related to filth, damp, crowding, and bad water, but that by preventing these insanitary conditions at fairs, the people are protected from cholera which at the very time may be causing the loss of life in their homes.

14. *Small-pox.*—The following abstract shows the annual mortality from small-pox in these provinces since 1872:—

Years.	Small-pox Deaths.	Years.	Small-pox Deaths.
1873	9,936	1879	25,492
1874	17,696	1880	5,184
1875	26,226	1881	1,876
1876	3,819	1882	3,945
1877	2,768	1883	4,696
1878	16,151		

The figures show clearly the biennial periods of epidemic increase, but the last two years in the series would apparently show a lower degree of intensity of the disease than in the preceding periods of increase.

Small-pox prevailed extensively over the provinces in 1883, as is shown by the fact that deaths from it were returned from 139 out of 168 circles of registration, but as usually happens the whole mortality was yielded by only a small number of population groups, 1,973, namely, out of 28,427, following in this respect the course of all Indian epidemic diseases. Deaths were returned from 35 towns out of 74, some of them yielding only a single death. Out of the total 4,696 deaths forming the year's mortality, 380 were furnished by 757,092 town inhabitants, and the remainder by villages.

The monthly prevalence of small-pox in 1883 is shown in the next abstract.

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	358	July	579
February	384	August	357
March	613	September	195
April	607	October	90
May	630	November	115
June	581	December	187

This table shows the usual increase of small-pox during the hot months. The disease was very generally prevalent in all the registration districts during the year, but some of them escaped in certain months and others in other months. Only in one month, June, were deaths returned from all the districts, and a reference to the preceding abstract will show that June was one of the months of highest mortality.

The vaccination report for 1883 is not included in the year's sanitary Report.

15. *Fevers.*—Diseases classed under this designation constitute by far the most important death causes in the Central Provinces as they do all over India. As already stated, the mortality attributed to fevers amounted to 175,119 deaths, or a death rate of 19·86 per 1,000 for the whole population. To this rate the towns contributed 9,669 deaths, equal to a death-rate for their population of 21·77 per 1,000. The country districts yielded 165,450 deaths, or 20·53 per 1,000. Every one of the 168 registration circles yielded fever deaths. There is little doubt that every village suffered, for fever deaths were reported from 21,982 population groups out of 28,427 in the circles. All the 74 towns had deaths recorded from this cause.

The assigned fever death-rate for five years, 1878–82, was 20·61 per 1,000. The rate in 1882 was 17·31, and for 1883, as already stated, it was 19·86 per 1,000. But, as we shall presently see, not much reliance can be placed on the data.

16. The next abstract gives the monthly deaths under this head.

Months.	Fever Deaths.	Months.	Fever Deaths.
January - -	9,611	July - - -	14,390
February - -	8,896	August - - -	19,250
March - - -	10,159	September - -	20,549
April - - -	11,994	October - - -	19,208
May - - -	13,331	November - -	20,379
June - - -	10,779	December - -	16,573

All that this table shows is that the rainy and drying-up months yield the largest mortality from diseases classed as "fevers."

We shall next extract from the Report such information as it gives on the nature of these "fevers." This is not new, but it is important as another contribution to the subject which had "specially "engaged the attention of Dr. Browne, Civil Surgeon of Hoshangabad, during his sanitary inspec-"tions, and the Civil Surgeon of Chanda also inquired into the deaths reported as caused by fevers. "The result is given below. . . . . Of 77 deaths said to be due to fever inquired into by "Dr. Browne, 32 were apparently really caused by that disease and 45 by others, and of 150 deaths "registered as due to fever investigated by the Civil Surgeon, Chanda, 41 were found to have been "so caused, or only 41 per cent. in the one case and 27 per cent. in the other were actually due to "fever."

The Sanitary Commissioner gives an important table prepared by Dr. Browne to show what may be called the diagnostic error for the chief diseases. It is as follows:—

Total Deaths investigated.	Due to			
	Fevers.	Bowel Complaints.	Chest Affections.	Other Diseases.
365	128	76	61	100
Percentage - -	35·0	20·8	16·7	27·4

If these ratios could be accepted as general they would make an important difference in our estimate of relative death-rates, especially from fever. Thus in 1883, out of a total death-rate from all causes in these provinces of 34·56 per 1,000, which corresponds closely to the previous five years' rate of 34·43 per 1,000, the fever-rate was 19·86 per 1,000, showing that above 57 per cent. of the deaths in 1883 were assigned to fevers. A reference to the preceding table shows that, so far as could be arrived at by a very limited inquiry, the actual fever-rate ought to be 35 per cent. instead of 57 per cent. of the year's deaths, and this correction would reduce the registered fever mortality of 1883 from 175,119 to somewhere about 107,000. But even if we accept this correction as applicable to the whole registration area, we should still have an ascertained fever death-rate of about 12¼ per 1,000 to deal with, which is a third more than has been assigned under the present registration to other provinces of India.

The fever problem in the Central Provinces may be safely limited to this extent without in the least detracting from the paramount importance of these fevers, which the Sanitary Commissioner informs us are "no doubt chiefly intermittent and remittent, due to malaria," to the welfare of the people. The Sanitary Commissioner very properly suggests that this inquiry might be pursued with advantage by Civil Surgeons. These officers make extensive annual inspections, and they could render no greater service to the State than by hunting out the local malarial conditions at the same time and reporting them for removal to the executive authorities.

It follows that, making every deduction for errors in diagnosis, the abatement of fever causes constitutes the sanitary problem of the Central Provinces.

17. *Bowel Complaints.*—Not much need be said under this head, or in regard to the remainder of the disease history of 1883. Deaths from bowel complaints were reported from all the 168 circles of registration, and from 8,743 villages out of 28,427. It follows that these diseases (diarrhœa and dysentery mainly) were very generally prevalent, while their fatality was local. All the 74 towns, with three exceptions, returned deaths from them.

The town deaths were 2,150 in number, or 2·84 per 1,000 of the population, and the country deaths numbered 24,473, or 3·04 per 1,000.

The annual rate for the provinces was 3·02 per 1,000, against a previous five years' average rate of 2·91 per 1,000. The monthly deaths were as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January - - -	1,219	July - - -	2,913
February - -	1,060	August - - -	4,163
March - - -	1,422	September - -	4,066
April - - -	1,614	October - - -	2,763
May - - -	1,694	November - -	2,313
June - - -	1,615	December - -	1,781

By comparing the data in this table with those for cholera already given, it will be seen that July, August, and September were the months of maximum mortality for both diseases. The Report gives no information as to their local causes. As usually happens, the highest death-rate from bowel complaints was returned from Sambalpur district. It was 12 per 1,000, as against a previous five years' average of 11·33 per 1,000. It would appear as if these bowel complaints at Sambalpur were of local origin, because, notwithstanding the supposed relation of cholera to these affections, Sambalpur District had not a single death from cholera in 1883, and its previous five years' cholera rate had been only 1·42 per 1,000. Bad unwholesome drinking water may be one cause of prevalence of bowel diseases in this district, as the people appear to be infested with worms.

18. Among deaths from *injuries* were registered 655 suicides, 2,560 from wounds and accidents, and 1,378 deaths from wild beasts and snake-bite.

19. Under *all other causes* there were registered 77,497 deaths, or 25 per cent. of the whole mortality, and no account of their causes appears to be forthcoming.

20. *Sanitary Works (Civil).*—The items of expenditure under this head are not given separately, and the total outlay, above 14,000*l.*, was incurred in 19 towns. Of this sum about a third appears to have been spent on conservancy.

The chief improvement to which attention has been given in times past in the Central Provinces has been water supply. There were 172 new wells sunk in the course of the year, and a few wells were repaired. But the whole of this work is of small extent when compared with the number of villages.

Several towns have had their waterworks completed, but the distribution arrangements are still incomplete.

Jubbulpore waterworks were completed, and the water brought into the head-quarters town in July 1883, but the limited provision of hydrants had induced those living at a distance from them to use well water. The deficiency will, no doubt, be provided for, now that the water is there. It should be stated that Jubbulpore appears to furnish evidence of improving health under its sanitary administration. Thus, with a municipal population of 75,705, it had only one death from cholera during the severe epidemic of 1883, and its death-rate from all causes was 25·21 per 1,000, against a preceding five years' rate of 31·99 per 1,000. Its fever-rate of 9·85 per 1,000 is also low.

The water-supply of *Burhanpur* was being extended over the remaining third of the town, and the surface drainage had been improved in some parts of the town. Burhanpur has a population of 36,107, and, notwithstanding its water-supply, the quinquennial death-rate of 33·67 per 1,000 was raised in 1883 to 39·78 per 1,000, of which no less than 9·03 was due to cholera.

The waterworks at *Hinganghat* had been completed, so that now all the people get water from the reservoir, but the mortuary returns exhibit the same results as in Burhanpur. The five years' death-rate of Hinganghat had been 34·77 per 1,000, and it was raised in 1883 to 35·11 per 1,000, of which ratio 6·44 per 1,000 was due to cholera. The population of Hinganghat is 9,000.

The town of *Nagpur* has a population of 98,299. Its five years' death-rate had been 31·14 per 1,000, which was raised to 38·39 per 1,000 in 1883. Its cholera death-rate was 2·49 per 1,000, while the cholera death-rate for Nagpur district was 7·36, and the total district death-rate in 1883 was 44·63 per 1,000, against a preceding five years' rate of 33·66 per 1,000. For a number of years this populous town has enjoyed the benefits of an excellent water-supply distributed over it, and its sanitary condition has been in other respects undergoing improvement. It is not yet in the best practicable sanitary state, but, nevertheless, it can show good results when put in comparison with the district. The fever test is also favourable when applied in the same way. Nagpur town fever-rate was 4·39 per 1,000, against a fever-rate of 9·54 for the district. Part of the improvement in health is, no doubt, due to the waterworks, but the rates are still high for a town under active municipal government, and the result is that there is every reason to anticipate a still lower epidemic and general death-rate as sanitary work, especially cleansing and drainage, is persevered in.

21. Improved water-supply, together with minor improvements in surface work in a few localities, comprehend what is stated as the year's work. Nevertheless, with work of a number of years' duration in providing better water by new wells and waterworks, there are epidemics of cholera. It is not that better water has not been an advantage, but the purest attainable water-supply is only a protection against epidemics due to the bad water it had taken the place of. If other sanitary defects, especially defects in cleanliness, have been overlooked, the deadliest of local causes of cholera will have been passed by without notice, and that such disease causes exist is perfectly well known.

22. In the present Report are given very brief inspection notes by Civil Surgeons, and in several of them attention is called to various sanitary defects, several of which we have already referred to, in their relation to cholera. Thus in *Hoshungabad* district the Civil Surgeon reports that "in *Sohagpur*" conservancy was not well attended to, and the latrine accommodation not sufficient.

At *Harda* sanitation was fairly attended to, but the private latrines were bad. At *Seoni* and *Malwa*, while the conservancy was good, the drainage was "bad." In 19 villages "the wells were not cleaned nor "their mouths protected by a coping." Of 15 villages in Betul four were found dirty and 11 clean. The inspection notes show that a similar mingling of the apparently clean with the visibly dirty is a not unfrequent occurrence.

At *Burhanpur* "the public sanitation was good, but that of the "private houses and compounds "bad."

"In *Bilaspur* itself drainage is bad and conservancy defective. "Fourteen villages are reported, the "sanitary state being in most, unsatisfactory."

In *Mandla* "the Civil Surgeon inspected 33 villages and found them evidently swept and cleaned "for his inspection, but fears only on that account."

Sixty villages were inspected in Narsinghpur. "The Civil Surgeon does not consider it necessary "to give detailed accounts of their state, as it was the insanitary condition in which villages are "usually found."

23. The Native Superintendents and Vaccinators also reported on a very large number of villages. It is considered not to be necessary to enter into details. But the Sanitary Commissioner gives the following as a summary of the different Reports:—

"(1.) Uncleanly state of the interior of the village and its immediate vicinity.
"(2.) No particular place being set apart as a latrine, and so the ground all about close to the "houses being used as such.
"(3.) The housing of large numbers of cattle in the interior of the village.
"(4.) The badly protected state of most wells' mouths, and the absence of a drain to carry off "dirty water from round the well, both causes leading to the pollution of the water-"supply.
"(5.) The defilement of the banks and beds of rivers, the water of which is used for drinking "purposes.
"(6.) Defective drainage."

24. It will be observed that this summary reproduces the results of previous years' village inspections in these provinces. There is nothing new, only the previously detailed sanitary defects are still much as they were. In a previous Memorandum we stated that the defects carried with them their own required remedies. To this the local authorities have replied (as we learn from the Resolution of the Government of India on the present year's Report), "that the difficulties to be "encountered in attempting to deal with these disease causes are really very great, and that, in fact, "there is no more difficult problem than to get the villagers to recognize the insanitary and "unwholesome condition of their surroundings, to revolutionize their daily habits and practices, and "to supply the very considerable sums of money which would be needed to remove even any one of "the causes to which disease is attributable."

25. It is fully admitted that the subject is beset with difficulties, but we feel bound to concur with the following comment of the Government of India on this statement of them by the Local Government:—"There is no doubt," they say, "much truth in these remarks, but it is equally true that if "district officers really interest themselves in the matter, a great deal can be done by their influence "and judicious guidance to improve the surface drainage of villages, to set apart and preserve in "good order tanks or wells for providing pure water to the villages, to keep clean the compounds "and surroundings of houses, and to provide accommodation for keeping cattle as well as for latrine "purposes at a distance from human habitations. It is of the highest importance that the improve-"ment of the conditions under which the people live should be regarded as most intimately "connected with their happiness and prosperity, and that it should not be set aside as a thing which "is practically impossible."

It appears to us to be unnecessary to add anything to this wise judgment on the whole case by the Supreme Government. It involves no outlay for great sanitary works. The people themselves could do nearly the whole of it. Cleansing and keeping clean, with a little spade labour now and then to drain the surface, and very ordinary care in protecting water sources would soon tell on the sanitary state of villages, if the local officers would include these matters as amongst those on which their influence might be brought to bear.

This may may be said to be the practical result of the present year's Report.

26. Before concluding this Memorandum it is necessary to introduce a correction of some remarks made by us in our Memorandum on the Report of 1882, which involved a serious charge of neglect on the part of Civil Surgeons in not having referred in their inspections to the Village Sanitary Code of 1879. The statement was quoted from the Report, but it now appears that from some mistake the Code had not reached the village authorities or the inspecting officers.

1st April 1885.

No. 8.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for the Hyderabad Assigned Districts for 1883.

1. The population of Hyderabad Assigned Districts under registration in 1883 consisted of—

Males	1,358,275
Females	1,271,743
Total	2,630,018

These numbers are taken from the census enumeration of 1881, and would, if accurate, be approximately correct in 1883.

2. The birth and death-rates based on this population were distributed between rural registration circles and towns in the following ratios during the year under review :—

Ratio per 1,000 of Population.					
Rural Circles.		Towns.		Total.	
Births.	Deaths.	Births.	Deaths.	Births.	Deaths.
40·6	51·7	37·4	50·4	40·0	51·4

With these data before us we must hope that the population used as the basis of comparison was much below the truth in 1881, or else that an unexpected increase of population had taken place in the two intervening years. The birth-rate of 4 per cent. for the districts as a whole, rising to 43·2 per 1,000 in Buldana district, and to 51·9 per 1,000 in one of the towns, cannot be accepted without such an amount of caution as to throw doubts on the registration, or on the basis on which the ratios are calculated. We sincerely hope that this latter supposition may be a correct one, otherwise we should have these districts presenting the enormous death-rate of 51·4 per 1,000, taken over the entire population, including in it a death-rate of 55·2 per 1,000 for Amraoti rural circles, 57 for Akola, and 66·1 for Ellichpur.

3. It might be supposed that the town enumerations were more accurate than those of the country districts, but if we concede this as a possibility what can be said about these town death-rates? A list of 29 towns is given in the Report, only five of which had death-rates under 4 per cent. in 1883; all the others exceeded this high rate, and in these the death ratios ranged between 4 per cent and 77·3 per 1,000. The town rates as a whole are the ratios due to a great pestilence, and yet sanitary work has been in progress for years. Upon the whole, while admitting that 1883 may have been an unhealthy year, we should be unwilling to accept, without further and special inquiry, either the accuracy of the mortuary record or the numbers on which the death-rates are calculated.

4. The registered births in 1883 were 105,921, and the deaths 135,081. The deaths exceeded the births by 29,160, showing not an increase in consequence of the high birth-rate, but a decrease of 11 per 1,000 of the registered population. This result, when taken with those already stated, appears to justify a recommendation that this entire subject of population and registration should be inquired into.

This is not the first time that these excessive rates have been brought under review. In 1878 the famine and scarcity year, a death-rate of 81·5 per 1,000 was reported. It was, we believe, found on this occasion that the deaths were registered, but there was no account of any fresh enumeration of the people where this great loss of life took place.

5. It will be seen that too much reliance cannot be placed on the death-rates, as means of comparison, but the actual numbers of deaths are probably more correct, and may be used for such a comparison as the following :—

Returns of 1882-83 in relation to the deaths.

Seasons.	Deaths.		Mean Temperature.		Rainfall.	
	1882.	1883.	1882.	1883.	1882.	1883.
			°	°	Inches.	Inches.
1st quarter	15,730	16,969	19·0	19·0	0·92	0·67
2nd "	15,057	24,813	19·4	22·2	8·73	10·86
3rd "	26,759	67,180	19·6	19·5	18·80	40·87
4th "	19,538	26,119	18·2	17·4	6·23	2·25

The "mean temperature" in this table is probably the monthly or quarterly range, but it is useless. There is, however, a decided relation between the deaths registered and the amount of rain.

The following data, showing the facts of 12 years, are given by the Commissioner of the Assigned Districts, but it will be observed that the death ratios are used in the comparison :—

Years.	Rainfall.	Death-rate per 1,000.	Years.	Rainfall.	Death-rate per 1,000.
	Inches.			Inches.	
1872	38·35	37·1	1878	43·77	81·5
1873	25·44	22·8	1879	38·22	23·7
1874	29·98	27·9	1880	22·96	23·6
1875	34·13	40·3	1881	34·67	29·1
1876	24·70	31·9	1882	29·49	29·4
1877	26·74	29·1	1883	53·14	51·3

It is necessary, in dealing with data of this class, to call attention to such facts as the following:— In 1878, a fall of 43·77 inches of rain was attended by a death-rate of 31·5 per 1,000; while the addition of some 10 inches of rain in 1883 was attended by a reduction of 30 per 1,000 in the death-rate. It would hence appear that some other concomitant cause operates in raising the mortality. In 1878 this cause was famine, and we shall have now to inquire, so far as the facts in the Report may enable us to do so, into the causes which led to the large increase of mortality in these provinces in 1883, beginning with the disease history of the year.

6. The following abstract gives the assigned death causes in 1883:—

Diseases.	Deaths.	Deaths per 1,000.
Cholera	27,897	10·6
Small-pox	3,853	1·5
Fevers	53,593	20·3
Bowel complaints	19,044	7·2
Injuries	1,073	0·4
All other causes	29,621	11·3
All causes	135,081	51·3

This abstract shows that a twenty-fifth part of the people of these provinces was carried off by epidemic diseases in 1883. And the increase in epidemic mortality in this year, when compared with the preceding five years' rates, stood as follows:—

DEATHS from EPIDEMIC DISEASES.

Diseases.	Death-rate per 1,000.	
	1883.	Five Years' Average.
Cholera	10·6	3·2
Small-pox	1·5	0·5
Fevers	20·3	17·5
Bowel complaints	7·2	5·3
Total	39·6	26·5

The epidemic death-rate of 1883 was thus 13 per 1,000 in excess of the preceding five years' average, while it exceeded the corresponding rate of 1882, which was 21·6 per 1,000 by 18 per 1,000. The cholera death-rate of 1882 was 1·4 per 1,000, and the fever-rate was 15 per 1,000, while the small-pox rate was ·1 per 1,000; and the conclusion is that there was a great outburst of epidemic diseases in 1883, to which the very large augmentation of mortality was due.

7. We shall next discuss the disease history of 1883, beginning with cholera, and its previous statistical history, which has been as follows:—

ANNUAL CHOLERA DEATHS, 1868 to 1883.

Years.	Registered Cholera Deaths.	Rainfall.	Years.	Registered Cholera Deaths.	Rainfall.
		Inches.			Inches.
1868	5,447	—	1876	2,683	24·70
1869	10,947	29·23	1877	842	26·74
1870	904	37·63	1878	34,306	43·77
1871	581	19·12	1879	223	38·22
1872	1,578	38·35	1880	1	22·96
1873	—	25·44	1881	3,404	24·67
1874	2	29·96	1882	3,573	39·49
1875	22,465	34·13	1883	27,897	53·14

This 16 years' table gives the law of epidemic cholera in these districts, and it shows that this pestilence attacks the population in the manner of violent outbursts with periods of quiescence. We

have added the annual rainfall, to trace, if possible, any relation which may exist between the amount of rain and the deaths from cholera, but there does not appear to be any such relation, except that in years when the rainfall was heaviest the cholera deaths were most numerous. There are four such years in the table, 1869, 1875, 1878, and 1883, out of 15 for which the rainfalls are given. In these four years the aggregate rainfall was under 33 per cent. of the total rainfall of the whole period, that is, about a third of the rain fell in four-fifteenths of the time, but the cholera deaths in these four years amounted to 87·7 per cent. of the total cholera mortality of the 15 years. This same result has followed comparisons between the total years' rain and the total cholera mortality in the Punjab, where the facts have been ascertained, and any influence exercised by rain on cholera must be sought in the rain distribution when compared with the monthly cholera deaths.

The following abstract shows the facts under this head:—

Months.	Cholera Deaths, Mean of 15 Years.	Cholera Deaths, 1883.	Rainfall, 1883.
			Inches.
January	25·1	30	0·01
February		1	—
March		—	0·05
April	127·7	14	0·04
May	274·8	77	0·24
June	767·9	1,265	10·93
July	1,703·2	20,667	13·20
August	1,825·8	14,534	9·18
September	752·4	1,160	11·90
October	195·0	119	7·66
November	69·5	26	0·28
December	38·1	15	—

This table shows that the monthly incidence of cholera in these districts is pretty much the same in all years. The months of maximum mortality are July and August, but the rainfall of the year covers five months, June to October included. At first sight the monthly rainfall appears to coincide with the monthly mortality, but the coincidence is only partial, and there is no doubt that the fall of 19¼ inches of rain in September and October is attended by a rapid decline and disappearance of cholera. In an undrained country rainfall accumulates as the rainy season progresses, and hence the observed increase of malarial diseases, but in districts where rain cleanses surfaces and tanks, and replenishes wells, continued rain diminishes liability to cholera. This is of course a general statement, for there may be local examples in which rainfall is injurious, even in cholera times; but, taking the evidence furnished by the data as a whole, we should scarcely be justified in adopting the conclusion that in the Hyderabad Assigned Districts increase of rain causes increase of mortality from cholera.

8. We next shall give a brief account of the cholera epidemic of 1883. In the preceding table it is shown that there were 30 deaths from cholera in January, and only one in February of that year. The January deaths were part of the epidemic of 1882, which began in July, and declined to 100 deaths in December, which were followed next month by the 30 deaths in the table. The real epidemic, as the table shows, began with 14 deaths in April, and ended with 16 in December, so that this epidemic, like the same year's epidemic in the Central Provinces, was completed or nearly so within the year 1883. The disease followed a similar course over the area of the Central Provinces and Berar, and in neither area did it bear the marks of an invading epidemic. Cholera was dormant in both sets of provinces, and it followed the history of a resuscitated epidemic in both areas. The invading cholera moved southward in 1882, from Bengal and the North-West Provinces. The following account of the cholera of 1883 is given by the Sanitary Commissioner:—"The cholera of "1883 commenced in the month of April, in the Basim and Amraoti districts. The disease progressed "but slowly during May, being confined entirely to these districts, but in June, favoured by the "approach of the south-west monsoon, the pestilence developed greater activity, and prevailed with "more or less intensity in every district of the province. The first report of cholera was received "from the Basim district, where it broke out on the 16th April, in the village of Wanegaon, in "Unmarked registration circle, situated in the extreme south of the province. On the 24th April "the disease appeared in Amraoti circle of the Amraoti district, almost at the other extremity of the "province, about 84 miles distant to the north."

On receipt of this intelligence the Sanitary Commissioner issued a circular to district officers and Civil Surgeons, warning them of the probable outbreak of cholera, and also warning them to pay strict attention "to cleanliness and general conservancy, and to keeping the drinking "water-supply pure and free from pollution," and suggesting that the attention of municipal committees and of town and village authorities should be called to the subject. "Up to about the "end of May the disease," he adds, "made little advance, being confined entirely to the Basim "and Amraoti districts, but with the first fall of rain in June it began rapidly to develope, "and soon spread over the whole province." We have already seen that there were 77 deaths in May, with less than a quarter of an inch of rainfall, but in June there was a fall of 10·93 inches, and the cholera deaths mounted up to 1,265. Was this a mere coincidence, or did it mark distinct causation? We have no means of deciding, because there are other atmospheric agencies, which in all probability affected the result, such, for example, as temperature suddenly lowered (a known

predisposing cause of cholera in a country where it is already present), and increased moisture of the air with reduction of temperature. Apart from questions of subsoil damp, increase of putrescence in neglected unclean houses, compounds, and villages, and temporary washing of filth into water sources, it is not unlikely that these climatic elements, which are personal in their action, may have aided in developing the epidemic, which, as the following facts show, was one of great intensity and general prevalence.

9. Cholera prevailed over all the six districts of Berar. These districts are divided into 145 registration circles, and cholera was present in 142 of them. They contain 5,564 villages, and nevertheless, true to the law of partial distribution in time and area, the whole of the deaths in 1883 were returned from 1838 villages only. There are 11 towns, with a census population of 138,378, which returned 1,581 deaths from cholera, or 11·4 per 1,000 of the estimated population, a higher rate than that returned for the rural circles, which was 10·6 per 1,000. The comparative prevalence of the epidemic in the districts is shown in the following table:—

Districts.	Total Number of Villages.	Villages attacked by Cholera.		Average Number of Deaths in each affected Village.		District Death-rates.	
		1882.	1883.	1882.	1883.	1882.	1883.
Amraoti	1,047	144	408	9·7	15·5	2·4	21·0
Ellichpur	474	18	265	5·7	19·4	·4	19·0
Wun	1,260	106	251	7·1	11·4	1·9	7·2
Basim	945	29	305	6·7	15·6	·5	13·3
Akola	964	130	373	6·3	15·5	1·4	9·7
Buldana	874	54	236	5·1	12·4	·6	6·7
Total	5,564	481	1,838	7·4	15·2	1·4	10·6

The population groups affected in 1883 were nearly fourfold of those which suffered during the preceding year, while the deaths exceeded a sevenfold proportion in 1883, so that we have another illustration of the influence of epidemic intensity, not only in covering a larger area, but in the greatly increased proportion of deaths in the area covered. The increase of area to the increase of deaths was as four to seven nearly. Similar facts are common enough, and no theoretical etiology of cholera can afford any help towards the understanding of them. They must be accepted at present simply as facts.

10. In a preceding table we have shown how cholera in these provinces occurs in outbursts in particular years, and the present Report contains analogous facts for the districts, which show how very intense the epidemic must have been, in some regions of Berar when compared with others, in 1883, and how much more severe it was in that year than during the preceding five years' period. The facts are contained in the following abstract:—

Districts.	Cholera Deaths per 1,000 of Population.	
	1883.	Previous 5 Years' Average.
Amraoti	21·0	2·3
Ellichpur	19·0	1·0
Wun	7·3	3·0
Basim	13·3	6·9
Akola	9·7	2·4
Buldana	6·7	4·1
Total	10·6	3·2

This abstract shows the relative intensity of this epidemic in each district when compared with the same element during five preceding years. It will be observed that there is no relation between the ratios. The lowest five years' ratio of 1 per 1,000 in Ellichpur is followed in 1883 by a 19-fold mortality. As the local insanitary conditions have doubtless remained very much the same, we are shut up to the conclusion that the great death-rates shown in the table were due to greater intensity in particular regions of the epidemic conditions apart from everything else, or that the liability to death from cholera had increased in some areas more than in others.

11. We have endeavoured to discuss the facts as a contribution to the general history of cholera; but, practically, they also show that, however much insanitary conditions may count for in augmenting liability to attacks of cholera, the warning precautions adopted by the authorities were quite inadequate to protect the people, because the time was past when they could have been of use. If we wish to diminish or remove the sanitary defects in cleansing, draining, water-supply,

unwholesome dwellings, &c., which are known to add so much to the cholera death-rate, so that life may be saved two, three, or five years hence, we must carry out the work now and not then. There are two divisions of sanitary work which must be attended to. First, the work has to be done, and when it is once done great care must be exercised to prevent matters returning to their previous condition. When a powder magazine is on fire it is not the safest time to remove the powder, even if it were possible to do it. The safest thing then is to run away.

12. The earliest cases of the Berar epidemic were considered on the spot to have been due to importation from Poona. A woman arrived at Amraoti district from one of the Poona districts, and lodged on her arrival in a "room" used as a cattle shed. She had a choleraic attack, from which she recovered; but as other cases followed, not in the same house, which was occupied by 16 people but in other houses, this woman was blamed for the importation of cholera, which subsequent inquiry proved had not appeared in the Poona district, from whence she came, until seven days after her arrival at Amraoti. The place where the first real cholera case occurred was Hamalpura, a recently formed suburb of Amraoti. Newness, it would appear, is no protection against sanitary pollution of sites, for referring to the man first attacked, the Civil Surgeon says, "If filth and non-sanitary "conditions produced cholera in him, then he must have met these conditions in Hamalpura. This "place was very dirty, each row of huts having its row of animals alternating with it, the ground "saturated with the excretion of cattle," and yet this place, where "seven cases of cholera suddenly "appeared, is described as a perfect city of Hygeia, compared with Bulgaon itself."

13. The following example taken from Wun district shows the sanitary state of an attacked locality. "In the village of Digras cholera broke out on the 27th (June), where, out of 17 seizures, "9 died. This village was also found in a very insanitary state by the Civil Surgeon, owing to the "number of putrid carcases of cattle lying about. Mr. Chamarette states that the mortality amongst "the cattle was "terrific," and that the village dhers, whose duty it is to remove dead animals from "villages, could not do all the work. It is in such matters that the people of India will not help "themselves. Caste prejudice forbids a Hindu to touch a dead animal, and sooner than help to "remove or bury a decomposing carcase, he will let it rot on his doorstep, or in the stream from "which he may draw his water-supply, until the low caste dher has the time or inclination to remove "it." In this case the state of the village was not reported to the district officers as it ought to have been.

14. We may add the following case from Buldana district, in Deodaba village. Fifteen cases were attacked on the 28th June, three of which proved fatal the same evening. "The village "consists of about 300 thatched and dhaba huts, with a population of about 1,500, and is situated "on low ground, as it is now surrounded by a swamp. All the way to it from the railway station "I had to walk ankle deep in mud. The streets were worse, and a stream was flowing by the "entrance way through a portion of the village. The sanitary state of the village is bad. Cattle "are housed in the village, and house refuse is deposited just outside. The water-supply was "abundant, being drawn from 25 wells. Several of these, however, were submerged during the "late heavy rain, and several admitted surface drainage, not being walled."

15. These examples, taken from different areas of the Assigned Districts, may be adopted as illustrations of the sanitary state, generally at least, of attacked groups of population, and we cannot do better in concluding this history of cholera than to quote the result of sanitary precautions adopted at Deulgaon fair in Buldana. Cholera appeared in this district in June, and yielded the following monthly deaths:—

Months.	Cholera Deaths.	Months.	Cholera Deaths.
June	4	September	250
July	559	October	47
August	2,060	November	11

The fair was to be held at the beginning of October, and in the then known facts about the epidemic the Assistant Commissioner urged that the fair should be prohibited. It was, however, conceived that as the epidemic was declining in the district there would be no risk if suitable measures of protection were enforced, such as "cleansing and keeping clean the area occupied by the people "and their cattle, providing latrines, providing and protecting wholesome water sources, and pre-"venting overcrowding of both men and cattle." This course, advised by the Sanitary Commissioner, was adopted, and the results are recorded by him in the following words:—"The fair was duly held, "sanitary precautions and arrangements for the treatment of the sick were instituted, and the "gathering passed off without the occurrence of any unusual sickness."

In the face of the cholera history we have given for these provinces, this Deulgaon fair partook of the nature of an experiment to show what dependence could be placed on sanitary precautions for protecting human life during a very intense cholera epidemic, and the result was, that while the people died in their villages in the absence of suitable sanitary care, they escaped at the fair where precautions adapted to the circumstances were taken. Surely, it is not necessary to point out the moral.

16. *Small-pox.*—Deaths from small-pox were registered in all the districts and towns of the Berars. In the former there were 3,123 deaths, and in the towns 730. The district death-rate was 1·3, and the town rate was fourfold, or 5·3 per 1,000. The rate for the province was 1·5 per 1,000, or threefold the previous five years' ratio, which was ·5 per 1,000. The year 1883 was hence an epidemic year. The disease was spread generally over the districts, and deaths were registered from it in 117 out of 145 circles of registration, but, as usually happens with epidemics, the whole year's mortality was furnished by a small number of population groups,—only from 608 villages out of a total of 5,564. Every month yielded small-pox deaths, as is shown by the following abstract. The mortality in January shows that the epidemic of 1883 began in the preceding year, but it had apparently come to an end in 1883. The largest mortality was due to the hottest months.

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	386	July	174
February	465	August	68
March	782	September	33
April	861	October	13
May	520	November	16
June	319	December	16

17. The local sanitary conditions which prevailed in affected villages were, no doubt, the same as those already described, and have remained so year after year; but the present Report furnishes evidence of diminution of small-pox mortality, co-existing with better vaccination. This fact is shown in the next abstract.

Years.	Small-pox Deaths per 1,000.	Ratio per 1,000 successfully vaccinated.	Years.	Small-pox Deaths per 1,000.	Ratio per 1,000 successfully vaccinated.
1868	1·9	4·3	1876	0·2	31·1
1869	3·6	3·2	1877	2·9	38·0
1870	·6	7·9	1878	2·7	22·3
1871	0·2	13·0	1879	0·03	29·3
1872	3·8	16·2	1880	0·02	33·9
1873	3·3	14·5	1881	0·08	32·5
1874	0·5	21·0	1882	0·1	38·0
1875	0·4	24·0	1883	1·5	30·3
8 years' aggregate	14·8	104·1	8 years' aggregate	7·53	255·4

This table exhibits several important facts in the local history of small-pox. It shows the distinctly epidemic nature of the disease, and that it recurs with greatly augmented mortality at fixed periods. In 1870 the first period of quiescence began, and it lasted over 1871, to be followed in the next two years by an outbreak during which the deaths were above ninefold more numerous than in the two previous years. This outburst led to three quiescent years, to be followed in 1877–78 by two years of increase and a fivefold mortality. Then came, not two nor three, but four years of quiescence, followed in 1883 by what appears to have been the beginning of another epidemic augmentation. But alongside this history of small-pox the table contains a record of vaccination work, from which it appears that in 16 years rather more than a third of the population (359·5 per 1,000) had been successfully vaccinated, while 22·33 per 1,000 had died of small-pox. The table divides these 16 years into two eight-years periods, in the first of which the vaccinations present an aggregate of 104·1 per 1,000, and the small-pox deaths a ratio of 14·8 per 1,000. But during the second eight years the successful vaccinations had risen to 255·4 per 1,000, while the small-pox deaths had fallen to 7·53 per 1,000, or to one-half. The table also shows that the periods of increase are stationary at two years, but that the periods of quiescence have lengthened, and that, moreover, the death-rates of both periods have been declining. It follows that the mortality from small-pox is normally diminishing in Berar, or else that the vaccination work is telling favourably on the death-rate. To arrive at either conclusion, we should require to know the births, deaths from small-pox, their ages, and the ages of vaccination. The birth element, as we have seen, is at present a doubtful one. If we take it at 40 per 1,000, not one of the highest estimates, we should have for the 16 years an aggregate of 640 per 1,000, or double the whole vaccinations at all ages for the period. But, on the other hand, the vaccination ratios of 33, 32, 38 per 1,000 during the later years came much closer to the 40 per 1,000 birth-rate, if they do not even cover it, were it correctly known.

On the whole, then, the conclusion appears to be warranted that successful vaccination in Berar has done two things; it has diminished small-pox mortality, and by diminishing the number of susceptible subjects it has modified and lessened the severity of epidemic periods on their recurrence.

18. This experience justifies a strong recommendation that the vaccination service should be more specially directed to securing the successful vaccination of infants.

The general susceptibility to epidemics in these districts, which is so high at present, will be also lowered when sanitary work advances. As affording a clue to the localization of both classes of preventive service we shall here give the district small-pox mortality for 16 years :—

Districts.	Small-pox Deaths per 1,000.	
	Mean of 15 Years.	1883.
Amraoti	1·46	2·3
Ellichpur	1·00	1·9
Wun	0·94	0·3
Basim	1·35	0·5
Akola	1·46	1·4
Buldana	1·63	1·9
Means	1·39	1·5

19. *Fevers.*—Deaths registered under this head in 1883 numbered 53,593, of which 27,880 were deaths of males and 25,713 of females. The death-rate was 20·3 per 1,000, against a previous five years' average ratio of 17·5 per 1,000.

Fever mortality was very generally distributed during the year. All the registration circles, 145 in number, returned deaths under this head, and out of 5,564 villages fever deaths were returned from 4,019. Each of the 11 towns in the province returned fever deaths, yielding a general ratio of 17·3 per 1,000, while the rural circles had a rate of 20·5 per 1,000. The following ratios for districts show that the increase of fever in 1883 was general throughout the province :—

Districts.	Fever Deaths per 1,000.	
	1883.	Five Years' Average.
Amraoti	20·7	17·9
Ellichpur	21·6	18·8
Wun	26·9	21·4
Basim	12·2	11·9
Akola	23·4	19·4
Buldana	15·8	14·4

The increase of fever mortality in 1883 was greater over some areas than over others, but whatever was the cause of the increase it was active over all the districts. The fever death-rate during 15 years had averaged for these districts 14 per 1,000, which rate was exceeded by the rate of 1883 by 6·3 per 1,000. Two facts have therefore to be considered, and, if possible, accounted for. First, the fever mortality itself; and secondly, the cause or causes of the rise of death-rates in 1883.

20. We have already dealt with the relation of rainfall to the general death-rates of Berar, and as fevers constitute so large an item in the general rate, it is reasonable to suppose that the amount of rain has an influence on the amount of fever. There are three ways in which the prevalence of fever may come under the influence of the amount of rain in an undrained and imperfectly cultivated country. There is, first, the effect of the annual fall, that is, of the total amount of rain; next, the effect of its distribution in time, namely, its daily or monthly amount; and next, its local accumulation as influenced by the local topography and natural drainage areas. We shall see what information the present Report yields under each of these heads; and first as regards the total annual rainfall. The relation of this factor to fevers has been as follows :—

Years.	Total Rainfall.	Fever Deaths per 1,000.	Years.	Total Rainfall.	Fever Deaths per 1,000.
	Inches.			Inches.	
1868	—	5·2	1876	24·70	18·2
1869	29·23	6·2	1877	26·74	15·8
1870	37·63	10·5	1878	43·77	38·9
1871	19·12	8·3	1879	38·22	14·8
1872	38·35	14·5	1880	22·96	14·2
1873	25·44	8·8	1881	34·67	15·8
1874	29·98	12·2	1882	39·49	15·0
1875	34·18	11·9	1883	53·14	20·3

It is quite clear that, whatever may be said about the annual rainfall as a fever cause, the fever ratios of the earlier years in this table are not to be relied on. Again, the great fever rate of 1878, although co-existing with a high rainfall, was mostly due to famine fever. Leaving out that year it is true that the fever-rate of 1883, which would thus become the highest in the series, co-existed with the highest annual rainfall of the whole series, but then comes in the objection we have already urged

against the reliability of the data upon which the death-rates have been calculated. Taking the cas simply as it stands, the evidence appears not to be sufficient to establish a definite relation betwee the total year's rainfall in these provinces and the calculated fever death-rates.

21. As regards rain distribution, the information is not as full as might have been desired. An average of the monthly fall at 23 stations is given, to admit of comparison with the monthly fever deaths during 1883 in the next abstract.

Months.	Fever Deaths.	Average Rainfall.
January	3,192	0·01
February	2,693	—
March	2,979	0·05
April	4,051	0·04
May	4,919	0·24
June	3,410	10·93
July	5,418	13·2
August	7,278	9·1
September	5,853	11·90
October	4,971	7·66
November	5,008	0·28
December	3,811	—

These data show a large increase of fever mortality following heavy rain, but it is not unlikely that if the local rainfalls could have been compared with the local monthly fever-deaths the connexion of the two events would have been more clearly shown than it is in this average table.

22. We have not the means therefore of connecting local monthly rainfall with the topography and fever prevalence. The only data at our disposal for this purpose are included in the next abstract, which shows the rainfall compared with the fever mortality in each of the districts on a five years' average.

Districts.	Fever Deaths per 1,000, on a Five Years' Average.	Average of Five Years' Rainfall.
Amraoti	17·9	34·92
Ellichpur	18·3	35·62
Wun	21·4	41·90
Basim	11·9	39·10
Akola	19·4	38·72
Buldana	14·4	34·55

The relation between the two sets of figures is not sufficiently obvious to point to any law of fever causation, although in Wun district we have the highest average fever-rate co-existing with the highest average rainfall. It is worthy of remark, however, that the Basim rate, which is the lowest, 11·9 per 1,000, is connected with a rainfall of only 2·80 inches less than the Wun rate.

23. The object of this discussion has been to obtain as clear an account of the facts as possible, and the result appears to be that the fever mortality in these districts is due to other factors besides the absolute amount of rain; and while we admit fully the influence of wet years on the prevalence of fever, we are very desirous that the grave practical error should be avoided of treating the rainfall as an ultimate cause of fever, and so being in danger of neglecting those local causes which alone admit of being dealt with by sanitary measures. We have little doubt that if the towns and villages were placed in a thoroughly wholesome condition there would be a great reduction in the district fever death-rates, but looking at the relation between these rates and the district rainfall, it seems not at all unlikely that the local topography exerts a not unimportant influence on the amount of fever. In the absence of knowledge as to the configuration and drainage of the districts, this is all we should be justified in saying.

24. *Bowel complaints.*—The registration of diseases under this head is of so very uncertain a character that only a few remarks are called for. Deaths from bowel complaints were registered in 143 out of 145 circles, and they appear to have been generally prevalent. They were returned from 2,118 villages out of 5,564 in the province, and every month yielded deaths, although the highest mortality occurred in the later months of the year, as is shown by the following abstract:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	817	July	2,871
February	687	August	3,999
March	677	September	2,559
April	800	October	2,049
May	906	November	1,520
June	982	December	1,236

The districts returned 18,411 bowel complaint deaths, equal to a rate of 7·4 per 1,000. The towns returned 633 deaths, or 4·6 per 1,000. The rate for the province was 7·2 per 1,000 against a previous five years' average of 5·3 per 1,000. It seems likely that the higher death-rate of 1883 may have had some relation to the severe cholera epidemic of the same year, as there was a correspondence between the monthly deaths from both diseases.

25. Deaths from *injuries* included 175 suicides, 45 deaths from wounding, 639 from accidents, and 214 from snake-bite and wild beasts.

26. Under "other causes" were registered 29,621 deaths, or 11·3 per 1,000 of the population. The Sanitary Commissioner had made an unsuccessful attempt through the vaccinators to obtain some definite information about them. A similar attempt made in the Punjab has resulted in obtaining important information on the prevalence of chest diseases in that province, so that the object is worth pursuing in the Berars.

27. *Sanitary conditions.*—From what has been already stated it will have been evident that notwithstanding some advance in sanitary improvements the population of the Berars is subject to severe outbursts of fatal epidemics, and one of the problems presented by the Sanitary Commissioner's annual Reports, is that the causes of this epidemic susceptibility should be assigned, and as far as possible removed. The present Report gives a detail of sanitary inspections made by Dr. Little, which ends early in March 1884. There were 72 villages and towns carefully inspected in different localities all over the province, and the result is a very sufficient report and indication of local sanitary defects and disease causes which, no doubt, exist in all unhealthy places, much of the same nature and to a similar extent, although their influence may be locally modified by topographical and atmospheric conditions such as we have already alluded to. Surface cleansing appears to have been attended to in many places, which is, of course, an advance on the former state of matters, but in these provinces as elsewhere in India the real disease causes must be sought within the houses and house compounds. The outskirts of villages are in most cases in a filthy condition from human and animal ordure. Village sites require in certain cases to be extended merely to grant ordinary comfort and convenience to their population. In these villages a great sanitary evil and disease cause is stalling cattle in compounds.

28. A single example selected from each district will give a general idea of these village sanitary problems.

Basim district.—Village Moap. Population, 1,155. "Outskirts dirty, a collection of manure and "refuse of sorts on the road side. On the other side of the village and almost in it are various "accumulations of manure. Inside of village fairly clean, considering that about 800 head of cattle "and 1,500 goats are stalled in it nightly. Best well in a dilapidated state."

Buldana district.—Village Lonar. Population, 2,664. "Patel possesses a copy of conservancy "rules, but they do not appear to be observed. Outskirts of village very foul with human and "animal excrement. Heaps of cowdung, in addition to that put aside for fuel, all round the "village." Road used as a common latrine. "Village inside fairly clean: upwards of 1,500 head "of cattle, are, the patel informs me, stalled in the village at night, and about 500 only are stalled "outside. The villagers, he stated, are gradually stalling more of their cattle on their farms in the "cold and hot weather, but that during the rains they are all stalled in the village." This practice, it will be seen, has a direct relation to the assumed increase of epidemic diseases during the rainy season; out of 10 wells in this village only one contains good water.

Ellichpur district.—Village Takarkhed. "Village very dirty, village sanitary rules a dead letter. "In almost every corner there were heaps of refuse matter, and the bye-lanes are the latrines of the "village." The population of this village is 1,356, and it registered 103 deaths against 67 births in 1883. Of the deaths, 33 were from cholera, 4 from small-pox, 10 from fever, and 34 from bowel complaints.

Amraoti district.—Village Benoda. "The patel and town committee know nothing of the sanitary "rules for villages. The streets of the village were fairly clean, but I noted a good deal of refuse "matter lying about, and accumulations of manure in house compounds. Manure stores or dust-"bins on a large scale outside the village are required." No latrine area set apart. "About 2,000 "cattle are stalled in the village at night, the cowshed being generally under the same roof with the "dwelling-house from which it is separated by a partition wall. Water good." This village has a population of 2,672. There were 126 births registered during the year and 138 deaths, 55 of which were from cholera, and 81 from fever. The other two deaths were accidental, so that the total disease mortality of the year was due to two epidemics, fever and cholera.

Wun district.—Village Kayer. Population 1,695. Village clean. Sanitary rules fairly attended to. This is reputed to be a very feverish and unhealthy village, so much so that it was suggested to the people to remove the village to a more healthy site, but which they will not hear of. The death-rate for 1882 was 40 per 1,000 of population, of which 34·8 were fevers, as compared with 17·6 from this cause for the whole province. The type of fever is intermittent. The people attribute this fever to a stream of water running past the village, but there is also a good deal of irrigated land, a "more "likely cause of the fever." The well water is good.

Akola district.—Village Pathur Nandapur. Population 1,534. "Sanitary rules not attended "to."

Village Kanadi. "Village very dirty. Heaps of dirt and manure in and around village. Patel "has no knowledge of village sanitary rules."

29. The only remark which these examples appear to call for is as follows. The past epidemic history of Berar already stated proves two things,—first, that these diseases have a tendency to recur at stated periods with great intensity; and, secondly, that most of the loss of life takes place in the villages. From the examples we have selected from the Report under review there can be little difficulty in estimating the amount of epidemic susceptibility always present in the 5,564 villages, due in all probability to climatic causes, which of themselves could never account for the facts, but which, with the aid of the prevailing deadly local causes, exert a potent influence on the public health.

It appears further, from the village inspection reports, that certain sanitary rules have been drawn up and circulated among the village patels for their guidance, but in some cases they have been forgotten, and in others neglected. What appears to be wanted are better village executives, for it is quite clear, from the disease history of 1883, that no beneficial influence on the public health can be traced to the exertions of the present officials, under the existing administrative arrangements at least.

30. *Towns.*—We shall add to this abstract, from the village inspection reports, a few notes on the chief towns.

Akola.—According to the census of 1881, Akola town had a population of 16,614. Its death-rate in 1883 was 37 per 1,000, of which 14·5 per 1,000 was due to fevers, and only 2 per 1,000 to cholera, against 9·2 per 1,000 for Akola district. Moreover, its death-rate, 37 per 1,000, during a severe epidemic year, exhibited a marked reduction from the ratio of 45 per 1,000, which ruled during the previous five years. In connexion with these statistical facts, we shall quote the following statement of the Sanitary Commissioner regarding Akola town. He says, "A great deal has been done during "the past year by the Deputy Commissioner, Colonel Fitzgerald, to improve the sanitary condition "of this town. . . . There was a foul and dangerous condition of the house 'moris' and private "latrines. There were no satisfactory conservancy arrangements or supervision of conservancy "establishments, no public latrines, and no system of drainage. Since, however, the Sanitary "Inspection Report of 1881 was written, vigorous action appears to have been taken. Conservancy "and drainage have engaged the serious attention of the municipality, . . . Though much has "been done to improve the town, still it must be remembered that a great deal remains to be carried "out."

In the case of Akola town we have a course of active sanitary work of a simple kind, chiefly cleansing being accompanied by an almost entire immunity from cholera, and by a reduction in the general death-rate from 45 to 37 per 1,000, and we shall next take the case of Ellichpur by way of contrast.

Ellichpur town had a population of 26,728 at the last census. Its five years' death-rate had been 39 per 1,000, but during 1883 this rate had assumed the enormous proportion of 69·3 per 1,000, while the death-rate for the district itself was 65·3 per 1,000. We have already seen that the cholera death-rate of Berar was 10·6 per 1,000. But the weight of the epidemic fell on Ellichpur district, where the cholera mortality averaged 18·5 per 1,000, showing great epidemic intensity. The cholera mortality in Ellichpur town exceeded even the district ratio, and reached 23·7 per 1,000. Premising that the Ellichpur municipality is a poor one, poverty can scarcely be received as a valid reason for the existence of such a state of matters as the following:—"Merely surface conservancy is provided "for. There are no public latrines. Private latrines are not superintended by the municipality, and "owners are said to be held responsible for their cleanliness, which means that they are allowed to "take care of themselves. Besides many, if not the greater number, of these house latrines are "those filthy disease producing abominations called 'peo' latrines, which are merely pervious cesspits "some 30 to 60 feet deep, used by generation after generation. As these get full, or become "unusually offensive, a bag or two of coarse salt is thrown down and the latrine closed for a couple "of days, when it is again ready for use. Of some 1,740 private latrines said to be in existence, "559 of them are computed to be on the cesspit principle." Suppose that in an epidemic country we wished to try an experiment on the localization of cholera, it would not be easy to arrange a better one than this is. There is no analysis of the well water, but it is not improbable that this salting process may have led to brackish well water. Ellichpur stands in urgent need of an organized method of cleansing. All cesspits should be cleared out and filled up at once, and all sewage collected and removed by hand. This is the first work which should be attended to. A good surface drainage system is also required to remove all refuse water due to the projected augmentation of the water-supply. Is it not an imperfect view to take of public sanitary work that, while this deadly condition of the domestic conveniences is allowed to exist, there is an establishment of 16 sweepers and eight carts to clean the streets, where dirt is comparatively of much less injury to the public health than it is in compounds and under the ground occupied by houses?

These two towns are the most populous. The others are large villages, and we shall only select one illustration from among them to show the need of better sanitary administration.

Karatgaon town.—Population, 7,369. "Sanitary rules for villages not known to patel. The "town was dirty. Moris or cesspits abundant, and sullage water from most of the houses runs on "to the streets and filthies the ground around. This is about the dirtiest village I have seen in the "district in this respect. When spoken to about the sanitary rules, the patel replied that the local "committee and not he was responsible for seeing the rules carried out." He was nevertheless a member of the committee, but "there was no unanimity among the members, who seem to be "bickering amongst themselves, and to take very little interest in matters connected with the clean-"liness or health of the town. The patel's house was extremely dirty, with heaps of filth in his "courtyard, dirty mori, and latrine."

31. Of course, in such a state of the sanitary administration, little real work could be done, and the case shows clearly that in these towns there must not only be knowledge of what is required for health, but how it should be done. External pressure might be useful, as it appears to have been in the case of Akola, to the unhealthy state of which we called attention in our Memorandum on the Report of 1881.

32. In certain respects the Sanitary Commissioner reports favourably of the village sanitation. He says, "With regard to the sanitary condition of villages much improvement is manifest in surface "cleanliness, but the provisions of the village sanitary code require more attention," and he points out the following measures, which appear to us to meet the requirements:—"Manure depôts or large "dust-bins situated outside the villages for the reception of sweeping refuse, &c., would be a great "improvement. Extension of village sites where there is over-crowding, some attempt at surface "drainage, and the stalling of cattle apart from dwelling-houses, are the most urgent sanitary "requirements of rural Berar." In our "Suggestions for the sanitary improvement of Indian "stations and their vicinity," we have shown the necessary details for giving effect to economical methods of surface drainage and protection of wells, and to these we are desirous that attention should be directed.

33. *Jails.*—During the last three years a very marked improvement has taken place in the jails at Akola and Amraoti. In 1880 the admissions per 1,000 average strength were 1,046·8 for the former, and 686·4 for the latter. During 1881–82–83 the admissions in Akola jail were 752,322, and 215·2 per 1,000 respectively, and the death-rate, which was 40·3 per 1,000 in 1880, has been since then 12·1, 3, and 11·1 per 1,000 during the three succeeding years. The Amraoti admission rates in 1881, 1882, and 1883 were 708, 297, and 721·4 per 1,000, and the death-rate, which in 1880 was 42·1 per 1,000, had fallen to 17, 8, and 4·9 per 1,000 in the next three years. We have already seen that the five years' average death-rate of Akola town had been 45 per 1,000, and in 1883 it was 37 per 1,000, while the five years' rate of Amraoti town, which had been 23·7 per 1,000, increased in 1883 to 44·2 per 1,000. What has been the cause of this difference in the jail rates? The Sanitary Commissioner ascribes the "marked improvement in the health of these jails to the "improved sanitary condition of the jails with regard to drainage, conservancy, ventilation, over-"crowding, water-supply, and diet,—in fact, to more general attention to sanitary laws."

Jail mortality is subject at times to unaccountable increase, and too much should not be expected from the three years' experience. But here we have two separate groups of people fenced round with suitable measures for protecting their health, and other two groups comprehending the general town and district populations not so well cared for, with the results that, during the great epidemic year 1883, Akola town had a death-rate of 37 per 1,000, and Akola district of 56·4, while Akola jail escaped with a rate of 11·1 per 1,000. In the same way, Amraoti town returned a death-rate in the same year of 44·2 per 1,000, Amraoti district of 54·9 per 1,000, and Amraoti jail 4·9 per 1,000. The facts carry with them their own lesson, just as similar comparisons with jails helped forward the earlier work of sanitary improvement in England, and we must leave them to do so now.

34. *Sanitary Works (Civil).*—These works were partly done by the Public Works Department, partly by municipal committees. To the former belong the conducting of water to the town of Amraoti by a pipe at the estimated cost of 30,264*l.*, which was to be completed in 1885. Two large tanks were also under construction.

In Ellichpur district water was being provided for cattle by tanks and anicuts. In Akola district a tank and two wells were in course of completion, and one tank in Buldana.

There are six municipal towns whose conjoint allotment for all purposes was 16,943*l.*, and their expenditure 15,687*l.* Of this amount 1,742*l.* was spent on conservancy, drainage, water-supply, and other sanitary measures for civil stations. The total expenditure under these heads was as follows:—

	£
Conservancy	5,285
Drainage	1,421
Water-supply	4,430
Other sanitary measures	4,549

Of these amounts there were spent the following for village sanitation:—

	£
Conservancy	550
Drainage	181
Water-supply	1,368
Other expenditures	292
	£2,391

If the amounts expended on sanitary work can be taken as any measure of the possible work done, it cannot be said that it has been commensurate with the necessities of an epidemic country such as Berar. But, indeed, the real work at least in villages, has to be done by the people. So long as such filthy habits and customs exist as those we have only briefly touched on, the main disease causes will continue to act just as they do at present.

That the municipal towns require thorough improvement is shown by the disease statistics, and a comparison with the jail death-rates for corresponding years points clearly to the direction in which improvement should be carried out. So far as we can judge, both municipal and village authorities require very strict supervision to keep them up to their work.

35. Thanks to the Sanitary Commissioner, the disease causes among population groups may be said to be sufficiently well made out to afford ground for practical action, so that the improvement chiefly required in town and village administrations may be proceeded with.

There is one matter, however, connected with the epidemic relation of rainfall which appears to point to drainage defects in sites occupied by towns and villages as those through which the rainfall acts on the public health, and hence general improvements in local relations of sites can be safely advised.

These where necessary, and of a kind to prevent water-logging of the subsoil, together with cleansing and keeping clean, including extension of village sites to enable these all-important improvements to be effectually carried out, removal of cattle from village houses and compounds, and protection of water sources, together with simple impervious surface drains, and the total abolition of cesspits would, so far as we can judge from the facts in this and preceding Reports, soon make a change in the epidemic history of Berar.

Lastly, we must refer for further details to our "Suggestions" already mentioned, but in doing so we have no desire to undervalue the work which has been in progress in past years. All we desire to say is that the disease history in the Report under review shows that it has been insufficient to meet the necessities of the case.

10th April 1885.

No. 9.

Memorandum of the Army Sanitary Commission on the Report of the Sanitary Commissioner for Assam for 1883.

1. The year 1883 is the first year for which the data of vital statistics have been returned for all the districts of Assam.

The total population used as a basis, including that of the Khasi and Jaintia hills, in the present Report is stated at 4,527,934, and the first year's completed results, district by district, have been as follows :—

Districts.	Population, 1881.	Ratio per 1,000, 1883.	
		Births.	Deaths.
Goalpara - - -	446,232	33·39	41·89
Kamrup - - -	644,960	22·56	25·60
Nowgong - - -	310,579	23·91	29·74
Darrang - - -	273,333	21·17	35·71
Sibsagar - - -	370,274	22·49	24·02
Lakhimpur - - -	179,893	18·28	16·27
Sylhet - - -	1,969,009	23·38	25·72
Cachar - - -	289,425	26·73	24·21
Khasi and Jaintia Hills -	43,485	30·19	30·35
Garo Hills (Tura) -	744	59·13	122·31
Total - -	4,527,934	23·91	27·14

The Tura ratios are due to the small population, 744, on which they are calculated, and represent 44 births and 91 deaths.

The first year's completed work gives a general birth-rate of 23·91 per 1,000, and a general death-rate of 27·14 per 1,000, ratios which, if correct, would show a loss of 3·23 per 1,000 of the population on which the ratios are calculated. Both rates are evidently under the truth, but both rates show good registration when all the circumstances are taken into account, and we must hope that as the work has been fairly started, the results in future years may teach us more of the real sanitary condition of the province.

2. Leaving aside the ratios, we find that the births registered in 1883 were 108,269, and the deaths 122,932; the deaths thus exceeding the births registered by 14,663, a loss of population which nothing in the year's epidemic history can in any way account for.

The Sanitary Commissioner also calls attention to the fact that the proportions of births and deaths registered in the districts are subject to considerable annual variations, showing a tendency to relaxation in conducting the work of record. There is, however, nothing in all this to detract from the importance of the registration work already done, while there is every encouragement for aiming at increased precision and greater accuracy.

3. In a former Memorandum we advised that registration of births and deaths should be carried out in the tea gardens of Assam, and the next abstract gives the results for 1883 :—

Districts where Tea Gardens are situated.	Populations yielding Returns, 1883.	Births, 1883.	Deaths, 1883.	Ratios per 1,000 of Tea Garden Population.	
				Births.	Deaths.
Goalpara	1,826	18	42	13·57	31·67
Kamrup	4,806	31	154	16·85	32·04
Nowgong	12,312	222	670	18·03	54·41
Darrang	24,792	438	942	18·47	37·99
Sibsagar	61,519	1,826	2,313	29·84	37·59
Lakhimpur	37,295	310	547	8·31	14·66
Sylhet	27,775	1,091	1,046	39·28	37·66
Cachar	87,266	2,849	2,018	32·64	23·12
Total	257,091	6,885	7,232	26·78	30·97

Referring to these figures, the Sanitary Commissioner remarks that "there seems to be no reason "why the statistics of tea gardens population should not be as near accuracy as it is possible to have "figures, because there must be a muster of all present and an explanation of all absent every day," and yet there are grounds for stating that the mortality in most tea gardens is under reported, "because charitable dispensaries everywhere have the majority of the in-patients from sick tea "coolies who have either deserted from idleness, or to better their prospects, or who have had their "contract cancelled from ill-health, or who are time expired. Such cases in the last stage of "destitution and disease die in large numbers in the dispensaries."

These facts show how difficult it is to arrive at accurate results, but probably some method by means of dispensary returns might be framed from which the registering authority might be able to trace back the numbers and casualties which were due to known gardens. Another and worse reason for inaccuracy appears to be that in certain remote tea gardens there is a temptation to understate the deaths least they should exceed what may be called the Emigration Act allowance of 7 per cent., beyond which there would be Government inspections, and possibly forfeiture of licence.

As these registration questions have been fully raised in the present Report, no doubt they will receive the requisite attention on the spot. As the facts stand, the year's death-rate of 30·07 per 1,000 for both sexes and all ages cannot be said to be high for India, but for a country population engaged mainly in active out-door work, there can be little doubt that it would admit of reduction. We shall return to this subject afterwards.

4. *Death-causes in* 1883.—These were arranged under the customary heads as follow :—

Diseases.	Total Deaths.	Deaths per 1,000 of Population.
Cholera	14,908	3·29
Small-pox	1,462	1·35
Fevers	67,494	14·90
Bowel complaints	14,474	3·19
Injuries	1,292	·27
All other causes	18,655	4·12
All causes	122,932	27·14

The deaths from cholera for the last four years have been returned as follows :—

Years.	Deaths from Cholera registered.
1880	2,803
1881	5,010
1882	21,055
1883	14,908

As the figures stand they would indicate periodical epidemic increase of cholera, now undergoing decline, but this is all that can be said. Cholera deaths were returned from all the registering districts, and from 359 circles of registration out of 678 in the province. There are 18,296 villages, 2,834 of which returned all the cholera deaths.

5. The following abstract gives the monthly deaths for the whole of Assam :—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
January	1,362	July	1,184
February	464	August	519
March	854	September	183
April	2,466	October	63
May	3,725	November	247
June	3,464	December	447

But these totals include two affected regions whose topography and meteorology differ from each other in certain important particulars. They are the two great valleys of the Brahmaputra and Surma, the latter of which has a very large rainfall, and is subject to annual inundations during which it is converted into a kind of archipelago. We have discussed this point in former Memoranda in its relation to times of cholera prevalence in the two valleys, and the causative connexion of rainfall with cholera, and we shall abstract from the present Report the results of another year's observations.

Months.	Registered Cholera Deaths.				Rainfall in Sylhet.	
	Brahmaputra.		Surma.			
	1882.	1883.	1882.	1883.	1882.	1883.
January	611	162	406	1,198	—	·13
February	410	102	459	362	2·84	·15
March	839	360	862	491	13·77	5·42
April	1,281	1,064	635	1,897	18·82	5·91
May	3,663	2,516	449	1,161	23·35	36·30
June	2,993	2,380	590	576	27·76	24·19
July	1,424	1,115	187	64	12·60	19·27
August	426	421	182	23	44·92	29·71
September	141	149	243	33	17·68	22·21
October	81	47	782	12	14·81	2·50
November	129	218	1,628	27	·10	—
December	362	396	2,319	48	—	—

The aggregate rainfall in the Brahmaputra valley, if averaged over the observing stations, may be taken at from 70 to 85 inches. The rainfall in Sylhet was 176·65 inches in 1882 and 145·79 in 1883.

It will be observed that the increase of cholera in the Brahmaputra valley was the same in both years, and lasted from March to July, with a slight increase after October. In the Surma valley the increase follows a similar course, but the two histories do not run parallel. So long as the rainfall in the Surma valley keeps the country flooded cholera is in abeyance, but it increases with the disappearance of heavy rain and re-appearance of the earth surface. Of course, over so large an area of country, averages such as these can scarcely be accepted as scientifically accurate, but they strengthen the conclusion enunciated by independent observers that cholera is related to earth surfaces rather than to areas under water, and hence that it co-exists with ordinary malarial conditions, as long ago pointed out by the late Dr. Bryden.

6. That such conditions are always prevalent in Assam, is shown by the constant presence of paroxysmal fevers over the whole country, and their nature may be easily understood by the following statement made by the Civil Surgeon about the topography of Cachar:—"There is, no doubt," he says, "that much sickness is caused by bad drainage, but the configuration of the district is one we "can hardly remedy. The land slopes from the rivers to the interior, whereas in Europe the land "drains to the rivers. The consequence is, there can be no system of drainage here into the rivers, "for the rivers pour their waters into the interior and fill up the extensive hollows which abound. "It is, in fact, the annual floods and the deposit of silt which is gradually raising the level of many "marshes in Cachar. The people are well aware of this fact, and petitions are constantly being made "asking permission to cut leads from the river to low lands, not to drain the land, but to render them "fit for cultivation by alluvial deposit from the river."

Of course, in a country under formation as Cachar appears to be, any attempt at relief by drainage must be of purely local character, and as the topography must be considered as a constant quantity in the sanitary problem, we must look for improvement in the public health to village and household sanitation. We have long since suggested the adoption of raised houses with free circulation of air below the floor, such as are constructed in Burma, as a remedy against the effect of unfavourable topographical locality; but, no doubt, much in the way of local improvements, even as matters stand, might be effected by usual sanitary measures, such as attention to cleanliness and protection of water. That remedies of this class are urgently required is shown in the report of the Civil Surgeon of Sylhet who "again alludes to the notoriously insanitary condition of both urban and mofussil areas throughout "the district. . . . . No move has been made during the year to remedy the admittedly "insanitary condition of the Sadr station." On which the Deputy Commissioner remarks, that "the "town now enjoys local self-government to a full extent, and it is to be hoped that the Commissioners "will not allow private friendships to come in the way of a due discharge of their duty as regards "suppression of nuisance."

7. The introduction of local self-government is of too recent date to warrant us in looking for practical results, but in India we must expect only very partial results from its operation in public health matters unless some means be devised for keeping the local Commissioners to their work. Local self-government is only a means to an end. As a matter of fact, the highest cholera death-rates of the year were returned from towns. Three of them returned ratios exceeding 12, 13, and 44 per 1,000 (Mangaldai). It is of importance to bear in mind the words of the late Sanitary Commissioner, that "cholera is ever present in the districts of Assam. The valleys of the Brahmaputra and Surma are

" alike endemic areas, and no district is entirely free from the disease. Hence the necessity of constant watchfulness over the sanitary condition of the province.

8. The deaths from cholera, district by district, in 1883, stood as follows:—

Districts.	Deaths from Cholera per 1,000 of Population.	Deaths from Cholera per 1,000 of Tea Garden Population.
Goalpara	2·55	16·6
Kamrup	4·08	5·4
Nowgong	5·09	7·6
Darrang	9·11	8·3
Sibsagar	3·09	5·2
Lakhimpur	2·38	4·3
Sylhet	2·58	3·7
Cachar	1·09	1·9
Khasi and Jaintai Hills	2·08	—
Total districts	3·29	4·4

By comparing the district rates with the average total, it will be seen that the flooded districts suffered least from the epidemic of 1883. We have included in this abstract the tea garden mortality in each district. The coolie population is given at 257,091, and the total cholera deaths were 1,106. The average death-rate exceeded that of the district by 1 per 1,000, and the tea garden rates, with one exception, were higher than the district rates within which they are situated, a result which may be due to better registration in the tea gardens. It will be further observed that the tea gardens situated in the flooded districts followed the same course as regards their cholera death-rates as the district themselves, that is they had the lowest rates of the series.

It may be here suggested whether, considering that the tea gardens population is or ought to be under complete sanitary control, such death-rates should be possible. We have too little information about their economy to warrant us in doing more than asking this question.

There is a story or two of importation into the gardens. One of them is from sweetmeats bought from a man whose mother had died of cholera the same day of the garden outbreak. The dates not answering, the sweetmeat seller is supposed to have "probably" travelled in the wake of a body of infected coolies. The Sanitary Commissioner, we are glad to see, makes short work of this matter, and points out that outbreaks of this nature resemble ordinary village outbreaks, and as such are parts of the epidemic. How much more useful it would have been if the garden medical officer had given a detailed account of the sanitary condition of the garden, and the steps taken to remove disease causes.

9. So far as regards the mitigation of cholera outbreaks, the present Report distinctly shows that there are certain things which cannot be done, and that there are other things that lie within our power. We cannot change the topography, but we can improve the house construction in the way we have suggested, and we can cleanse and keep clean the villages and their surroundings, including protection of water sources. Simple as this recommendation may appear to be, it nevertheless involves difficulties in its execution. But these must be met both in villages and towns, by fairly grappling with them. There is in fact no other remedy.

10. *Small-pox.*—Bearing in mind the present state of registration in Assam, the following figures would appear to show a large increase of small-pox in the year under review:—

Years.	Deaths from Small-pox.	Death-rate per 1,000.
1881	3,129	·69
1882	3,195	·71
1883	6,160	1·37

The deaths in 1883 are not likely to have been over-registered to the extent shown by the data, and the presumption is that registration of deaths has been improving, especially as the table which follows shows that the normal increase of mortality followed the monthly rise in temperature, as usually happens:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	235	July	403
February	322	August	301
March	606	September	201
April	1,139	October	189
May	1,267	November	180
June	1,089	December	280

Small-pox was more or less prevalent in all the districts, but within the districts only 214 registration circles out of 678 returned deaths. In the same way the year's epidemic was made up of 1,572 village attacks from among 18,296 villages in the province.

Out of 21 towns 12 returned 90 small-pox deaths, or in the ratio of ·90 per 1,000 of the town population, while the country rate was 1·37 per 1,000.

Of the year's mortality, which amounted to 6,162 deaths, there were 1,325 registered as under one year of age, and 3,179, or above one-half, as being under 10 years. The lower town rate is attributed by the Sanitary Commissioner to better vaccination and better medical superintendence in the towns than can be obtained in country districts, in many of which the people object to vaccination, while in some districts the real source of small-pox appears to be the inoculator.

There were 182 small-pox deaths among the tea garden population, or 0·71 per 1,000. Referring to the loss of 31 coolies from small-pox in the tea gardens of Darrang, the Sanitary Commissioner says that it "indicates great disregard both of the lives of their labourers, and of the material interests "of the property," from which it may be gathered that no proper vaccination work is in force for the protection of the coolies, at least in this district, for in the present state of the law compulsory vaccination cannot be applied.

11. There are several interesting points of vaccination experience which may afford guidance in improving the service. For example, the Deputy Commissioner of Sylhet says, "One common "complaint among the villagers is that the vaccinator comes and goes, whereas the inoculator is well "known, and visits the patient frequently until recovery. They appreciate this possibly unnecessary "attention. I think it a great defect in our system of vaccination that the operators are generally "*ticca* men, engaged for the season only, and with no interest in their work, except for that limited "time. They know little, and care less for the people among whom they operate, so that it is no "wonder they fail to gain their confidence and co-operation."

Again, anyone familiar with the discussions on the subject of vaccination which have been current in this country, will be able to appreciate the importance of the following remarks of the Sanitary Commissioner on this statement. He says, while adopting the views of the magistrate, "The mothers "have the entire care of the vaccinated child throughout the operation, as the vaccinator rarely "attends to it, except on his official visit to record success or otherwise on the eighth day, and it too "often happens that the febrile distress, the local inflammation, and the sores which follow abrasion "of the vesicles give these poor people more harass than a modified attack of small-pox aided by the "advice and remedies of the inoculator. During my tour this year at Sibsagar, I happened to see a "group of women and children collected round the bungalow of a tea garden, awaiting the visit of a "doctor. I examined them, and found that they had brought all the children with sores following "vaccination. There were nearly 30 altogether. Probably the lymph had been drawn from a "tainted source, as the sores were of the same description. There had been excessive irritation in "the first instance, the vesicle had been scratched, and not only the puncture been turned into an "ulcer, but the lymph carried on the finger nails to other parts, re-absorbed, and fresh ulcers formed "elsewhere. In this case there was proper medical attendance and relief."

It cannot, however, be affirmed that any part of these unfavourable results can be charged against vaccination. Like every other operation, that of vaccination must have a suitable subject, a definite course and a termination, and neglect of any stage in it is just as likely to lead to mishap as would be the case in other operations. There is a close resemblance indeed between these Assam cases and those we have been accustomed to hear adduced in England as telling, not against the manner in which the operation has been conducted, but against vaccination itself, and the Sanitary Commissioner has done good service by telling us exactly what he saw, and in showing that the real remedy lies in better organization of the whole service, under skilled inspection. It may be further suggested for consideration whether the village inoculators might not admit of being trained as vaccinators, and so render useful public service instead of propagating the disease which vaccination is intended to prevent. Their local knowledge of the people might also be advantageous.

12. *Fevers.*—There is the same difficulty in giving a consecutive account of Assam fevers, as is the case with small-pox, on account of the improving registration of the province, and hence the following three years' abstract must not be taken as showing increase of fever:—

Years.	Fever Deaths.	Fever Deaths per 1,000.
1881	42,553	9·49
1882	60,218	13·43
1883	67,204	14·98

There are no doubt grave errors in the disease classification, but on the assumption that errors of this class are constant elements, the rapid increase of fevers would only show extension of registration. Any way the fever mortality assigned to the wet climate of Assam compares favourably with the higher fever rates of dryer Indian regions. Even in Assam, the wettest districts are not the most liable to fevers, so far at least as can be judged of in the present state of the statistics.

13. In the following abstract we have placed in parallel columns the district fever death-rates and the rainfall at the head-quarter towns for 1883 :—

Districts.	Fever Deaths per 1,000 of Population, 1883.	Rainfall, 1883.
		Inches.
Goalpara	22·28	70·54
Kamrup	17·24	59·27
Nowgong	11·59	73·32
Darrang	15·47	70·85
Sibsagar	11·71	85·44
Lakhimpur	7·90	104·36
Sylhet	12·58	145·79
Cachar	11·41	160·44

The fever deaths registered in Lakhimpur are stated not to be reliable, but in the other cases it cannot be said that excess of rain involves excess of fever-rates.

Local topography must also be credited with part of the fever-deaths, as in the case of the excessive fever death-rate, 22·28 per 1,000, in Goalpara, where the 14,494 fever-deaths returned are stated by the Sanitary Commissioners to have been "due in a great measure to the presence of '*kala-azar*,' a "paludal fever, which has attacked the Garos resident in low lands of the Goalpara subdivision. "The deaths in some of the thanas have been enormous, and quite equal to the worst cholera "outbreaks." He adds, "It will simplify the measures of relief, and the medical treatment also, if "it is accepted once for all that '*kala-azar*' is a marsh ague in its causation, intensified through "chronic relapses into a blood taint, which passes into anæmia and chronic congestions, and that it is "only especially fatal because the sick among Garos are left uncared for, unnourished, and exposed "to continual relapses." No doubt lives might be saved, which are at present lost for want of medical treatment, but the account of this *kala-azar*, or black sickness, which we gave in our Memorandum on last year's Assam Report, shows that it is a very fatal form of Terai fever, prevalent in districts situated at the junction of hills with the low Assam plain, occasionally extending up the lower hill ranges, and causing death by visceral complications of a very intense character.

The only real remedy for such fevers is clearing, drainage, and cultivation, or, as an alternative, removing the people. Like other fevers of the class, this *kala-azar* varies not only in amount in different years, but also in locality, and we learn from the Government Resolution on the present Report that in the following year, 1884, the fever had almost left the Garo hills, but had become very prevalent in the submontane villages of Goalpara subdivision.

"While the Garos lived on the hill summits and near the sources of pure water-supply, they seem "to have had no worse fevers than the Nagas and Khasias have now, but since they have occupied "the villages and submerged tracts with a contaminated water-supply they are very much exposed "to the dangerous form of fever known as '*kala-azar*.'" This statement of the Sanitary Commissioner appears to contain the whole sanitary history of this fever. People living in a mountainous country, with facilities for rapidly removing its rainfall, migrate into a Terai region where the mountain drainage stagnates in the subsoil, and suffer from what appears to be a severe form of congestive marsh fever. This is no more than what ought to take place in an Indian climate, and the facts suggest the remedy. The history would have been otherwise if the Terai had been cleared, drained, and cultivated before the people moved into it, but in its present state the best thing for the people to do would be to leave it.

14. As has been already shown, deaths from fever were returned from all the districts of Assam, and the present Report shows that they were returned from 536 circles of registration out of 678. All the towns reported fever deaths, and 11,191 villages out of 18,296 were affected. The town fever death-rate was 13·28 per 1,000 of the inhabitants, and the country rate was 14·94 per 1,000.

15. The monthly incidence of fever deaths stood as follows :—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	5,324	July	6,638
February	4,461	August	5,657
March	4,259	September	5,855
April	4,776	October	5,452
May	6,344	November	5,598
June	7,233	December	5,897

The highest death-rates in the table are those returned in May, June, and July.

The remark made by the Sanitary Commissioner on these data is as follows :—"The unvaried and "perennial mortality exhibited from a disease which, under sanitary improvements, is known to be "almost entirely eradicable, gives rise to some touch of sentiment, even among the dry details of "periodical statistics."

This is quite true, and the importance of the facts to Indian interests will be better understood by bearing in mind that every one of these fever deaths represents some 20 or 30 non-fatal

cases during the same year, every one of which adds its influence in deteriorating the health and working power of the population. Indian fever epidemics must be reckoned as amongst the most potent causes of Indian poverty.

16. The relation of fevers to the general interest of States has been long known. Immigrants, in clearing the land to supply their own necessities, almost invariably suffer in the earlier years, but gradually the land yields its produce, and in proportion as it does so fever diseases decline in amount and fatality; but the contest has always to be carried on, otherwise the benefits already reaped may be lost, both as regards health and increase. Algeria, in ancient times, was a granary, but under the effects of conquest and bad government it became, at least part of it, one of the least productive and most unhealthy of countries. Now, under better auspices, it has reverted to its proper position as a prosperous colony, and has regained its health standard. But the original colonists who began the work were mostly swept away by fevers.

17. We have no new recommendations to make on this aspect of the question, but we may be permitted to recur to what we have often advised when dealing with these fevers, namely, that although climate is beyond our control, the local disease causes, which climate intensifies, can all be dealt with. Villages can be cleansed and kept clean, cattle can be removed from dwellings. Water sources can be kept free of contamination, and houses can be raised above the ground level, as is done in Burma, with the certainty that there will be a decline in fever mortality and better general health in store for the people.

Before leaving the subject of fever we may state that, out of a population of 257,091 in the tea gardens, there were 1,383 deaths from fever, or 5·3 per 1,000 of the population, a ratio which contrasts favourably with that for the country generally, but part of the result may be due to more accurate diagnosis. The fever mortality was about 18 per cent. of that from all causes.

18. *Bowel Complaints.*—Deaths so registered were returned from all the districts and towns of Assam. The death-rate from them in the districts was 3·17 per 1,000, and in the towns 4·47 per 1,000. Out of 678 registration circles, deaths from them were registered in 506, and the year's mortality was returned from 5,329 villages out of 18,296.

19. The statistics of bowel complaints show a similar increase as those of other diseases. In 1881 there were 9,865 deaths registered under this head. In 1882 there were 14,074, and in 1883, 14,273. The increase, however, is only in the registered deaths.

The monthly mortality was as follows:—

Months.	Bowel Complaint Deaths.	Months.	Bowel Complaint Deaths.
January	1,200	July	1,190
February	963	August	1,211
March	899	September	1,313
April	1,029	October	1,224
May	1,406	November	1,258
June	1,415	December	1,366

20. Deaths attributed to this cause gave rise to 2,036 deaths among the tea garden population, or about 8 per 1,000, while the corresponding rate for the whole of Assam was 3·18 per 1,000. The mortality assigned to this cause was not far from double the loss from cholera among the same population, and was by much the most important assigned death cause of the year. The registration in these tea gardens ought to be more trustworthy, as the people are all under inspection, and it is just possible that bowel complaint deaths may take place at the dispensaries in the way already mentioned which are not accounted for in the garden returns. As this matter evidently requires to be investigated, we shall give the district rates for 1883, with the corresponding tea garden rates.

Districts.	Bowel Complaint Death-rates per 1,000 of Population.	
	Districts.	Tea Gardens.
Goalpara	1·42	4·5
Kamrup	1·89	7·7
Nowgong	3·22	15·9
Darrang	3·66	10·0
Sibsagar	5·12	10·3
Lakhimpur	3·61	3·0
Sylhet	3·64	18·4
Cachar	3·38	4·8
Total	3·18	8·0

So far as we can judge, there is a case presented by this abstract which the officer charged with the local inspections may very well take up and devise a remedy for. Food, water, clothing, shelter, and the general sanitary state of the accommodation may all enter as factors into the origin of these high death-rates from bowel diseases.

21. *Injuries.*—Under this head were registered among the provincial population 82 deaths from suicides, 822 from wounds and accidents, and 325 from snake-bite and wild beasts.

22. Under the head of *Other diseases* the following contrasted facts are of interest:—"All the "Medical Officers speak of scurvy as being practically unknown among the people." And again, "Goitre is common in the Nowgong district near Jagi; hardly a house is free from the complaint."

23. Before concluding these remarks on the disease history of the year, we shall notice briefly the facts stated in the present Report about cholera among tea garden coolies on board river steamers. We discussed the subject in our last year's Memorandum, with special reference to the relation between cholera outbreaks on board these steamers while moving slowly up the river through cholera affected districts on each bank, as against the theory that cholera infected drinking water, which had been adduced as the special cause of these outbursts, was the real cause. The infected water theory may be now dispensed with for all practical purposes. It had been acted on; pure water had been provided, and still there was cholera. A crucial experiment had also been tried by transferring a number of affected coolies to a river flat towed behind a steamer on board which were shipped 547 tea garden labourers. Of the coolies on board the flat, 111 in number, one had previously died of cholera. They refused to accept the pure water, and preferred drawing their supply in their vessels over the side from the river. During the upward voyage cholera broke out on board the steamer ahead among the coolies who ought to have used the pure water, and 16 of them, or 25 per 1,000, died.

None of the coolies on board the flat suffered, although their water was drawn from points in the wake of a cholera infected ship. Suppose cholera had broken out on board the flat. Clearly in public health questions theories can only be used as generalizations of multitudes of carefully observed facts, and no induction from a supposed fact or two ought ever to be admitted. We are very glad to see the enlightened course followed by the Sanitary Commissioner on this important matter in the present Report.

24. We shall next give the year's facts in the following abstract:—

Months.	Cholera Deaths in Districts.	Coolies embarked.	Deaths of Coolies.	
			Cholera.	Other Causes.
January	1,862	1,356	—	11
February	464	1,378	—	8
March	954	3,989	38	20
April	2,466	602	8	3
May	3,725	549	5	4
June	3,464	271	4	1
July	1,184	—	—	—
August	445	—	—	—
September	183	—	—	—
October	63	—	—	—
November	247	290	2	—
December	417	469	5	3
Total	14,998	8,905	62	50
Ratio per 1,000 of population	3·29	—	6·9	5·9

We learn from this table that the death-rate from cholera among the coolies during the brief period which elapsed from the time they were put on board until they arrived at their destination, was double the year's death-rate for the province. The shipments in January and in February escaped cholera, as did also the first shipment in March on board the "Sadiya," although during both months cholera existed in all the districts except two, but it must be noted that, of the 1862 district deaths in these two months, one district, Sylhet, which had nearly two millions of people, yielded 1,460 deaths. The subsequent cholera history follows that of the province. The conclusion would, therefore, appear to be that the ship board population came under similar epidemic conditions as those on shore.

We have no means of knowing the precise periods within which cholera deaths took place among any shipment of coolies. But assuming any reasonable period, and reducing this to an annual ratio, there can be no doubt that the losses from cholera are excessive, and ought to be eliminated. We have to deal, in fact, with very intense local outbreaks of cholera on board ship, where the problems to be dealt with are all much simpler than similar problems usually are on shore.

25. It cannot be said that much additional light has been thrown on the subject in the present Report, but there are, nevertheless, facts which afford a certain amount of guidance now that the water theory has been put out of the way.

For example, the tables show that Dhubri town, with a population of 2,893, yielded 40 deaths, or 13·83 per 1,000 from cholera. Dhubri is now the chief port from which tea garden coolies are embarked, and it may happen that people who arrive there from cholera districts have already the predisposition upon them. The following extract from the Report will show how the disease may be

called into activity there :—"It will be observed that the steamers embarking coolies at Dhubri "during January and February (*vide* preceding table), when there was no cholera in the depôts, "carried them up the river to their destination without any appearance of the disease on board, "although cholera, as shown by the registration returns, was never absent in the other districts of "the Brahmaputra valley. It was not till March, when the depôts at Dhubri had themselves "become an infected area, that cholera also appeared after the labourers had been shipped for river "transport." To this statement it ought, however, to be added that cholera was present in January and February in Goalpara district, in which Dhubri is situated, although in no great intensity. Here, however, we have the case, which is by no means a singular one, of passengers from a country more or less infected with cholera arriving at a place where they were detained, and cholera showing itself among them after embarkation. The "Scinde," to which we have already alluded, with its 547 coolies and 15 deaths from cholera, appears to afford another contrast than the supposed cholera water-infection compared with the history of those 111 coolies on board the flat towed behind her. It is evident that a crowd of 547 people must have led to absence of due separation and spreading while steaming through an epidemic region, and it seems not improbable that crowding was one of the causes of the outbreak. On the other hand, we are told that the deck of the flat "being much "encumbered with cargo, the 111 coolies were not massed in a body, but accommodated in groups "of a dozen or so as the deck space allowed."

The following is a very interesting case because it includes two separate experiences. In the month of March, when cholera was fairly on the increase in Assam, the steamer "Burmah" shipped 211 coolies at Goalundo, the lowest port of embarkation, on the 11th, and proceeded up the river. On the 13th, there was a fatal case of cholera on board, so that predisposition had already manifested itself. Three days afterwards, on the 16th, the steamer arrived at Dhubri, where she shipped 281 more coolies, all apparently in good health, and proceeded on her voyage. Five days afterwards, on the 18th, cholera broke out among the coolies, and continued with some severity until the vessel arrived at Tezpur on the 21st. Here the particular gangs of labourers, among whom the disease had appeared, were landed at the depôt and broken up as much as possible. This measure, with care in the matter of food, clothing, &c., put an end to the outbreak, and the coolies were all forwarded to their destination by a subsequent steamer without further disease. In this outbreak there were in all 13 cases and seven deaths. Do not the facts in this case point to overcrowding and its accompaniments as predisposing causes of cholera? Another steamer, the "Rajmehal," took 423 coolies on board at Dhubri at a time when there were 1,700 waiting in the crowded depôts for shipment, and among whom cases of cholera were of daily occurrence. She left Dhubri on the 18th March, "and there can be no reasonable doubt," says the Sanitary Commissioner, "that these "coolies were put on board affected with disease." Indeed, a case had to be landed before the vessel sailed. Afterwards, cases presented themselves almost daily, and before the vessel arrived at Dibrugarh on the 1st April there had occurred 17 deaths, seven from cholera, six from choleraic diarrhœa, and four from other causes, and then follows this important statement:—"The weather "during the voyages of both the steamers, 'Burmah' and 'Rajmehal,' is said to have been fine "and warm by day, but chilly and frequently varied with storms of wind and rain at night. This "circumstance is noted because the coolies are then apt to huddle themselves together wherever "they can find shelter, and it is possible that local overcrowding to a very insanitary degree is thus "brought about."

But there is apparently a far more potent agent at work also, and this is night chill, which may act with deadly effect on a crowd of predisposed people exposed in this way.

26. Cholera among tea garden coolies proceeding to Sylhet and Cachar appears to be connected with the topography and general sanitary condition of the country through which they pass. They are carried slowly along sluggish streams in country boats, and through malarial districts, while if cholera appears among them it is left to run its course. We concur in the opinion of the Sanitary Commissioner that "the sanitary protection of the tea garden labourers in Sylhet and Cachar "urgently calls for more stringent inspection."

27. We have extracted the facts regarding cholera on board the river emigrant steamers, because they go far to explain the causes which have in times past led to outbreaks during the upward voyages, and the most important of these, as proved by the facts, have been overcrowding of surface on board, want of protection, and consequent night chills. But it is very satisfactory to know that the evils have been minimised by the introduction of an accelerated daily service of mail steamers, which make the voyage from Dhubri to Dibrugarh in four days. By their means crowding of depôts is avoided, the steamers having carried away about 175 coolies daily, for the previous nine months, "without any epidemic outbreak of a severe nature."

The remaining lessons of the past should also be utilized, and these poor people sheltered during the cold nights. These precautions, together with striking off seven or eight nights of exposure on the river, ought so far as the present facts go to remedy the evils which have led to discussions in this and former Memoranda.

28. *Sanitary Works (Civil).*—The expenditure account for 1883 includes charges for medical relief, vaccination, drainage, water-supply, conservancy, disposal of dead, roads and culverts, markets and slaughter-houses, and other sanitary improvements effected in 20 towns, unions, stations, and municipalities. The catalogue of work bids fair, but the total expenditure was only 8,348*l*. There is one heading in the return, and this the most important, under which there is no outlay, and this is "village sites," which involve the real sanitary problems of Assam as they do elsewhere in India. Sanitary progress is nevertheless advancing, though slowly, in the towns. It is very satisfactory to learn from

the proceedings of Government on this Report that steps were being taken for supplying every town with good water on a plan already in use. Foul tanks have been filled up, and the work can be done with profit, as the following case adduced by the Chief Commissioner shows. Mr. Campbell, at Gauhati, "selected a tank in a very insanitary position close to a crowded bazaar, filled it up, and "sold the margin of the tank for building purposes, with the result that he covered all the expenses "of the operation and realized a handsome surplus." Similar results have been obtained elsewhere in India, but it is always necessary to use clean material for filling where the ground is to be used for building. Other works are also in progress, as may be inferred from the following abstract of the Sanitary Commissioner's notes on this subject. These contain both facts and criticisms.

Shillong.—The new water-supply for this town of 3,606 inhabitants, which we described in a former Memorandum, was opened by the Chief Commissioner on 6th September 1883. "No station "in India has now a purer or more abundant water service. But on the other hand, "the conser-"vancy of the station requires more control." Latrine accommodation is still insufficient or non-existent.

Dhubri.—This is a great tea garden coolie depôt, and it is stated that "the drainage, roads, water-"supply, conservancy, medical relief, and disposal of the dead, are all in a very rudimentary condition "in this town." Dead are still buried within house compounds. These facts show what has to be done, but, on the other hand, the municipality "has quite recently been formed, and much sanitary "improvement may be expected from the change." We have already seen that Dhubri is a cholera locality during a certain part of the year, an event attributed by the Civil Surgeon to importation, on which view the Sanitary Commissioner remarks, "So long as sanitation depends on principles of "this kind, local improvement is likely to be deferred. In nearly every section of sanitation the "defects of Dhubri are very great, and it is impossible on the evidence adduced not to 'believe' "the probabilities are much greater the emigrants get cholera from causes in Dhubri than that the "disease is brought by them into the town." Clearly the bad sanitary state of the town requires to be vigorously dealt with.

Goalpara.—The drainage works sanctioned for this town were approaching completion, and much work had been done in improving the water-supply, clearing village sites, general cleanliness, cutting down trees when required to admit light to houses, and many tanks and wells were cleared out. The previous five years' average death-rate of this town had been 53·75 per 1,000, out of a population of 6,697. In 1880 the death-rate was 74 per 1,000; in 1881 it was 64. In 1882 it was 60, and in 1883 the rate had fallen to 43 per 1,000. In this case the advance of general sanitary improvement had been attended by falling death-rates.

Gauhati.—The projected water-supply for this town had made no progress, and the people were still obliged to use bad water. Drainage had, however, advanced, and "was of great benefit in a "sanitary point of view." The population of Gauhati is 11,695. Its death-rate had risen from the five years' average of 27·53 to 30·18 per 1,000, of which 4·96 was due to cholera and 6·67 to bowel complaints. "The municipality has a very able medical adviser in the present Civil Surgeon, and "under the guidance of the Deputy Commissioner money is certain to be laid out with great "advantage to the material prosperity of the town."

Sibsagar.—"The sanitation of this station, the head-quarters of a district, is not favourably "reported. The drainage is unsuccessful, from the trace level being originally defective. There "are no public latrines, and the private latrines are never cleaned. The night-soil is deposited in "deep pits. . . . Jungle tracts and cesspools are in the town near dwelling-houses."

Sylhet Municipality.—The Vice-Chairman's report contains abundant knowledge of the disease causes, and "the comparatively infinitesimal action which follows." Nothing could well be worse than the present state of matters, and the Sanitary Commissioner, after personal inspection, says that the picture cannot be overdrawn. There are no signs of material sanitary progress, but the Commissioners have something in contemplation about byelaws. But what can byelaws do in such a state of matters as the following? "Each resident has a large compound, which he allows to be "overgrown with jungle (it is in this compound he digs a small tank, which he utilizes for drinking, "bathing, and washing); that most residents have no privies, but the jungle in their compounds "they use as their commode." Drains are choked, and dead are buried in compounds. Private privies are never cleansed, except under legal process. In such a case as this every facility should be provided to render improvements practicable before they are enforced.

Silchar.—We are glad to learn that this town, unlike Sylhet, not only knows what is needed, but is doing the work, slowly it is true, but steadily.

The other towns in the list do not present any features requiring notice. The Sanitary Commissioner has done his best to tell us how the work is going on, but there is not much of real effective sanitary progress to record for this year at least.

29. Under the head of *General Remarks* there are some statements made by the Sanitary Commissioner on the subject of sanitary reporting which appear to call for notice. Shortly after the principles of sanitary improvement were introduced in India, it was considered to be very advisable to make use of local Medical Officers for inspecting and reporting, because, amongst other reasons, these officers, from their knowledge of diseases and their causes and from the special training they were to receive at Netley Medical School, were at the time the only reliable advisers in sanitary matters available for the public service. It is true that the Royal Commission of 1859 had recommended the appointment of specially trained Officers of Health, as contradistinguished from Medical Officers, because such appointments presupposed not only theoretical knowledge of the subject such as all medical men possess more or less, but training practically in dealing with sanitary problems, which is a different matter, and it is to officers of this class that the recommendation in our

suggestions applies, namely, that their advice should be taken as a ground for action by the executive authorities. But, besides this special provision of trained officers whose advice could be depended on, it has always been found in practice everywhere, as it has been in India, that there are men with special aptitudes for sanitary work, and it ought to be said once for all that in the course of the last 20 years some of the most efficient sanitary officers in the public service have raised themselves from the ranks of the medical profession in India. It is not to the reports of such officers that the criticisms of the Sanitary Commissioner of Assam apply, but to the kind of reporting usually adopted by Civil Surgeons whose special duties lie in another direction, and who may not be possessed of the qualifications requisite in sanitary officers properly so called. With these explanatory remarks, we shall next see what the Sanitary Commissioner says on the subject.

Referring to the epidemic of 1883, he says, "There is the same tendency observable on the part of "Civil Surgeons to lay the blame of an outbreak on causes outside their particular sphere, and to "speak of it generally as an importation. . . . . I need hardly point out again that such con- "clusions are extremely illogical, that they are simply dogmas, and that the etiology of the disease so "expressed is a vain effort to explain the unknown. Until the precise cause of cholera has been "discovered, it is the most scientific course, in the words of the Government of India, to collect the "facts, to record them accurately, and to draw from them no conclusions except those which are "strictly logical." He further calls attention to the fact that cholera is endemic in Assam, and proceeds as follows:—"The next point that calls for remark is the amount of general information "on the true principles of sanitation which is possessed by all the officers of Government in local "authority outside the medical profession." There are "some sanitary reports, both of town and "country, for the year, which are superior to anything I had expected to receive. I can even go "further, and say the best are certainly not those of the Civil Surgeons, and even where the report is "written by a native of the province holding an appointment, perhaps a magistrate and executive of "some outlying township, there is no question but that he is fully informed as to the true sanitary "principles which are required of his administration. On the other hand, the sanitary reports of "the Medical Officers are intensely impractical." But while saying this the Sanitary Commissioner suggests as a reason probably, that hitherto little active work has followed these reports, and the men get tired and discouraged. The district officers' reports show "a sufficient knowledge of the sanitary "requirements of their charges, but not a corresponding energy in pushing relief projects."

It will be observed that these statements raise anew the whole question of sanitary administration, the progress of which now depends less on want of knowledge than in deficient means for carrying out improvements. There are difficulties enough in the path already, and what the Sanitary Commissioner appears to desire is that these should not be increased by the very easy but very dangerous expedient of throwing the blame of epidemics on causes which are entirely suppositious, a course which in times past has given rise to doubts on the whole subject of sanitary work, while it has discredited the advising officers.

The Sanitary Commissioner sets all this aside, and sums up the local case as follows:—"In the "sanitary reports of every town and district which have so far come under my observation, and, in "every part of the country which I have visited, the conditions under which the people live, are all "of them plainly favourable to outbreaks under all circumstances and at all seasons of the year; and "that there is not a single native community in the province which can, with any common sense, "say of another, 'Thou art the man.'" The evils are general, and so must be the remedies.

There is one very hopeful feature in this matter of reporting, namely, the progress made in it by Native Officers. This should be encouraged, because it may lead to examination and inquiry on the spot, and to the spread of knowledge among the people, and also to local interest becoming developed in questions affecting the health of the several towns and villages,—a matter of the highest importance, for the people are really the proper guardians of their own interest in these matters, and one main object of our work is to assist them on the way to become so.

In conclusion. From what we have said it will be learned that we consider this Assam Report as a very good and useful one. We learn from it that the general and local epidemic disease causes incidental to the province have been made out, and are well known to the Government and its officers, and that there is every disposition to grapple with them if pecuniary resources were available. But even in the present state of matters much good work could be done by the personal influence of local officers, and it is in this direction that further effort might apparently be made with benefit.

We hope that local reporting by Native officers may be encouraged, and that, so far as concerns the reports of Civil Surgeons, they may in future be limited to the statement of disease causes, and to practicable remedies, which, in reality, have nothing to do with recondite disease speculations.

If the "cholera bacillus" were accepted as the cause of cholera, it would make not the slighest difference in the sanitary procedure, because the very existence of this supposed cholera cause would involve the presence of unhealthy conditions, differing practically in no respect from those with which the sanitary administration has always to deal.

18th May 1885.

No. 10.

MEMORANDUM of the ARMY SANITARY COMMISSION on the REPORT of the SANITARY ADMINISTRATION of BRITISH BURMA for 1883.

1. The population of British Burma, on which the statistics of births and deaths in this Report are calculated, consisted of:—

Males	1,947,244
Females	1,706,385
Total	3,653,629

Arranged according to classes, this total was made up of,—

Christians	83,786
Mahomedans	168,757
Hindus	87,802
Burmese or Buddhists	3,210,891
Other classes	102,293
Total	3,653,629

Of this population of 3,653,629 the 16 country districts contained 3,227,854, and 20 towns contained 425,775. The fact is here adduced to show anew that Burmese sanitary work is essentially village work, and that if all the towns were improved there would be little perceptible difference in the general death-rate of the province.

2. In 1883 there were registered the births of 43,066 males and 40,669 females, making a total of 83,735 births, or 22·92 per 1,000 of population.

3. Deaths registered in the same year amounted to those of 29,931 males and 23,652 females, together, 53,583 deaths, equal to a death-rate of 14·67 per 1,000, against a previous five years' rate of 16·34 per 1,000. It is evident that both rates are considerably below the truth. Both are means for the whole country, and both include quite impossible ratios for some of the districts.

There is a great difference in the death-rates of towns and country districts, due probably to better town registration. In 1883 the average death-rate for the 20 towns was 25·50 per 1,000, and for the districts 14·67 per 1,000. These differences, moreover, are constant, as appears from the fact that the previous five years' average town death-rate was 28·40, and for the country population 16·34 per 1,000. In the towns these rates are far more reliable than are those for the country circles, and the town rates at the lowest registered, from 15 to 18½ per 1,000, are not very greatly below a year's average for small populations, and 16 out of 20 towns have returned death-rates which evidently are not far from the truth. It follows that the registration problem, like the sanitary problem in this province, lies among the country population.

4. The following were the registered deaths and the assigned death causes in 1883:—

Diseases.	Total Deaths.	Deaths per 1,000.
Cholera	2,185	0·60
Small-pox	675	0·19
Fevers	26,283	7·19
Bowel complaints	2,781	0·76
Injuries	613	0·17
All other causes	21,046	5·76
All causes	53,583	14·67

It will be seen that the low total death-rate is made up of low disease rates, and that above a third of the year's mortality is not assigned to any disease. The fever-rate is nearest the truth, but this table appears to show defective registration under all the heads. We shall next discuss the information given in the Report under each of the heads.

5. *Cholera.*—Of the 2,185 deaths assigned to this cause, 1,861, or 0·58 per 1,000, were returned from country districts, and 324, or 0·76 per 1,000, from the towns. Cholera prevailed more or less in all the country districts, and in 16 out of the 20 towns. There was a diffusion of cholera of low intensity over the whole country, but its incidence was purely local, for although every district registered deaths, the whole mortality was returned from no more than 89 registration circles out of a total of 843.

In the same way there are 14,811 villages in these circles, and yet the whole mortality from cholera was returned from no more than 126. These facts are common all over India, but it is not a frequent occurrence to have this law of cholera epidemics so clearly exemplified by extreme cases

such as the present. Only three of the districts had death-rates fractionally exceeding 1 per 1,000, and few of the attacked towns had rates below this amount. The disease was more fatal in attacked towns than in districts. One town, Pantanaw, had a cholera death-rate of 2·27 per 1,000; another, Lamyethna, had a rate of 4·11 per 1,000; and the highest rate of the year, 4·62 per 1,000, was furnished by Akyab.

6. The monthly incidence of cholera was as follows:—

Months.	Deaths.	Months.	Deaths.
January	759	July	124
February	281	August	94
March	200	September	107
April	312	October	89
May	185	November	26
June	51	December	7

It appears from this abstract as if there had been part of two epidemics of cholera in 1883, the first having passed over from the preceding year. In January 1883 the disease was present in all the divisions, but was most severe in Irrawaddy. In the same month it showed its presence in all the country districts with three exceptions, but all were visited by the epidemic in the course of the year.

7. The next abstract shows the relation of the cholera of 1883 to that of preceding years.

Years.	Deaths from Cholera.	Years.	Deaths from Cholera.
1872	640	1878	6,759
1873	8,109	1879	1,828
1874	960	1880	2,638
1875	761	1881	5,289
1876	3,678	1882	7,177
1877	7,276	1883	2,185

These figures show a tendency to augmentation of cholera in two years' periods, but the apparent irregular mortality in other years may be due to defects in registration. Nothing can be deduced from the data of practical value.

8. As regards causes of local cholera incidence there is very little information in this Report, due apparently, so far at least as the villages are concerned, to absence of facilities for visiting them. The Medical Officer of Akyab says:—"Neither the writer of the present report, nor his predecessor, had "any opportunities for observing personally the sanitary condition of the district towns and villages, "and unless greater facilities are afforded during the present year than have hitherto existed for a "tour of inspection by the Civil Surgeon, the knowledge at that officer's disposal at the close of the "year will continue to be altogether derived from official documents and correspondence. I am "strongly of opinion," he says, "that arrangements should be entered into to enable the district "Civil Surgeon to make annually a tour of inspection of all the principal towns in his district, and "to submit a report to the district magistrate on the sanitary condition of each, noting specially the "nature of the village site and ground in its vicinity, the progress of vaccination, the source and "quantity of the drinking water, &c., and setting forth any recommendations he might wish to "advance for the removal of what seemed to him prejudicial to the general health, and for the "introduction of such measures as might be beneficial. Furnished with this information the district "magistrate would be in a position to instruct the authorities on the sanitary improvements necessary "to the welfare of their villages."

The details of sanitary inspection and work will no doubt necessarily differ in different districts of India, and it must be left to the authorities to arrange both. But we cannot help feeling that this proposal of the Civil Surgeon involves the leading principles on which sanitary work must be done, and it might be well to follow it up in other parts of the country, if found, in such a country as Burma, to be fairly practicable.

9. The following points are referred to as showing the reasons for cholera attacks:—Coolies from India appear to be very liable to cholera in Burma, possibly from its climatic peculiarities. At Akyab, the first outbreak of cholera took place among coolies. It began on the 1st February, made slow progress at first, but prevailed severely in April. There were among these people 168 cases and 98 deaths. "With the commencement of the rains and the departure of the bulk of the coolies "for their homes (principally to Chittagong) the disease ceased." The reporter says, with regard to this outbreak, that "the men were well looked after, comfortably housed in structures erected after "an improved plan, ventilated and raised from the ground, and the surroundings are kept clean. "Latrine accommodation on the trench system is provided at a distance, and the soil is from time to "time covered up. Drinking water is obtained from the best wells in the neighbourhood (no "analysis given). Of course it is impossible to say that this is used by every one." It is further stated that the town residents, although living under more insanitary conditions than the coolies, escaped. It might have thrown more light on this coolie outbreak if the size and cubic space per

inmate in the coolie barracks had been given, because it is known that mere proximity of a considerable number of people, without adequate subdivision, may cause an outbreak of cholera among the susceptible, even in the absence of notable sanitary defects. It is mentioned in the present Report that when cholera attacks people in a place they escape by simply running away and leaving the sick.

10. A second outbreak of cholera took place in the town of Akyab itself on the 3rd July, chiefly confined to Moulapara, "one of the most insanitary parts." After it ceased in the town it attacked the prison. The epidemic was confined within the jail walls, while the neighbouring villages escaped. It ceased on removal of the bulk of the prisoners, and the Medical Officer remarks that "a jail, "however sanitary its condition, is therefore liable to attacks of cholera in an infected and insanitary "neighbourhood. Desert the spot appears to be the watchword for any future outbreak." During the July outbreak there were in all 74 attacks and 59 deaths from cholera.

This Akyab epidemic has afforded additional experience on the dangers that may accrue during cholera invasions from agglomeration of people, and also the necessity of avoiding all such crowding.

11. The Sanitary Commissioner makes the following remarks on the cholera in Prome district. "A peculiar coincidence" is noted by the Civil Surgeon as having occurred at a brickfield, where some cases appeared among the coolies, and "a change of water-supply from the adjacent stream to "the river put an end to the epidemic." But the Sanitary Commissioner very properly states that "if cholera is due to a microzyme introduced into the system in the water for the most part, it is "difficult to understand how the plague can become epidemic in certain villages on a running stream, "whilst others lower down escape." It is more satisfactory to learn that Prome itself had very little cholera, although it is usually afflicted by this plague, and that "the sanitary conditions of the town "have greatly improved."

There is nothing more requiring notice in the history of this year's cholera, except that it is very satisfactory to see that the reports have been mainly concerned with the relation of sanitary defects to cholera, although they would have been more useful if more detail had been given.

12. *Small-pox.*—The following abstract shows the deaths from this disease, together with some details as to age, since 1877:—

Years.	Deaths.	Ages of Children.	
		Under one Year.	Under 12 Years.
1877	1,230	73	205
1878	1,406	222	381
1879	2,297	487	1,147
1880	5,402	921	2,902
1881	1,765	342	838
1882	770	134	372
1883	675	104	365

The small-pox mortality of 1883 was the lowest on record. The rate was ·19 per 1,000 of the total population. The large proportion of children carried off by this disease clearly shows the necessity for directing vaccination work more to the protection of infants than of adults. If the registration could be depended on, we should have to admit that the district death-rate, 0·14 per 1,000, where vaccination is not likely to be very perfect, was only about a fourth of the town rate, 0·54 per 1,000, where vaccination ought to be more extended. In this as in other instances it seems probable that registration has been at fault. Out of 20 towns, nine only reported small-pox deaths, 232 in number, and of these deaths 152 were returned by Rangoon. The disease was present in all the divisions of the province, but of 16 districts six escaped altogether. Out of 343 circles of registration, small-pox deaths were registered in no more than 34, and the whole year's mortality took place in 27 villages out of 14,811 in these circles and districts. We have here another example of a disease which existed over the whole area of a large country being confined as to its mortality to 27 spots only.

The monthly prevalence of small-pox was as follows:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	30	July	52
February	93	August	45
March	92	September	31
April	74	October	48
May	71	November	45
June	67	December	77

13. *Vaccination.*—The following abstract gives the vaccination service and its work for 1883. Under the superintendent there was the following staff:—

Native superintendents	3
First class vaccinators	17
Second class vaccinators	43

The total vaccinations performed during the year were 73,269, of which number 61,901 were reported successful, and the influence of the year's work on arresting small-pox may be estimated by the following statement of the Sanitary Commissioner :—"Of successful cases among children, there "were 8,831 under one year of age, about one-ninth of the number born." This one fact shows where the vaccination service requires direction. It is unnecessary to pursue the subject further, especially as the Report itself is chiefly occupied with the usual departmental details of the vaccination, which do not require notice.

14. *Fevers.*—As usually happens, diseases classed as "fevers," although less fatal in British Burma than they are in India, constituted the principal registered causes of mortality in 1883. Fever deaths were returned from all the districts and towns, and the aggregate year's mortality was 7·19 per 1,000, against a previous five years' rate of 8·41 per 1,000. Of this aggregate rate the districts returned 7·019, and the towns 8·57 per 1,000. The district rate represents the village mortality. Fever deaths were registered in 559 circles out of 843, but here we have again the anomaly that all the country fever deaths were returned from no more than 1,364 villages out of 14,811, although the other data show that fever prevailed over the entire province.

15. We have endeavoured in previous Memoranda to discuss the climatic causes of Burmese fevers, but without much success, on account of the great differences in the elements of climate in different districts. The Sanitary Commissioner has given the following data, which may be introduced, not because they show the whole case. They are, however, all that are available for the whole area :—

Months.	Fever Deaths.	Average Rainfall.	Humidity Average.	Mean Temperature.		
				Max.	Min.	Range.

December	2,058	0·91	70·29	83·45	64·60	18·92

Apparently, when treated as averages, the fever-rate increases with rain and a high rate of humidity, and with high temperature, but then we have the seaside climates, with their excessive rainfalls, much above the average for the whole country. The data in this table can scarcely be said to throw much light on fever prevalence, and, besides, we have been taught by past experience of fever causes that these may be connected with merely local rainfalls, acting on the public health through the agency of local topography and local insanitary conditions. Burmese experience shows that local climates and other local causes influence materially the amount of fever. Thus Arakan division, which has an excessive rainfall, yielded the highest fever mortality, namely, 11·75 per 1,000, while Tenasserim division had a fever-rate of only 5·35 per 1,000 in 1883. These differences are not casual, but represent different rates of fever susceptibility, which it is of great importance to inquire into, because upon our knowledge of the causes depends very much our ability to deal with these fevers practically.

We may give an illustration or two of the relation of fever to rainfall in the districts in 1883. The maximum rainfall of the year was registered at Sandoway. It was 223·09 inches, and the corresponding fever death-rate was 11·45 per 1,000. At Akyab the rainfall was 197·07 inches, and the fever death-rate was 12·02 per 1,000, but under the five years' average, which had been 16·23 per 1,000. Thayetmyo, with a rainfall of 51·27 inches, had a fever-rate of 10·50 per 1,000. Its previous five years' mean rainfall had been 40·92 inches, and its fever-rate 12·04 per 1,000. The lowest fever-rate for the year, 3·41 per 1,000, was registered in Thongwa, while the rainfall of Irawady division, within which it is situated, was between 51·27 and 106·32 inches. The general result appears to be that rainfall acts on local fever causes, and is not in itself a cause.

16. There is no information about local fever causes in the present Report, except as regards Rangoon, which has afforded some interesting experience on the influence of these causes, from which the fever mortality has been rising. In 1882 it was 8·36 per 1,000, and in 1883 it was 10·58. The reasons given are as follow. Rangoon has grown up rapidly and irregularly, and on no fixed plan, and the influx of labourers to meet demands of employers has exceeded the health capabilities of existing accommodation. Labourers employed by firms are better lodged than squatters, whose huts are built immediately over swamps, and both suffer, especially the latter. "The fever is of the "ordinary intermittent and tertiary type. The natives of India suffer most, but Europeans and "Burmese are often affected."

All this leads to loss of labour, and consequent pecuniary loss to employers, and it is said of one firm that in the last quarter of the year they had 17 per cent. of their men on the sick list, involving a loss of 8,644 days' labour. The results of these fevers to the poor people are described by the Health Officer as follows:—"On the 28th and 29th June I visited in all some 52 houses, and found

" nearly a hundred men, women, and little children ill with fever in different degrees of severity. In " some houses whole families were down, and most distressing scenes were witnessed. . . . . " Twenty cases had been suffering for longer than a month, while a few were utterly prostrate, and " in an almost hopeless condition. The fever was generally intermittent." It had, however, a tendency to become remittent. "I believe," he says, "the fever to be of malarial origin, and entirely " due to the fearfully insanitary state of the neighbourhood.

" The spot is typical of what exists in many parts of the district; the houses, most of them of " bamboo, are built over the broad shallow trenches by the roadside and on the adjoining low ground; " the tidal water runs under all the houses, but the mud is exposed for 22 hours out of 24. There " are no latrines, or attempt at conservancy possible, and pigs abound in numbers. The stench " from the putrid mud beneath the houses is at times unbearable. . . . At the end of the rains " in 1880 the people in this same group of houses suffered terribly from malarial and typhoid " fevers."

Here we have one of a class of cases in which people have been left to their fate. We shall follow this up by another in which an effort had been made to protect them. The Officer of Health states that, within a stone's throw of the spot we have described above, " may be seen on the estate " of Messrs. Rowett & Co. what has been done by private enterprise." This is described by Mr. Rowett as follows:—" We began operations about two years ago on lot No. 11, measuring about " 15 acres. At that time the land consisted mainly of swamps and old tanks containing stagnant " and unwholesome water. There was a mound at one corner which had been the site of an old " pagoda long since removed. A few straggling mat-shed houses ran along the creek bank, inhabited " mostly by boatmen and fishermen. Since then we have landed many thousands of tons of ballast " of various sorts, sand, stone, shale, mud, &c. We have removed the mound, which consisted of " shingle and ferruginous clay, brick, &c.; with these materials we have filled in the old tanks, and " raised most of the land until it is fit for good healthy building sites." The land had been laid out in plots to be leased for building. The reclamation was a good work, but in all such reclamations it ought to be remembered that a suitable site for human dwellings requires other things besides reclaimed area. It is not enough, as in the present case, to lay out roads for access to the building plots. The *whole* area should be drained, otherwise time and occupation of area will lead to saturation of the ground and consequent epidemic diseases. But the Officer of Health is right in adducing this case to show what can be done. And in his view, " the future reclamation of this " important district must be carried out by some such method, whereby deep water and serviceable " land may take the place of the many acres of pestiferous swamp which now exist." But care must be taken that only clean and wholesome materials are used for filling in, otherwise the last state may be worse than the first, if the reclaimed area is used for the erection of dwelling-houses.

17. The case of Dala, which we referred to in our last Memorandum, is again discussed in the Report under review, not so much in its sanitary relations as in the administrative course adopted. After describing the abominable condition of the locality, we asked the question " why such things " are allowed to exist?' and we stated that " somebody must be to blame," and we are now told that, " in December 1882 a petition was presented by a number of Burmese residents of Dala, " complaining that a large tank, upon which they were chiefly dependent for their supply of " drinking water, was fouled by squatters near its banks, and who kept ducks and geese, and washed " their clothes and bodies in the tank." The ground, which had been kept clear of dwellings by the Burmese to preserve the water from contamination, was occupied by squatters, and, after inspecting the condition of the place, the Officer of Health reported that the huts of these squatters should be removed, as there was plenty of vacant land where they could be re-erected. The Deputy Commissioner concurred in this proposal, and orders were passed for the men to move their dwellings. Nothing, however, was done, and on a subsequent petition from the Burmese being presented, " it " was found that the Commissioner of Pegu had curtly cancelled the orders of the Deputy Commis- " sioner, and given the men permission to stay." And, as a consequence, " the place is now in a far " worse condition than it was," for the huts have " been enlarged and extended, and on my last visit " I found them crowded by some 200 men." He further says, " The most filthy parts of Dala are " those occupied by the natives of India, and it would not be difficult to point out nearly a dozen " bustis and villages inhabited chiefly by those people which the officers in charge of the land have " allowed to spring up within the limits of the municipality and cantonments during the last few " years," and all this without " scavengering, conservancy, or drainage, ventilation, or prevention of " fire." The Commissioner of Pegu has evidently not been acquainted with the real facts of the case, or he had no power to interfere; any way it is self-evident that the water supply of the Burmese must at any cost be protected, and that the erection of Indian emigrant huts and their sanitary supervision must be put under control. As many as 60,000 of these poor people have arrived from Bengal and Madras in a single year. They crowd into the worst parts of Rangoon, foul every spot of ground about them, and yet we are told that " to mitigate some of these evils the Municipal " Committee submitted to the Chief Commissioner, for approval, a simple byelaw against over- " crowding similar to the clauses in the Municipal Acts of Madras and Bombay; he, however, " declined to sanction it."

18. It is possible that the proposing of such a byelaw was *ultra vires* of the municipality, and if such were the case, it is clear that they should have such a power conferred on them. That power of dealing with these pestilential localities should be lodged somewhere and actively exercised there can be no manner of doubt. And then we have the following statement of the first result of the new municipal constitution, which it is worth while to quote entire to see whether some remedy cannot

be found for its deficiencies, so far, at least, as it concerns Rangoon :—"The delight with which the "European community at least hailed the scheme of local self-government arose from the expectation "that much more would be done for the health and cleanliness of the town than in the past. But it "must be emphatically affirmed that the members have given sanitary matters a large share of their "attention, only to find to their bitter disappointment and discouragement that they are almost power-"less, and that the obstacles to improvement are not those which spring from opposition of ignorant "classes to civilized innovations, but from the carelessness of local officials and former committees in "allowing the city to grow up in an insanitary condition and the neglect of higher authorities to "provide good municipal laws. To the latter cause must be ascribed many of the evils spoken of "in this Report. For years the most important byelaws could not be enforced without troublesome "litigation, which so frequently terminated to the disadvantage of the municipality that an impression "seems to prevail throughout the community that the byelaws are illegal." Many of them have been declared to be so, although drawn up by the Government advocate. And the result is, we are informed, that the Committee have decided to await the passing of a new Act; and the Chief Commissioner himself has stated that "Rangoon is behind many cities of India in sanitary matters." At the time this Report was drawn up the whole sanitary administrative arrangements appear to have been in a state of chaos, requiring a strong and skilled hand to put them in order. We are glad to see that the Supreme Government has called pointed attention to these matters, expressing at the same time their opinion that "it is evident that if any sanitary improvements are to be accomplished, a more "rapid and decided procedure must be devised." Probably this remark will be found applicable to other fever localities besides those in and about Rangoon.

19. *Bowel complaints.*—These diseases (diarrhœa and dysentery) have given rise to the following registered deaths since 1872 :—

Years.	Bowel Complaint Deaths.	Years.	Bowel Complaint Deaths.
1872	4,893	1876	4,640
1873	5,099	1879	3,332
1874	4,860	1880	3,500
1875	5,212	1881	3,808
1876	5,269	1882	3,291
1877	6,879	1883	2,761

Bowel complaints are more common among natives of India than among Burmese, and are attributed partly to sleeping on the ground by coolies and partly to starvation. The total death-rate from them was ·76 per 1,000 against a previous five years' rate of 1·14 per 1,000. The district-rate was ·54 per 1,000, and that for the towns 2·44 per 1,000.

Bowel complaint deaths were registered all over the province, but were limited to 111 out of 843 registration circles, and the whole mortality was returned from 116 population groups out of 14,811. The results are so manifestly unreliable that no further remark is required.

20. *Injuries.*—There were 613 deaths, including 45 suicides and 225 from wild beasts and snake-bite registered in 1883.

21. *All other causes.*—Deaths entered under this head numbered 21,046, or 5·76 per 1,000. The largest ratio of deaths so registered was returned from the towns.

22. *Sanitary Works (Civil).*—Under this head the expenditure on sanitary works and measures for the year 1883 is given for 15 towns, and the following abstract shows the total outlay under each head. The amounts include new works and repairs, but chiefly the former :—

	Rs.
Water-supply	67,920
Drainage	2,987
Scavengering	—
Latrines	6,637
Urinals	—
Markets	112,003
Burial grounds	10,412
	Rs. 199,959

To one of the most important of sanitary measures, namely, cleansing, it appears that no money was devoted in 1883, and although the heading is retained in the statement of sums allotted for the following year's services, there is none for scavengering. It would be better to leave out the heading altogether, for we cannot suppose that no cleansing work was done. It appears to have been otherwise provided for. In the case of Rangoon, it is stated in the town report that Rs. 61,500 was sanctioned for day conservancy, and Rs. 59,600 for night conservancy.

Rangoon has now got its water-supply delivered from hydrants in all the principal thoroughfares, but part of the population still derives its supply from polluted brackish wells, although the new water is preferred. Evidently the next step to take in this matter is to fill up the sewage polluted

wells. There is one matter which appears to be connected with popular habits, apparently admitting of some improvement. It is stated that "bathing and washing of clothes is often carried out at the "stand pipes, rendering their vicinity insanitary and involving much waste of water." These two evils are not consequences of a better water-supply, and they ought to be prevented, and suitable places for both purposes provided. Drainage in Rangoon is still dependent on deep brick channels and surface drains. This large town has still to be drained apparently. The present works are described as follows:—"Surface drains have been improved, and 6,567 lineal feet of drains "have been constructed during the year at a cost of Rs. 36,600. Many streets have been made up "and metalled with laterite. Drainage spaces are being improved, and to the east 10 acres, and "west 20 acres, have been reclaimed." This is satisfactory so far as it goes, but it may be suggested whether the time has not arrived for providing a proper drainage system in connection with the water-supply so that the added water may not become an added disease cause.

23. In the course of the year the Sanitary Commissioner, in the routine of his other duties, visited and inspected 19 towns, and he has given a brief abstract of the results, which, as he states, he also entered in the dispensary books for the information of the authorities, a very proper step, if they only act on it.

The abstracts give a brief general account of the leading sanitary points of conservancy, drainage, water-supply, &c., and the general impression produced by the facts is stated to have been that "there is, of course, in most, much room for improvement, but as will be seen from the summaries "given under sanitary works, much well-directed activity is being displayed."

It will save repetition, if it be stated that water-supply is being improved in many towns by cleansing and deepening wells and bringing in other sources of supply. A scheme for a new water-supply and drainage of Prome has been sanctioned. Drainage is chiefly carried out by surface channels, cleansing is more or less efficiently attended to, but the cesspool system with its dangers still exists, which, as the Sanitary Commissioner states in the case of Akyab, "grow graver yearly." The evils and their remedies have been fully described in our "Suggestions for the sanitary improve-"ment of Indian stations and their vicinity," and we must refer to these for such information as may be required for dealing with them.

It will be seen that the whole year's work refers to towns, and that village sanitation appears to be still a matter for the future.

In conclusion, as we have on former occasions expressed our opinions freely on the defective condition of sanitary administration in Burma, so in the present case we must state that the Sanitary Commissioner appears to have done a good year's work in the midst of his non-sanitary duties. But the present Report contains sufficient information to show that sanitary improvement in the province has scarcely as yet gone beyond the tentative stage, and even this a very limited one. We know enough, however, to enable us to make a strong recommendation that the sanitary administration in Burma should be taken in hand and carried out vigorously, and to enable this to be done executive officers should have sufficient legal powers conferred on them. Far better have no sanitary laws at all than deceptive enactments which exist at present only to impede all progress, and this may be said to be the chief practical teaching of the present Report.

With reference to the statement in the last paragraph, we desire to add that, since this Memorandum has been prepared, we have been informed that, as regards Madras coolie lodging-houses, the legal difficulty has been removed by the Burma Municipal Act, 1884, which empowers local committees to make rules "for fixing and from time to time varying the number of persons who may "occupy a building which is let in lodgings, or occupied by members of more than one family; for "the registration and inspection of such buildings for the notices to be given, and precautions to be "taken in the case of infectious diseases breaking out in such buildings, and generally for the proper "regulation of such buildings."

One of the chief complaints arising out of the past state of the law was that the coolies fouled a water-supply used by the Burmese, and it would appear that no provision of wholesome water is contemplated for coolie houses. It may be that such power can be exercised in conformity with local habits and customs; but it may be pointed out that in the model byelaws for common lodging-houses in this country the following express provision has been inserted:—

"The house should have a water-supply of good quality, and if the water be stored in cisterns "they should be conveniently placed of proper construction to prevent any fouling of water."

In a former Report about Rangoon it was stated that in a case where good water had been provided for the use of coolies they made use of bad water, because it was nearer at hand. It would hence appear that power to prevent the use of bad water might be advantageous.

1st April 1885.

No. 11.

MEMORANDUM of the ARMY SANITARY COMMISSION on the ADMINISTRATION of RAJPUTANA (SANITARY, VACCINATION, DISPENSARY, and JAIL) for 1883.

1. The sanitary statistics of Rajputana fall under two divisions, those for the British districts of Ajmere and Merwara, and those of the Native States.

2. The population of the former amounted in 1881 to 460,722, and that of the Native States to 9,354,163, making together 9,814,855 as the population of Rajputana. But as the statistics are obtained through separate agencies, we shall deal with them under different heads, beginning with the British districts.

3. The births in Ajmere and Merwara in 1883 were, of—

Males	6,633
Females	5,581
Total	12,214

equal to a rate of 26·51 per 1,000; and for every 100 female births there were born 118·84 males.

4. Within the same area there died, of—

Males	4,170
Females	3,419
Total	7,589

equal to a death-rate of 16·47 per 1,000 of the population, and for every 100 deaths of females 121·97 males died. It is evident that these figures are incorrect, otherwise, with a very low death-rate for India, the male population must be undergoing decrease in these provinces.

5. The error is probably confined to 1883, as the previous five years' average death-rate was 25·02 per 1,000, which is much nearer the true rate. The lowest rate of the year, 4·19 per 1,000, was returned from Ajmere suburbs, but the population is only 8,592. The highest rate, 28·99, was returned from Nasirabad town. In this case also there was only a small population of 21,320, but large enough to indicate bad health. Nasirabad rural circle registered a death-rate of 32·28 per 1,000.

6. The following abstract gives the death-causes in 1883 :—

Death Causes.	Total Registered Deaths.	Deaths per 1,000 of Population.
Cholera	87	·79
Small-pox	279	1·25
Fever	4,719	10·24
Bowel complaints	324	1·79
Injuries	261	·57
All other causes	1,119	2·43
All causes	7,589	16·47

As will be seen, cholera was the least fatal epidemic in the British districts. All the deaths took place in a single outburst of the disease, namely, 11 deaths in July, followed by 60 deaths in August, and then 16 deaths in September, with which the epidemic ceased. Fatal cases were returned from 9 out of 23 registration circles, and from 12 population groups out of 739 in the districts; 33 of the deaths were returned from the town of Ajmere, 17 from its suburbs, and 3 from its rural circle, hence 53 out of 87 deaths took place within a very limited area. Nasirabad town had 8 cholera deaths.

7. The following is the account of this epidemic given by the Medical Officer:—"No evidence "appeared showing reason for its onset." In the city those affected belonged to all classes residing "in the different mohullas. They had nothing in common except their residence within the same "area, and there was nothing to show that the disease was imported." This is the usual law of localization, in obedience to which, when cholera has swooped down on an area, every resident within it is liable to attack, whatever may be the nature of his domicile. Some people may yield only cases of diarrhœa, others non-fatal cases of cholera, and others fatal cases. The law appears to be that while cholera is present as an epidemic in a locality, its intensity rather than its presence simply is determined by the sanitary conditions under which the people live, and it follows that fatal cases of cholera may occur in houses where ordinary sanitary observation can discover no adequate cause. In some such cases the causes are strictly personal, as has been long known. Hence the practice of issuing advice in regard to diet, regimen, attention to the state of the bowels, and similar matters during cholera times.

We shall in the sequel give some information about cholera in the Native States.

8. *Small-pox and Vaccination.*—In the British districts small-pox was a much more formidable disease than cholera. It was fatal in 21 registration circles out of 23, and in 169 villages and towns out of 739. Three towns out of five in these districts yielded 53 deaths, and the country circles yielded 526 deaths. The town death-rate was ·50 per 1,000, the country rate 1·42 per 1,000, and the rate of the province 1·25 per 1,000.

9. The following were the monthly deaths registered:—

Months.	Small-pox Deaths.	Months.	Small-pox Deaths.
January	36	July	56
February	47	August	14
March	145	September	15
April	126	October	7
May	76	November	11
June	25	December	21

10. The vaccination service in Ajmere and Merwara, with their population of 460,722 was carried on by six vaccinators. We have seen that the births amounted to 12,234, which number may be taken to represent the available subjects of vaccination, but the actual successful vaccinations under one year of age were only 2,333, or a little under a sixth of the births. Between the ages of one and six years there were vaccinated 1,830 children, while the total successful vaccinations were 4,773. Of the 579 small-pox deaths, 208 took place in children under one year of age, and the whole mortality except 44 deaths fell on children under 12 years of age. It is thus obvious that vaccination requires to be very considerably extended at the younger ages.

11. *Fevers.*—Diseases classed as fevers gave rise to the following monthly deaths in 1883:—

Months.	Fever Deaths.	Months.	Fever Deaths.
January	432	July	352
February	441	August	461
March	440	September	394
April	381	October	362
May	352	November	368
June	376	December	430

The rainfall during the months January to May was 2·61 inches, against a previous six years' average of 1·70 inches. From June to September the fall was 14·52 inches, and the previous six years' average 21·86 inches. October to December yielded ·15 inches, against a previous average of 1·06 inches. The total rainfall in 1883 was 17·28 inches, or 7·34 inches below the average. The data appear to show that the higher rainfall from January to May was attended by a higher fever mortality, while the lower rate between June and September corresponded to a much lower fall. But apparently the low and variable temperature months also yielded the higher fever-rates.

12. Fever was universally prevalent. All the 23 registration circles yielded fever deaths in 1883, and 718 population centres out of 739 suffered. The country fever death-rate was 10·33 per 1,000, the town rate was 9·90 per 1,000, and the rate for the province 10·24 per 1,000. A much larger fever death-rate was returned from some circles than from others, but this is the only practical fact about local causes. One circle, Jasakhera, registered 4·54 per 1,000, which was the lowest, except the rate in the suburbs of Ajmere, which was 1·51 per 1,000, with which may be compared the rate of 17·37 for Pokher circle, proving the influence of locality on fever. There is one hopeful fact, however, and this is the reduction of fever mortality in all the circles below the average. The total fever-rate of 1883 was 10·24 per 1,000, while the preceding five years' average had been 15·88 per 1,000. No account is given of the local conditions under which these various rates have occurred, but the facts would point to differences in sanitary condition.

13. The other death causes in these British districts do not appear to call for remark.

14. *Sanitation.*—Under this head it is stated, that "all the vaccinators have been instructed in the "contents of the Sanitary Primer, and desired to do their utmost in spreading this knowledge "amongst the villagers."

As regards Ajmere itself, it does not appear that much progress has been made with its sanitary works, and the Medical Officer tells us that it "leaves much to be desired from a sanitary point of "view."

15. *Native States.*—Registration of births and deaths in the Native States is carried out by the Native authorities. It is still in a tentative condition, but we are glad to receive such data as can be given, in the hope that before long the results may approach those obtained in the British districts. Returns of births were made in 1883 from Bhurtpore and Jhalrapatan cities, and from Bhurtpore and Jhallawar States. The two cities registered respectively 21·28 and 23·54 per 1,000 births, and the two States 4·83 and 10·65 per 1,000. The facts only show that registration work has been commenced.

16. Deaths were returned from all the registering cities and States. The following abstract, showing the distribution of death causes, may be here introduced to show the present state of the registration. It is, of course, imperfect, but it is creditable to the Native authorities who have supplied the data :—

Native States. Name.	Population, 1881.	Cholera.	Smallpox.	Fevers.	Bowel Diseases.	Injuries.	Deaths, all Causes.	Ratio per 1,000 of Population.
Jeypore (city)	142,587	348	14	1,801	—	—	4,184	29·34
Bhurtpore ,,	66,163	21	—	99	—	1	1,461	22·06
Ulwar ,,	49,867	5	12	396	13	—	910	18·24
Oodepore ,,	35,274	—	5	929	56	16	1,270	35·25
Jhalrapatam (city)	11,469	—	13	85	116	12	237	20·66
Bhurtpore States	645,340	26	90	658	30	8	2,932	4·66
Jhallawar ,,	340,488	77	163	1,285	751	134	2,826	8·29
Total	1,291,319	472	298	5,253	966	171	13,799	10·69

The chief death causes in these States are classed under the head of fevers. Smallpox was a secondary death cause in the Native States, and appears to have been of merely local prevalence. To cope with this disease there were 74 vaccinators, and the successful primary vaccinations of the year amounted to 107,628.

17. We are glad to learn that progress in sanitary work is being made, although much, of course, has to be done in this direction, as the statistics show.

In Jeypore frequent sanitary inspections were made and public latrines provided. Village sanitary rules were also circulated. In Oodeypore city cleansing was carried on.

Ulwar city is described as "probably the cleanest in Rajputana. . . . In the head-quarters of "each of the 12 tehsils more care is taken to secure cleanliness about the wells, and in the streets "and public places, and it is hoped that in time this example may have its effect on the people."

On the other hand it is stated that at Jhodpore "sanitation is much neglected. There are no public latrines, though a staff of sweepers is kept up."

18. Sanitary work, as we understand it, is new to these Native States, but, as the authorities have made a fair commencement with their sanitary statistics, we must hope that they will follow up this primary step by a more rapid advance in efficient sanitation on the lines laid down in our "Suggestions."

19. One satisfactory circumstance stated in the Report is the improved sanitary condition of the jails. There is one jail in Ajmere and 13 in the Native States. The average population of Ajmere jail was 562; the average daily sick was only 6, and the deaths 6, or 11 per 1,000 per annum.

20. The average population of the Native jails was 2,695; the average daily sick, 166; and the deaths 89, or 33 per 1,000. The Ajmere death-rate of 1883 was 15 per 1,000, under the rate of the previous year, and the rate in the Native jails showed a reduction of 3 per 1,000. The chief death causes in all the jails are respiratory diseases and diarrhœa and dysentery.

21. It is satisfactory to learn that "more care is being bestowed on the prisons throughout the "province, in many of which improvements are constantly being made." In the largest of the jails, that of Jeypore, "the water supply has been completed, drainage improved, and tubs supplied for bathing. "Excreta are now removed beyond the jail limits," and the dietary has been improved. At Jhodpore, where eight deaths were caused by dysentery, vegetables are scarce and dear, and mango preserve, with better clothing, are provided.

The new Kotah jail is stated to be "remarkably healthy." There was some overcrowding and tendency to scurvy in Jhallawar jail, but the buildings were being enlarged and anti-scorbutics issued to prisoners. The accommodation in Oodeypore jails is described as "wretched." Ulwar jail was found in excellent order; "sanitary arrangements very good, and clothing and food satis- "factory." In Bhurtpore jail the health of prisoners had improved. Vegetables were issued on alternate days, and cleanliness enforced. Similar remarks are made on Dholpur jail.

A new prison for Tonk was being built.

In conclusion, these are the principal sanitary data supplied by the Report under review. They do not call for special remark. Statistics and sanitary procedure are only of recent introduction in Rajputana, and it is satisfactory to find that both have been taken up by the authorities of Native States, and their results applied usefully. We can only advise that our "Suggestions" may be adopted, so far as they are applicable as a basis of work, and express a hope that future reports may show continuous improvement in the public health.

7th August 1885.

No. 12.

Memorandum of the Army Sanitary Commission on the Report of the Commission appointed under Section 28 of Act IV. (B.C.) of 1876, to inquire into certain matters connected with the Sanitation of the Town of Calcutta.

1. For a number of years past we have called attention to the fact that, notwithstanding the large extent of sanitary work carried out by the Municipal Commissioners of Calcutta in the matters of drainage and water-supply, the city death-rates, especially from diseases of the epidemic class, were still high, and that recently they had shown a tendency to increase.

2. From the detailed information supplied by the annual municipal reports, we were able to trace this unsatisfactory state of the public health past the existing main drainage and water-supply to the foul condition of bustees, wells, and water tanks, and to absence of adequate arrangements for cleansing and removal of domestic filth. It appeared to us as if too much dependence had been placed on the permanent works, to the neglect of those complete and continuous cleansing measures which could in no sense be dispensed with until the permanent works had arrived at such a degree of perfection in application that they could be trusted for doing the work of domestic cleansing, which in the meantime would have to be carried out by hand labour. Many years ago we laid down in one of our Memoranda on the Calcutta Works the leading principle that works of drainage were merely a means to an end, and that their main object was to enable healthy houses to be provided. About the same time, the projected waterworks were referred to us, and we had no difficulty in stating that they would not supply the amount of filtered water required for the daily wants of the population, and that the plans would have to be extended either then or subsequently at a large additional outlay. This unnecessary cost is now being incurred, because there must be a large addition to the water-supply before house and bustee drainage can be effected, and the present Report shows that drainage has been obstructed because of want of sufficient water for flushing drains and sewers. Indeed, for this latter purpose and for street watering a separate supply of unfiltered water has had to be raised from the river by pumping and distributed by a special set of pipes, which in their turn have been found to be too small to convey the required amount of water.

3. Again, the cleansing arrangements were shown by the same reports to be liable to intermitted action, that they were quite inadequate to the public necessities, and that they did not reach the interior of bustees or house compounds, where the real epidemic disease causes were to be found. It was not too much to say that while the municipality deserved great credit for the work they had done, there was no systematized sanitary department, complete in all its parts, and energetically directed from one centre, and as a result there were partial failures in these very departments where such failures were sure to be detected by increased mortality especially from epidemic diseases.

4. The facts had become so well known in Calcutta that public opinion was roused, and the Government of Bengal, in the exercise of a power conferred on it by statute, appointed a Commission of Inquiry, chiefly to report on the state of cleansing, but the Commission soon discovered that they would have to inquire into other matters as well. They inspected many of the bad districts, and took evidence from witnesses. They have embodied the results in the present Report, which contains an exhaustive account of the condition of the capital of India at the present time, and it is not too much to say of this Report and the papers accompanying it, including the proceedings of the Supreme Government and of the Government of Bengal, that, whether for the facts they set forth or for the sanitary administrative principles which they enunciate, they must take rank among the most important contributions to Indian sanitary improvements.

5. The Report itself, which is signed by two of the Commissioners, Mr. Beverley and Dr. Lidderdale, Sanitary Commissioners for Bengal, gives a full digest of the results of the inquiry. They have localized the facts in a way that had not hitherto been possible, although they may not have added much to the validity of the general conclusions hitherto arrived at, and they have shown beyond any doubt that the local causes of the epidemic death-rates have been only very partially reached by the permanent works, and that, so far as epidemics are concerned, drainage extensions to house drainage, drainage improvements generally, and extension of the water-supply are absolutely necessary for the progressive improvement of the city, but that while these are incomplete there are other measures which are of immediate necessity, and which ought to be proceeded with at once.

6. We may here notice very briefly the dissent of Mr. Cotton from the conclusions of the Report. These are mainly grounded on work which has been already done, and on some differences of estimate on the value of the facts. The reply to this is simply that all parties, the Supreme Government, the Government of Bengal, the complainants, the Commissioners in the present inquiry, have done as we have done all along, namely, all have fully acknowledged the value of the work which the Municipal Commissioners have accomplished. This work and its results to the public health are not in question. The complaints refer to work which has been left undone, or only partially done.

7. Leaving out small points of detail, we cannot summarize the sanitary requirements of Calcutta more briefly than has been done by the Supreme Government in the present proceedings. They say: "It was long ago pointed out by the Army Sanitary Commission that the best and only practi-"cable way of reducing mortality and minimising the effect of epidemics in Calcutta is to provide

" the people with pure water to drink, to complete the drainage system and house connections, to fill " up all foul tanks and wells, to level and drain the surface soil, to cleanse and keep clean the city, " not merely as regards its streets, but throughout its private premises and courts, and to reform " radically the bustees and their water-supply." These are all apparently separate items, but in sanitary administration they are one whole, because they are so dovetailed into each other that any defect in the continuity of work may increase the death-rates, and this is just what has happened.

8. Again, municipal Calcutta has outside its present boundary extensive suburbs, and Mr. Cotton not unnaturally points to the higher death-rates of this large population of 250,000 as a proof of great advance in the public health within municipal limits. This is quite true, and is part of the acknowledgment due to the Corporation for its work. But the deduction from it is not that Calcutta has done all that is needful or to justify any delay, but that the suburbs should be incorporated with the town as soon as possible, and the whole brought under one active united sanitary administration, beginning with registration of births and deaths, and including water-supply, drainage, continuous cleansing, and all the other points of sanitary improvement. We are glad to see that this important matter has been taken in hand, and that there is a prospect of the greater part of the vast population of city and suburbs being placed under one consolidated administration at no distant date. The two areas are so connected that even now it is scarcely possible to ascertain what the death-rate of either area amounts to, and even if municipal Calcutta were entirely freed from localizing causes of epidemics, it would by no means follow that the public health would be safe from disease causes left to develope epidemics in the immediate vicinity of the improved area.

9. We have endeavoured to confine our remarks on these papers to the general sanitary principles involved in the discussion, because this Calcutta experience may be said to include points which have arisen elsewhere in India. So far as the special Calcutta incidents are concerned, these have been so fully dealt with in the Report and in the proceedings of the Supreme and Bengal Governments that it is quite unnecessary to enter on them.

10. But besides the special sanitary principles involved there are other two matters of importance in regard to which we are desirous of expressing our entire concurrence in the views put forward by both Governments.

If in India or anywhere else there happens to exist any form of local government charged with sanitary duties for the protection of the citizens, and if it is found by experience that the death-rate, especially from epidemics, does not diminish, but increase, which is the surest test of public obligation imperfectly discharged, neither in India nor anywhere else can the local authority set up the plea of local self-government as any excuse whatever for averting public interference, for the very obvious reason that it has been placed there to prevent the necessity of public interference or complaint.

11. Again, as the need of more active sanitary work has been demonstrated by the Report of the Commission beyond the possibility of doubt, it is obvious that a more liberal expenditure, or a better directed expenditure, will have to be incurred. This additional outlay may, to some extent, be met by vesting all the town sewage in the municipal authorities, and by making it one of the elements of cleansing that this manure should be systematically removed and sold to cultivators. The foul cattle sheds should be dealt with in a similar way. It may be suggested whether the experience of Bombay with its public cattle stalls might not be consulted in this matter. Any way the Calcutta municipal authorities must recognise that of all the unprofitable directions in which public money may be saved, the most unprofitable is that in which the saving is represented by high epidemic death-rates, which represent not only loss of life at the periods when life is of most value to the State, but loss of working power, which destroys the very elements of wealth.

12. It is unnecessary to say more than to express our general concurrence from the side of sanitary improvement with the views of the Supreme Government and the Government of Bengal in these papers, which we hope may have their influence on other local bodies in India besides the Calcutta municipality, and we cannot do better than conclude this Memorandum with the following words:—

" The Governor General in Council trusts that, for the future, the public spirit of the Commis- " sioners will lead them fully to recognise these facts, and that their action will place it out of the " power of any outside critics to impute to them indifference or failure to justify the confidence of " Government in entrusting to their hands the municipal arrangements of the metropolis of British " India. The good effects which have undoubtedly resulted from what has already been done " should encourage the Corporation to organise its operations upon a larger scale, and induce the " community generally to bear cheerfully the heavy burden which the urgency of the reforms " required plainly imposes on it. If in any respect the present law fails to give the Corporation " adequate control over nuisances arising from the action or inaction of individuals, the local " legislature should be moved to amend it."

Backed by such recognition and support, it is to be hoped that, in the words of one of our former Memoranda, quoted by Mr. Cotton, "a glance at the results already attained ought to be the strongest " inducement to perseverance until the capital of India is finally cleansed of its local disease " causes."

19th October 1885.

No. 13.

Memorandum of the Army Sanitary Commission on the Administration Report of Madras Municipality for 1883.

This Report contains the usual details of the Municipal income and expenditure. It is not a sanitary report properly so called, and any information on the subject is mostly limited to statistical data, from which we shall endeavour, as far as practicable, to arrive at some estimate of the year's sanitary history.

1. By adding together the numbers for each of the eight divisions of Madras, the aggregate population amounts to 398,777.

2. Including still-births, the births registered in 1883 were :—

Males	8,447
Females	8,017
Total	16,464

which gives a birth-rate of 41·2 per 1,000, showing that in all probability the population element is under estimated. In one division, indeed, the ratio of births is given as 48·7 per 1,000. Of the births, 1,218 were registered among Christians, 13,364 as Hindus, and 1,882 as Mahomedans.

3. *Deaths.*—The deaths registered in 1883 were :—

Males	7,975
Females	7,907
Total	15,882

or 39·8 per 1,000.

If the population is under estimated, this ratio would be too high. Still, the figures show an increase of 1·4 per 1,000 on the population of the year over the loss by deaths. Of the deaths, 79 were registered among Europeans, 342 among East Indians, 534 among Native Christians, 13,153 among Hindus, and 1,774 among Mohamedans.

4. The year 1883 yielded the highest number of registered deaths since 1872, excepting, of course, the pestilential mortality which accompanied and followed the great famine of 1877. Leaving out the famine, the average deaths registered were 15,059·3 per annum, while, in 1883, the registered deaths were 15,882, showing a rate, above the average, of 822·7 deaths.

5. *Causes of Death.*—The following abstract gives the registered deaths from each assigned cause in 1883, compared with the previous 10 years' average, excluding the famine year :—

Causes of Death.	1883.	Previous Ten Years' Average.
Small-pox	4,957	733·5
Measles	188	69·0
Fevers	3,470	3,329·2
Bowel complaints	2,284	2,327·9
Cholera	169	375·0
Total all causes	15,882	15,059·3

The rise in the death-rates in 1883 was on the side of small-pox, measles, and fever, while mortality from bowel diseases, including cholera, had diminished; but the mortality from diseases of the epidemic class was above 50 per cent. of the mortality from all causes, viz., 8,018 epidemic deaths out of 15,882, while the 10 years' average was 6,730 deaths out of 15,059. We may here remark, in passing, that one main object of all sanitary works and measures is to reduce this proportion of epidemic deaths; and where there is a tendency to increase in the proportion it is a sure sign that there is something requiring remedy. Another similar remark may be made regarding the proportion of deaths under five years of age, which was no less than 51·96 per cent. of the mortality of all ages. No better test of the real sanitary condition of dwellings and their surroundings can be had than this ratio affords.

6. Madras consists essentially of an aggregation of villages, 36 in number. Their average death-rate in 1883 was 37·9 per 1,000. But this rate varied in each of the eight groups into which these villages are divided. The lowest ratio was 29·6 per 1,000 in No. 6 division. The highest ratio, 42·7 per 1,000, was returned from No. 3 division, which contains 52,443 inhabitants in three villages. In one of these three villages there were 417 deaths from small-pox, 25 from measles, and 441 from fever, besides 208 deaths from diarrhœa and dysentery, but there were only two deaths from cholera, showing that, among a population whose epidemic deaths, apart from cholera, were no fewer than 1,091 out of a total mortality of 2,236, the deaths from cholera bore no relation to the epidemic susceptibility of the inhabitants. Cholera was, in fact, a superadded disease, not necessarily related to the year's epidemic history of the locality.

7. The other village groups afford similar illustrations of the fact that, although cholera swoops down on unhealthy localities from time to time, and causes great loss of life, this loss is, nevertheless, a small affair, when compared with the silent, almost unobserved, havoc occasioned by ordinary epidemics in localities where their predisposing causes are continually present. The practical lesson, as regards Madras, is one which has been often enforced, and this is, that the only key to sanitary expenditure and work is afforded by these village statistics, and that those which show the largest loss should be first taken in hand for improvement.

In the next abstract we shall place, side by side, the monthly deaths from epidemics in all the villages:—

Months.	Total Deaths,				
	Small-pox.	Measles.	Fevers.	Dysentery and Diarrhœa.	Cholera.
January	35	10	312	183	—
February	68	10	306	152	—
March	132	9	273	149	1
April	124	10	245	102	—
May	113	6	275	147	—
June	127	13	238	144	—
July	185	12	290	169	1
August	165	14	391	333	—
September	127	9	316	230	2
October	180	9	250	184	11
November	180	11	245	201	68
December	526	25	329	290	86
Total	1,957	138	3,470	2,284	169
Ratio per 1,000 of population	4·9	·3	8·7	5·7	·4

This table shows an augmented death-rate from these epidemic diseases towards the end of the year, and two of them, small-pox and cholera, present the appearance of epidemics in progress and passing over to the year 1884.

Following on this general statement of the epidemic history of 1883, and, in the absence of any information in the present Report on the sanitary condition of affected localities, we shall introduce a few remarks on the sanitary agencies employed for coping with the diseases, beginning with small-pox, which, as we have seen, gave rise to 1,957 deaths.

In 1883 there were 16,069 children born alive, as the subjects alike of small-pox and vaccination. Out of this number of births there were, as corresponding with them, 13,789 successful vaccinations under one year of age, so that these fell short of the births by only 2,280. The successful vaccinations under six years of age were 14,769, and for all ages there were vaccinated successfully 37,138 individuals.

10. The vaccination staff consisted of one Deputy Inspector, 20 vaccinators, and three peons. The percentage of vaccinations to the total population was 10·27, which, no doubt, is a high average; but the deaths from small-pox in 1883 amounted, nevertheless, to 4·9 per 1,000, which is also a very high average. If the ages of small-pox deaths were placed alongside the vaccinations, we should be able to arrive at a better estimate of its value in saving life. All we know is that, while 88·2 per cent. of the births are represented by the proportion of vaccinations, there was a high death-rate from small-pox.

11. Practically, therefore, we must revert to the influence of locality in predisposing people to epidemics, and, amongst others, to epidemics of small-pox, and insist anew on the necessity of improving these Madras villages in all their conditions. But, on this very important matter, there is not much information in this Report.

12. One of the most important works was the completion of drains for diverting the sewage from the Coonm. Eleven and three-quarter miles of surface drains were completed, 314 new house drains (nature not stated) were constructed by owners, and 21 by the Municipality. The backyards of several houses were raised. The cost of drainage for the year was 16,435*l*. We are not in a position to give any opinion on these drainage works. On former occasions we have stated our views fully on facts laid before us by the authorities of Madras, on which we laid down the general principles that the drainage of any town or place involves in it the freeing of the subsoil from sewage and preventing any subsequent infiltration into it.

13. One hopeful feature in the drainage operations is the extension of sewage farming. There are eight farms in operation and a new one has been formed. The receipts on the first eight were Rs. 13,493. 9. 0, and the outlay Rs. 13,014. 7. 9, showing a net profit of Rs. 478. 10. 0. But the actual profit on four of the farms was Rs. 2,251. 7. 9, from which, however, in the general account had to be deducted R. 1,772. 13. 9, which was the loss on the other four. Let us hope that these four may soon return similar profits to the others, and then there would be cause of satisfaction; by another successful application of sewage to agriculture in a locality were manure and moisture are both required.

14. The water supply extension works had also made progress, as is shown by the expenditure of 16,543*l.* during the year. Forty-five miles of pipes had been laid; 311 fountains were in use, together with 674 hydrants.

The quantity of water drawn in 1883 amounted to 137,414,502 cubic feet. With the present reservoir and the rainfall of 55·09 inches, the engineer says, "the supply may now be considered "available to 375,000 people, so that the amount per head per day is 6·4 gallons." As soon as the distribution is completed, all the bad wells should be once for all abolished.

15. The analysis of one out of several water samples drawn from a tap in Royapuram will show the quality of water:—

	Grains per Gallon.
Total solids	15·40
Volatile „	7·00
Chloride	1·96
Free ammonia	·224
Albumenoid ammonia	·168
Nitric acid as ammonia	·84
Total hardness, Clark's scale	3·3°
Permanent „ „	2·1°

This analysis may be taken to represent water from a country surface affording little soluble non-organic material, but a large amount of vegetable organic compounds not necessarily injurious to health, but admitting of reduction by aeration and filtering, which appears to be the result of this analysis

16. *Conservancy.*—This has hitherto been the best part of Madras sanitary administration, and employs a very large staff. In the work of cleansing there were engaged 1,037 men, women, boys, and girls, with the following material:—

Bullock pairs	373
„ single	16
Drivers	389
Carts, contractors' and municipal	420

On house conservancy there were employed 91 bullocks, 60 drivers, 12 coolies, and 272 carts of one kind or another. The hire was, for,—

	R.	A.	P.
Carts	8,527	13	7
Bullocks and drivers	92,208	6	4
Scavengers	66,714	13	8

And the amount of work done was as follows:—

Rubbish cartloads	214,279
Silt „	149,049
Night-soil service,—	
Latrine carts	14,151
Buckets	98,556
Iron carts	17,042

The last three heads include the cleansing work continuously done by sewers and drains in a drained town, where all the sewage matter of a population is removed at once, and as soon as it is produced, to a safe distance, and the subsoil protected from infiltration. Every hour's delay in a warm climate is an hour of danger to the public health, and, notwithstanding the large sums devoted to house cleansing in Madras, London, with about ten times the population, enjoys the immense advantage of being entirely cleansed from sewage within two or three hours of its production.

17. Besides the usual sanitary measures, there were roads made and reformed, and public parks and fountains attended to or provided. And hence, if we were to accept as the best possible the general scheme of sanitary improvement which has been acted on by the municipal authorities, we should have to admit, as a matter of course, that good public health work was being done in the direction which has been chosen. But when we come to apply the epidemic test to a large city on the sea-board, where there ought to be free play of pure air, and little epidemic disease, the statistics at once tell us that there is something wrong. And this is in all probability wet foul subsoil. We are aware that old facts on this point reported by former municipal officers have lately been denied, but since then, as we have noticed in our Memorandum on the Report of the Sanitary Commissioner of Madras for 1882, facts of a similar character have been again reported, and it may be taken for granted that, to the extent to which the subsoil water-level approaches the ground surface of a densely peopled, foul, undrained area, will the susceptibility to epidemic diseases prevail.

18. As the municipal authorities have made their selection, after full discussion, of a scheme of procedure, all we deem it necessary to do is to express a strong opinion that the main reliance in future for protecting health must be placed on perfecting and maintaining the cleansing system, including under this head levelling and improving surfaces, filling up holes, and removing animals from the houses and house compounds in the villages. But when all is done in this direction, there will still remain a large susceptibility to epidemics among the population.

6th August 1883.

No. 14.

Memorandum of the Army Sanitary Commission on the Administration Report of the Municipal Commissioner of Bombay for 1883–84.

1. This Report raises a few questions of a somewhat different kind from those we have dealt with in previous memoranda.

We have here a large city, with a calculated population since the census of 1881 of 807,905, shewing an increase over the census number of 24,709, which has for many years had a water-supply brought from a distance, which has discussed and re-discussed a proposed system of main sewerage and drainage, which, moreover, has spent large annual sums for conservancy, and maintains a large staff for the work, and nevertheless its water-supply is insufficient; its sewerage and drainage, so far as cleansing is concerned, are, to say the least of it, quite inadequate to its wants, and we have the testimony of Mr. Hewlett, the Sanitary Commissioner for Bombay, that, as regards cleansing, this great city remains an "Augean stable." It is true that a city nearly surrounded by the sea has many countervailing advantages in ventilation and in the neutralizing of foul air over an inland city, such, for example, as London, and yet the British metropolis, with a nearly fivefold population, could show a death-rate in 1883 of 20·40 per 1,000, while the rate for Bombay was 29·12 per 1,000. Both cities, moreover, have executive authorities, and it seems not unjustifiable to call the attention of those in Bombay to this very striking contrast, in order that they themselves may discover the causes and apply the remedies.

2. In former memoranda we have admitted the importance of sanitary work done in Bombay, as proved by the lower epidemic rates of years since the work was commenced. We have also adduced the diminishing annual mortality as a proof that the measures which had been in progress were being attended with beneficial results to the public health, and we shall here reproduce the figures, with the addition of those for 1883:—

Years.	Total Deaths.
1877	35,511
1878	26,999
1879	22,527
1880	21,146
1881	21,856
1882	20,468
1883	23,530

It will be seen that, apart from any question of ratios, which are dependent for their accuracy on our knowledge of the population, the continuous reduction in the number of deaths received a sudden check in 1883 by the addition of above 3,000 deaths to the registers. Having stated what was the sanitary problem for 1883, we shall next proceed to discuss the contents of the Report which bear on it.

3. The population of Bombay at the period of the census of 1881 was 773,196. The higher number we have already given is an estimated increase, but we have no proper reason for accepting the assumed law of increase. It has not been proved to be real, and if it be too high it must necessarily lower the death-rate, and so far lead to an incorrect estimate of the real state of the public health.

4. Exclusive of still-born, there were 15,182 living births registered in 1883. There were 1,449 still-born. The birth-rate on the calculated population was 18·79 per 1,000, against about 34 per 1,000 for London, showing a large under registration of births in Bombay.

The registered deaths, exclusive of still-born, were 23,530. On the census of 1881, this registered number would yield a death-rate of 30·43 per 1,000 which is probably nearer the true ratio than 29·8 which would result from assuming the calculated population as a basis.

We should probably be safe in assuming 30 per 1,000 as the true death-rate of 1883, or 4·11 above the ratio of 1882.

6. The following were the assigned death causes, but the ratios are calculated on the assumed increased population, and would probably require a seventh to be added as a correction:—

Diseases.	Number of Deaths, 1883.	Ratios per 1,000 of Population, 1883.	Deaths, 1882.
Small-pox	1,461	1·81	92
Measles	319	·39	991
Fever	5,903	7·31	5,453
Cholera	1,627	1·97	193
Phthisis	3,144	3·89	2,729
Nervous system	2,649	3·53	2,557
Respiratory ditto	3,394	4·20	3,402
Diarrhœa	1,160	1·43	1,003
Dysentery	646	·80	525
Accidents	357	·44	346
All other causes, except still-born	3,270	4·05	3,038
Total	23,530	29·12	20,468

In this table we have added the deaths for 1882, in order to see where the increased mortality in 1883 has taken place. It will be observed that the year's increase amounts to 3,062 deaths. Of this increase 1,369 were due to small-pox, 835 to cholera, 450 to fevers, 88 to diarrhœa and dysentery. The total increase of epidemic deaths, all known to be more or less influenced by local conditions, was 2,742 out of the total year's increase of 3,062 deaths. But there is one epidemic not necessarily connected with local conditions, namely, measles, which showed a large decrease in 1883. Respiratory diseases yielded nearly the same mortality in both years. Phthisis was more fatal in 1883, and this disease is dependent, so far as concerns locality, mainly on overcrowding of population and on the state of the air movement. The increase of diseases of the nervous system depends on another set of causes. We thus arrive at the conclusion that there was a large increase of susceptibility to epidemics dependent on local causes, and that to these the augmented mortality of 1883 was mainly due.

7. The first disease in the list, namely, small-pox, which yielded an increase of 1,369 deaths, or nearly sixteenfold the previous year's death-rate, had assumed an epidemic state in nearly all the districts of the city, and yet Bombay has an effective vaccination service, with the use of calf lymph.

We have already seen that the registered living births in 1883 were 15,182. The successful vaccinations in the same year were as follows:—

Under 1 year - - -	13,355
1 and under 6 years - - -	3,339
Above 6 years - - -	982
Total successful - -	17,676

We thus learn that in 1883 the successful vaccinations under one year nearly covered the births, and nevertheless the deaths from small-pox at ages under one year were 567, or nearly 39 per cent. of the total small-pox mortality; and 991 deaths, or 67 per cent. of the total small-pox mortality took place in children of ages under five. Unless we knew the number of deaths among the vaccinated, we could not state positively that vaccination had failed to this extent; but this efficient Bombay system has been in force for years, and is now compulsory. How, then, are we to account for these results? But there is nothing really singular in them, except the extent to which successful infantile vaccination has been carried on for years in Bombay. Everywhere while vaccination has been a constant quantity, small-pox has notwithstanding been liable to similar epidemic outbursts. It is a pure epidemic disease as well as a disease that may be modified by vaccination, and there is plenty of experience to show that this epidemic character must be met by diminishing the epidemic susceptibility of the people by ordinary sanitary methods.

Bombay cannot, any more than any other city, keep its population free of small-pox by vaccinating its people and leaving their surroundings without effective sanitary improvement, of the need of which this epidemic outburst is the touchstone.

8. *Cholera.*—In 1881 there were 546 deaths from cholera in the city. This number had fallen to 192 in 1882. But in 1883 no fewer than 1,027 cholera deaths were registered. There was a similar outburst of cholera in 1877 and 1878, after 11 years of diminution. This is the usual experience of cholera, and one of the objects aimed at by sanitary work is to break up this chain of sequence by improving the public health during periods of epidemic quiescence.

9. In former memoranda we have shown the very remarkable reduction which has taken place in the annual mortality from cholera since Bombay was placed under sanitary authorities. We have given the statistics for 34 years, the last 17 years of which, under the influence of public health work, lost one third only from cholera of the first 17 years before improvements were taken in hand. In 1874 there were only 19 deaths from cholera; in 1880 there were 30; and, as we have seen, there was a sudden rise to 1,027 deaths in 1883. It does not follow from the statistical facts that sanitary work is less efficient. It may indeed be taken for granted that the condition of the city in this matter was much the same as it was in 1874 when 19 people only died. In 1883 the epidemic prevailed with greater intensity, and it follows that the sanitary measures were insufficient to cope with the year's epidemic force, and no city in which such a mortality from cholera could occur can be considered as otherwise than unsafe.

10. We have besides the independent testimony of Drs. Klein and Gibbes, in their report on cholera, setting forth what they themselves saw in certain cholera localities in Bombay. Referring to two of these localities, Dobie Talao and Cavel, they say that "in both there was an attempt at "drainage; but, owing to the habits of the people of using the street gutters instead, any attempt "of collecting and guarding human excreta must be futile. Not only is this the case, but the excreta "in some streets (owing to the heavy rains) find their way from the waterclosets at the back of the "houses into the streets, and here the liquid sewage can be seen and smelt spreading in the gutters "and all around them. In addition to this there are wells situated in the street, or in some "instances, *e.g.*, in Dobie Talao, at the back of the houses. In both instances the passage of the "liquid sewage into the wells through the defective masonry can be detected without any difficulty. ". . . . The sanitary conditions existing in other parts of the town, and particularly in the "villages, are simply described by the word *nil*." Nevertheless there is evidence that in many parts of Bombay things have been greatly improved since the cholera deaths, with a much smaller population, amounted to 4,000, 5,000, and upwards in a single year.

11. These gentlemen have merely described for us typical cholera localities in a city over whose population cholera is always hovering. We have not yet ascertained how such conditions act,

whether by a specific poison or by the agency of cholera bacilli. All we know is that in such places there are two or three people who will die of cholera without the disease spreading to others in the same house or even in the same room, and the aggregate of such cases marks the epidemic intensity of a particular month or year. All are exposed to precisely similar conditions. All drink similar water, and its comma bacilli, if such happen to be present, have the opportunity of generating the poison of cholera in all of them, and yet, for some reason or other, only a very small minority suffer, proving beyond the possibility of doubt that some other condition besides any of these is required for the development of the phenomena to which we apply the name of cholera. Of one thing, however, we are certain, and this is that, if the local conditions described in the report we have cited be removed, the number of deaths from cholera will diminish or disappear. This is the very work for the doing of which a municipal government exists, and, so far as concerns the presumed "futile" character of attempts at improvement, all that need be said is that sanitary engineering knows nothing of such a word. Not many years ago there were cholera districts in London, Liverpool, and many other English towns of a similar kind, but all have long since disappeared under the operation of ordinary engineering works. It appears to us that this is precisely one of those cases in which an account should be taken of the work which has been done and left undone for the last 20 years, with the view of fixing the responsibilities of these neglects on their authors, and adopting the necessary measures for putting an end to them.

12. We have quoted the facts from the report of Drs. Klein and Gibbes, because they were directed by the Secretary of State to follow up the enquiry of Dr. Koch, and are hence of an independent character, and we shall now see what the Officer of Health of Bombay has to say on the subject.

13. He received notice of 1,474 cases of cholera of a very deadly character, inasmuch as 1,027, or above two thirds, ended in death.

These deaths, month by month, were as follow :—

Months.	Deaths from Cholera.	Months.	Deaths from Cholera.
January	2	July	236
February	1	August	433
March	4	September	152
April	15	October	26
May	84	November	4
June	36	December	37

The data are of importance, because they show that Bombay was visited by a distinct epidemic, which was apparently coming to an end in November after having caused 900 deaths.

In December, however, there were six deaths up to the 18th day of the month, when the Vehar water main broke and deprived the city of water for three days, compelling the people to use wel water and tank water for the time. This accidental circumstance was attended by an addition of 30 deaths to the year's mortality. Cholera being present as an epidemic, it is no doubt probable that some of the 30 deaths may have been due to this forced use of bad water, but there was an epidemic at the same time, as the table shows.

14. In dealing with facts of this nature it is always necessary to apply corrections, and these in the present case are as follow. The Vehar and Tulsi water is brought into the city by water mains, and is a comparatively pure water. The well waters are of the usual type, and the liability to attacks in persons using each class of waters stood thus in 1883 :—

Waters used.	Cholera Attacks.	Cholera Deaths.
Vehar and Tulsi	1,176	828
Well waters	198	142
Not known	100	57

The Vehar and Tulsi supply is intermittent and not sufficient, and it is alleged that to these circumstances, and the consequent use of well waters, some of the mortality may have been due. But the same facts have been repeated year after year, and they clearly show that the pipe water, whether totally or partially used, affords no protection against cholera. But the facts also lead to the conclusion that some other causes for the localization of cholera existed, and these were of the following kind :—

The Officer of Health says :—"On and in the neighbourhood of Navroji Hill, where sanitation was "in the very worst state for this city, and the water-supply least, cholera was most prevalent. The "gullies, drains, cesspools, and general surroundings of the houses were in a bad condition. Many "of the dwellings in which this disease broke out were badly ventilated, badly drained, and "dangerously overcrowded, while imperfectly constructed, and uncleaned cesspools were to be found "in various quarters. Near one house in C ward, where five cases occurred, the condition of the "cesspools was truly appalling. They are so large, and so constantly filled with a dilute solution of "sewage that we, with our inadequate establishment, were unable to keep them clean. . . . . "In Wardi also, the principle ostensible factors in the production of this disease were humidity of "soil and an absence of a pure water-supply, so frequently, indeed almost constantly, are these two

" factors associated with outbreaks of cholera, that it is impossible to avoid arriving at the conclusion " that they are the two principal causes of the conveying (?) the disease."

Mazagon district yielded a cholera death-rate of 2·97 per 1,000 of its population, and of this locality the Officer of Health states that while its better water-supply is liable to interruption "the wells are " liable to be constantly contaminated by percolation from adjoining cesspools, of which there are 174 " in this small section, the contents of which saturate the ground, giving rise to that humidity of the " soil which, combined with impure water, is almost universally associated with cholera."

Parel, with its cholera death-rate of 2·74 per 1,000, and Mahum, which yielded the highest cholera death-rate of the year, viz., 3·63 per 1,000, are in a similar sanitary condition, but in all the cases cited it will be observed that the "subsoil damp" ought to have had its proper name of "sewage infiltration" applied to it, which covers the whole case, and this may be summed up in a few words. These districts, which were the special seats of cholera in 1883, are densely peopled, badly supplied with water, undrained; the sewage passed into the subsoil as the only present means after 20 years discussion about sewers, not of getting rid of it, but of hiding it from view, where it festers and [redacted] air, earth, and water, and when cholera comes the people die.

[redacted] we wonder that European boards of health, with such facts at hand, should insist on [redacted] great commerce of India to quarantine proceedings? or rather, considering the [redacted] sts at stake ought we not to wonder that those whose commerce is thus made liable to [redacted] never cholera increases should submit to the continuance of such a state of their city [redacted]

The [redacted] has long been known, and all that is wanted now is to do the work, which is as much an [redacted] a local affair.

16. *Fever* [redacted] ses so classed were the most numerous death-causes in 1883. As already stated, the registered [redacted] aths numbered 5,903, or 7·31 per 1,000 of the population; of these deaths, 4,439 were reg[redacted] from remittants, 1,169 as from simple continued fever, 275 from ague, and 20 deaths from en[redacted] ver.

17. The *fever de*[redacted] e varied *greatly in different sections* of the city. The lowest rate, 1·04 per 1,000, was returned [redacted] he water division, and the highest, 13·09 per 1,000, from Parel. The *fever death-rate had b*[redacted] lling below the rate of previous years, but in the epidemic year 1883 it *rose like the rates from* cholera and small-pox, and 450 more deaths were registered during that year. The great prevalence of fatal remittent fever points to the existence of adequate local causes, no doubt of the same character as those present in cholera localities. At all events it is not necessary for practical purposes to endeavour to separate the causes. Cholera and fever will both decline in fatality as real sanitary measures and works are carried out in the districts where they prevail.

18. The only other diseases requiring notice are *phthisis pulmonalis* and *respiratory diseases*, from which the mortality in Bombay is very large. Deaths attributed to phthisis numbered 3,144, and to respiratory diseases 3,394. The former are, to a large extent, connected with the densely peopled condition of districts and dwelling-houses. Like other death-rates, those from consumption vary in different localities. The highest local rate of 1883 was registered in Nal Bazaar (Khara Talao). It was no less than 8·67 per 1,000. The remedy for existing evils under this head is opening up localities to admit a free circulation of external air, ventilating the houses, and spreading the population over a sufficient area. It has been long known that other things being equal the mortality from consumption bears a striking relation to the density of population in city districts, and this fact shows that town improvements are necessary in Bombay in addition to drainage, better water-supply, and more active cleansing operations.

19. In the preceding paragraph we have stated the main facts of the disease history of 1883, and we have dealt with the disease causes, as these are described in the same year's Report. After the loss of so much time it was our duty to make the remarks we have made because no future activity can repair the evils already past, although these might have been to a great extent prevented if earlier action in regard to them had been taken. We have never denied that good and necessary work had been done, and that life had been saved thereby, but, in the face of the facts already cited, it can scarcely be said that the present sanitary state of Bombay represents what ought to have been the aspect of epidemic localities after 20 years of sanitary work and expenditure. We shall here leave this point, and conclude our present remarks with a brief abstract of the present state of sanitary works and measures as given in the Report under review.

20. *Drainage and sewerage.*—The arrangements for raising and discharging the sewage at Love Grove were completed and in successful operation early in March 1884. At the date of the present Report the first portion of the new sewerage works, with the necessary manholes and lampholes, had been completed. The sewers appear to have been chiefly pipes, which were found on examination to be all clear. Specifications and contracts had been prepared for the house connexions of the first portion of the new sewerage works, and tenders were invited, but were found not to be satisfactory, so that this all-important sanitary work was still to be taken in hand. The Queen's Road intercepting sewer, by which the nuisance from sewage discharged into Back Bay was to be prevented, could not be completed on account of the heavy rains which stopped the work. The Clerk Road branch of the main sewer with adjacent pipe sewers had been completed. The Kamathipura sewerage works had been virtually completed, but had not at the time been connected with the new sewer. Part of the difficulty in this case had arisen from the obnoxious character of the work, and the disinclination of workmen to engage on it, who moreover preferred to remain idle. The surface drainage of this section had been taken in hand.

House connexion trial works for privies, outdoor sinks, and stables had continued to work satisfactorily. The ovoid sewers from Crawford market and across Byculla racecourse were under consideration, and also a scheme for providing pipe sewers in Agripada district. As part of the surface drainage scheme, the roads and compounds in Khetwadi had been raised and flooding prevented. A number of similar drainage works were in hand, including drainage of the Fort, and forming a flood water reservoir and other details.

21. It will be observed that all these works refer only to main drainage and main sewerage, and that up to the present time there is no evidence that progress has been made in removing the frightful condition of the houses. This is admitted by the Municipal Commissioner, who says in his report that, with the exception of the Kamathipura trial works, "all other house connexions work is in "abeyance, pending the further sanction of the corporation." And as regards difficulties connected with this provision in India he states as follows:—"The great object to achieve for the sanitary "improvement of the city is to carry off polluted water or house sullage by means of the new sewers "and to do this it is absolutely necessary that a mode of ingress inaccessible to storm water "other words above the ground level should be secured. Until this is done most of the ne "are practically useless, and the evils for which they were designed continue unabated." this condition of matters involves the contriving and execution of engineering works mountable difficulty, and the answer would appear to be a direct one, that if this state levels be the cause why sewage is passed into the subsoil to the destruction of h follows, the corporation should apply the remedy which the fact suggests. We have ed by the Report itself to trace the abominable state of the houses and the outbreak up to its source.

22. Before leaving this subject we shall quote the following passage fro missioner's Report, because it appears to point to certain local habits as standing in the w ise drainage improvements; he says:—"Provided there be an efficient system for the sp oval of night-"soil, it matters little (except from a financial point of view) whether the s 'wet' or 'dry.' "The latter is at present, at any rate, the more in accord with the customs as of the inhabi-"tants, but for the removal of sewage other than the night-soil, the duty of ling at once with a "complete system of sewerage cannot be too strongly insisted on." To e this statement it should have been shown by the municipal engineer why the same house d hich convey away the liquid sewage could not be so contrived as to remove an additional 200th p which constitutes about the proportion of solid. This aspect of the question has been long settled, and as regards the financial aspect of it, we find on turning to the Health Officer's report that the total expenditure of the health department was, in round numbers, 84,324*l.*, of which 54,942*l.* was provided by the municipality, and 29,690*l.* in the way of income. We are not told how much of this was spent in removing night-soil, but probably the last sum represents a large part of it. The three per cent. cess for removal of night-soil yielded 23,989*l.* Private service yielded most of the remainder, but it is probable that halalcore work was done for which no cess could be raised. And then, on the other hand, we have the accounts quoted from the Health Officer, and from Drs. Klein and Gibbes, showing what the net present result arrived at by the "dry" removal process amounts to as shown by the abominable conditions under which it compels the poor to live, while the epidemic death-rate completes the account. Such an instance in home sanitary administration might possibly justify the issue of a mandamus.

23. It must, however, be borne in mind that efficient house drainage requires an adequate supply of water, and this necessity has been one of the main difficulties in the question of house drainage. To remove it, proposals were under consideration for increasing the collecting and impounding area of the Tulsi reservoir. Catchwater channels had been completed for increasing the supply of Vehar lake, where filter beds were to be provided, and a new 24-inch main led to Bombay. This new main has been considered necessary in consequence of raising the Bhandarwada distributing reservoir 32 feet higher. When completed, it is expected that the water-supply will receive a daily addition of two million gallons, and will enable the city to receive a million of gallons a day more in April and May. So far as we can judge this work appears to be all in the right direction, but there are facts in the Report which prove that not only sufficiency of water is required, but more extensive and better distribution. Gowari village has been dreadfully affected with guinea-worm. Only one person in it had never suffered from this pest. Again, "there is no doubt of the fact that there is not a hamlet "from Kurla to Parel in which the inhabitants do not suffer from deficiency in the supply of pure "water."

Kurla has no water-supply of its own, and "it is exceptionally prone to visitations of cholera." No doubt this catalogue of defects might be increased, but it is unnecessary.

24. In connexion with the projected increase of water, it must be remembered that the whole of it, not lost by evaporation, must be removed chiefly by house drains, which at present have no existence, or it must sink into the subsoil and increase the epidemic susceptibility of the inhabitants.

The small quantity of night-soil removed, 283 tons per diem, will leave the vast mass of the house water-supply, which will be house sewage unprovided for, and we thus arrive at the conclusion of the whole matter, and this is that house drainage in Bombay should be completed with as little delay as possible, and such methods devised for giving effect to it as are best adapted to the domestic habits of the people; while the increased water-supply should be so arranged that it may pass away, after use, by the house drains. So far as we can judge, the costs of halalcore operations would go far if spent in these new directions to cover the whole outlay required for freeing Bombay and its commerce from the risks attending periodical outbursts of cholera and other epidemics.

8th August 1885.

No. 15.

MEMORANDUM of the ARMY SANITARY COMMISSION on the following Papers:—

1. Report on Enteric Fever in the Madras European Army, 1883.
2. Sanitary Report of Madras Army, 1883, by Surgeon-General Madden.
3. Remarks on Surgeon-General Madden's Report, by the Commander-in-Chief, Madras.

As these papers all refer to the same subject, it will save repetition to include them in the same memorandum.

The average strength of non-commissioned officers and men during the year was 10,612. The admissions to hospital numbered 10,517. The deaths were 108, and the invalids sent home 347. The number constantly sick numbered 633·79, or in round numbers 634. The ratios furnished by these data when compared with the previous 10 years' average, were as follows:—

Per 1,000 strength.	1873 to 1882.	1883.
Admissions	1199·79	991·05
Deaths	14·81	10·18
Invalids	40·34	32·70

Of the invalids sent to England in 1883, 19·13 per 1,000 were for change of climate and 13·57 for discharge from the service.

These data show that the sanitary state of the Madras European Army has been undergoing improvement, and as low as was the death-rate of 1883, it may be noted here that 2·74 per 1,000 of it was due to enteric fever.

2. Leaving out the depôts and small stations occupied by numbers too limited to be used in calculating relative ratios, the next abstract shows the stational death-rates for 10 years compared with those for 1883.

Stations.	Death-rates per 1,000.	
	1883.	Previous Ten Years.
Madras and Palavaram	8·38	14·35
St. Thomas' Mount	5·81	15·14
Cannanore	7·26	12·13
Bangalore	11·89	10·30
Bellary	7·10	10·92
Secunderabad	8·78	14·04
Kamptee	18·76	16·35
Burma:		
Thyetmyo	6·07	16·65
Tounghoo	12·55	13·63
Rangoon	20·78	14·64

These stations accommodate above 9,000 troops, and the data afford approximate ratios for sanitary purposes. It is hence not difficult to single out the offenders, while the considerable reductions at the other stations show that there must be something wrong with those stations where the ratios have increased. The figures, taken as a whole, show that the most unhealthy station for Madras troops is Kamptee in the Central Provinces, to which we have called attention in previous Memoranda. Bangalore is another station where death-rates are persistently high, although it is situated in one of the most healthy climates in India. The Burmese rates, with one exception, are high, but improving, and all the remaining stations have yielded results for one year at least, which cannot be considered as other than satisfactory.

3. The chief death-causes of the year were the following:—

	Deaths.
Enteric fever	29
Remittent fever	3
Cholera	10
Phthisis pulmonalis	6
Hepatitis	13
Dysentery and diarrhœa	6

Deaths from other causes are numbered in ones and twos only, and these larger numbers include the chief sanitary problems of the year.

4. It will be seen that by far the most important death-cause of the year was enteric fever, from which there were 94 admissions and 29 deaths. All the deaths from fever, with the exception of three deaths from remittent, were attributed to this fever. In a 10 years' period, 1873 to 1882, the average annual strength was 10,934, and the total fever admissions during the 10 years amounted to 28,760, or in the ratio of 263·03 per 1,000 of the aggregate strength. In the same period the fever deaths were 189, or 1·73 per 1,000, and of these deaths 126 were attributed to enteric fever. It follows that although the admissions from this fever type do not influence materially the admission-rate from all fevers, the fever death-rate depends mainly on the greater or less prevalence of enteric fever, and to the high death-rate from this disease is due the rise in the fever death-rate of 1883 to 3·01 per 1,000, while the previous 10 years' average rate was 1·73 per 1,000.

5. The next abstract gives the prevalence of this fever according to season.

Seasons 1883.	Enteric Fever.	
	Admissions.	Deaths.
1st quarter	7	3
2nd "	14	4
3rd "	60	16
4th "	13	6
Total	94	29

In 1883 the hot and rainy months were those of its greatest prevalence and

6. The usual liability of young ages and early service was observed in 18 s, out of these 94 admissions, and 29 deaths, 71 admissions and 24 deaths took place in m 5 years of age, and 66 admissions and 19 deaths occurred at periods of service under 2 ye e facts are stated simply as confirmatory of past experience, and the practical conclusion is, fever death-rate is mainly influenced by the ages of men sent to India.

7. There are certain apparent anomalies connected with liability to enteric fever to which attention is called by the Surgeon-General. For example, he states that while 19·48 per 1,000 of officers were attacked, none of them died, but that 8·86 per 1,000 of the men suffered, and 2·73 per 1,000 died. In the same way he shows that no children were attacked, but that among women the attacked were in the ratio of 4·86 per 1,000, and the deaths 2·43 per 1,000. As a rule, the admission-rate among officers is higher than in any other class, and the Surgeon-General makes the remark that, "Although "these figures are too few to establish any reliable conclusion, still the greater prevalence of the "disease amongst officers would seem to imply that defective sanitation is not the only cause of the "disease in India, as it is to be presumed that the officers live under better sanitary conditions than "either the men or women." This observation is fully borne out by the facts he cites, as well as by those in regard to age and periods of service already cited, because it is evident that among troops, all of whom are exposed to the same sanitary or insanitary conditions, liability to enteric fever is influenced by age, and by the time men have been in the country. It may be that insanitary conditions act more powerfully at the more susceptible ages, but as an ultimate fact young ages are the fever ages, and it is possible that the greater liability of officers may be due to this element, but if so, it would not account for the non-fatal character of the fever among them, and this raises the question of diagnosis, which lies beyond our sphere.

8. But notwithstanding this aspect of the fact, the present Report contains points of importance regarding local sanitary conditions which we shall next refer to. The first of these is the amount of enteric fever at different stations. This is shown in the next abstract.

Enteric Fever Stations.	Average Strength, 1883.	Enteric Fever.		Deaths per 1,000.
		Admissions.	Deaths.	
St. Thomas' Mount	344	1		—
Bangalore	1,844	11	11	6·0
Bellary	986	8	5	5·07
Wellington	614	4	1	1·6
Secunderabad	2,276	28	7	3·08
Kamptee	693	10	4	5·8
Seetabuldee	50	1	1	20·0
Thyetmyo	659	1	—	—
Total	7,466	94	29	3·88

The first, fourth, and two last stations in this list may be left out of the discussion. But it is evident that there are four enteric fever stations, viz., Bangalore, Bellary, Secunderabad, and Kamptee, which must be dealt with. The facts regarding these stations have been so frequently under discussion that it appears to be scarcely necessary to refer to them, were it not that certain of them are pointedly noticed in the Surgeon-General's Report. Beginning with the negative evidence,

he says, "The strictest attention is paid to the sanitation of barracks and their surroundings, of "latrines, and of food and water-supplies, and no reasonable expenditure that can promote and "protect the health and comfort of the soldier is denied. Latrines are all worked on the dry-earth "system, and kept scrupulously clean, but although dry earth is a most perfect deodorant, it is "impossible to say that it is an equally efficient disinfectant." This merely means that enteric fever takes place where these latrines are in use, but it does not follow that there may not be effluvia, not markedly offensive, that are capable of acting as disease causes. This fact has been long known, and hence the old sanitary rule that immediate removal of all sewage matter to a distance is alone the safe course to follow. "Speedy removal of the defiled earth is aimed at, but it is," he says, "not "always possible to get the soldier to throw in dry earth on using the latrine." Of course neglect of this precaution *pro tanto* nullifies the end of the dry-earth system.

9. Although the food supplies generally are "above suspicion," there is an exception as regards [redacted] and "it is within the range of possibility that milk may at times be supplied in tainted vessels, [redacted] vendors do not appreciate or understand the fastidiousness of the European in the matter of [redacted]. In fact, the native idea is that water of any kind purifies everything with which it comes [redacted]"

[redacted]ow how far it may be possible to find a practicable remedy for this practice, but we [redacted]mind, notwithstanding the occurrences of enteric fever cases among women already [redacted] milk drinkers, the women and children, usually escape enteric fever.

[redacted]ts are of general application to all stations, as is also the fact that water sources for tr[redacted]ully guarded and periodically analysed. But here we are met by the Bangalore experie[redacted] with its foul water source and its 6 per 1,000 enteric fever death-rate in 1883. Practically there has been no real change in the water-supply from the Ulsoor tank of this large station since its dangerous character was laid before the Royal Commission of 1859. The singular thing is that the facts and their importance are admitted by everybody, and yet nothing is done. The last thing tried was boiling the water.

"With reference to the Ulsoor tank and its dependent wells which supply the whole of the "waters used by the troops at Bangalore, the Medical Officer, North Station Hospital, remarks. "... This channel (the feeder of the tank) was from time to time during the year defiled by "the Natives, who used it as a latrine, and the water of the lake itself was polluted by Natives "washing in it themselves, their clothing and cattle."

11. Referring to the causes of enteric fever at this station, the Medical Officer of North Station Hospital says:—"No insanitary defects could be discovered within barracks. The water-supply "(mixed water from the Ulsoor tank and Dhobie's wells as usual) was impure from contamination "by excrement and filth of every description. There is not only the immediate danger from pollution "of the water-supply tank, but as a portion only of the filth washed into it becomes oxidized and "innocuous, the remainder is deposited on the bed of the tank, ready to give forth in the dry season, "when the water is low and the bed of the tank (125 acres in extent) is exposed to the sun, the "noxious vapours which, in conjunction with the use of the water, predispose to, if they do not "directly cause, the fatal form of fever."

This statement regarding the condition of Ulsoor tank in dry weather introduces for the first time an element of disease into the discussion which has never hitherto been mentioned. The alleged fact should be further inquired into, and some attempt might be made to trace any time relation which may exist between the drying up of the tank and the appearance of enteric fever among troops. It has been long known that there is a relation between fever types, including typhoid fever, and the condition of pond surfaces. Even in India there is reason to believe that such relation has shown itself at Neemuch and elsewhere, and the importance of the fact as regards Bangalore, if it should turn out to be correct, would point to the draining of the tank and cultivating its area as parts of the necessary remedy for this fever.

12. Referring to the condition of the tank as well as to the state of the water, the Surgeon-General himself says, "The conditions referred to in these extracts are in my opinion sufficient to "account for the prevalence of enteric fever at Bangalore," and he further expresses his opinion that, if great care had not been exercised in purifying the tank water before use, "there would have "been, instead of isolated cases, a general outburst of the disease."

13. The Adjutant-General, in referring to the water-supply of Bangalore, states that it is got "from the Ulsoor tank and the Dhobie's wells, is filtered at the tank, and then distributed in pipes "by steam power. On delivery it is passed through Mackenzie's filters, and from July to October "1883 it was further deemed advisable to boil it before issue. The water-supply of this station is "precarious and scanty, and liable to dangerous pollution. During the year the subject received "the earnest attention of Government, and it is hoped that in due time it will be found practicable "to give Bangalore, which has so many other advantages as a military station, a better water-"supply." This statement might have been made any time within the last quarter of a century, but the new aspect given to the whole question by the Surgeon-General in the present Report, appears to show that while better water should be provided as a necessity, the state of the tank in dry weather and its relation to fever should be investigated.

14. Kamptee stands next in order of liability in enteric fever, with its death-rate of 5·8 per 1,000. The Deputy Surgeon-General, however, states that the sanitary condition of the barracks and lines, the food, and water "have not led to any conclusions that they are the origin of the disease, so far as

"these matters are controlled by the regimental and medical authorities." The relation of enteric fever at Kamptee to seasonal influence is stated as follows:—"The cases occurred only during the "last four months of the south-west monsoon, and at the same season that fevers caused by malaria "are most prevalent here, and from the similarity to remittents in some cases, it is," I think likely," he says, "that the enteric fever at this station is in some way connected with malarial influences."

The question may here be asked whether any part of the station is liable to flooding during the monsoon to such an extent as to give rise to slow drying up of the ground or to disturbance of the subsoil and wells?

In the course of the year the remodelling of the infantry barracks at this station was completed, and "they are now well raised above the ground, have broad verandahs and excellent ventilation." The effect of these improvements on the amount of fever should be noted, but from the facts as they stand it appears probable that the condition of the subsoil at the station and in its neighbourhood may exercise a not unimportant influence on the amount of fever.

15. As already stated, the death-rate from enteric fever at Bellary was 5·07 per 1,00[illegible] account is given of the reasons for this high death-rate.

16. *Secunderabad* yielded 28 enteric fever cases and 7 deaths in 1883, equal to [illegible] 3·08 per 1,000. The following account of the cases is given by the Medical Officer [illegible] hospital:—"The manner in which the cases occur, scattered through the bar[illegible] "at different periods of the year, appears to point to a common origin o[illegible], "which originating cause is always in existence, and to which all the men [illegible]pose "themselves, such a source of disease might easily be found in the filth of [illegible]zaars "and Native prostitutes' houses."

This amounts to a statement that, although much has been done for improvi[illegible] of troops at this station in past years, there are still general filth causes in places to [illegible]esort which may predispose them to enteric fever. But there are other disease-causes at [illegible]hich attention has long been directed. "There is some wet land under cultivation near the [illegible]antry barracks "which it would be desirable to drain and plant with trees, but this has [illegible]id practicable, "as the owners object." This wet land has often been complained of, an[illegible]ot be drained we may suggest that a belt of vegetation might be planted between it and the [illegible]s. The following statement is made about the drainage:—"The drainage of the barracks was improved and is now as "good as it can be without a proper system of surface drainage," which is of course what is wanted.

17. There is another serious disease-cause which requires notice here, although it relates to cholera. It is stated as follows:—"One of the greatest defects in the station is the total want of proper drainage "from the town of Secunderabad. At present the whole of the sewage runs by the back of the staff "lines into the Husain-Saugor tank, by which the health of the neighbourhood is being fast ruined. "In February the General was attacked with cholera, and in August the wife of the European "whom he left in charge of his house, died of cholera; a lady, two days after, returning from the "hills, was attacked and died of cholera." The stench arising from the drain is sometimes overpowering. In the same station there are also said to be "various gravel pits, which, on rain falling, "get filled with water, which becomes putrid as evaporation proceeds." It does so because of the amount of filth it carries with it from the surface and subsoil of the station, of which the putrescence is an index.

We are glad to learn from the Adjutant-General's remarks that this subject of the Secunderabad drainage has been brought to the notice of the Resident at Hyderabad, "and it is hoped that measures will be taken to remedy it."

18. The fever group, taken together, yielded the following admissions and deaths in 1882:—Eruptive fever, 14 admissions, of which 9 were from small-pox, and one death from the latter disease. Continued fevers, 531 admissions, including 94 from enteric fever, of which, as already stated, 29 proved fatal. Paroxysmal fevers, 853 admissions and three deaths.

Including cholera, the whole fever group gave an admission-rate of 134·38 per 1,000 and a death-rate of 4·14 per 1,000 of which 2·74 per 1,000 was due to enteric fever, leaving 1·4 per 1,000, as the year's death-rate from all other fevers.

The year 1883 was not one of the fever years among European troops, for the admission-rate was 47·46 per 1,000 lower than in 1882, although the greater prevalence of enteric fever had added 0·81 per 1,000 to the fever death-rate. The admission-rate from fevers on a ten years' average, 1873–1882, had been 263·03, and the average death-rate 1·73 per 1,000.

In 1883 the purely febrile diseases gave an admission-rate of 130·39 per 1,000. The years 1878 to 1880 were epidemic years, and yielded admission-rates of 340·8, 397·3, and 450·6 per 1,000, but the year 1883 yielded the highest fever death-rate of the entire 11 years.

19. *Cholera.*—Separating this disease from the febrile group, it is stated to have occasioned 19 cases and 10 deaths. The latter took place at the following stations:—

Stations.	Deaths from Cholera.
Bellary	1
Secunderabad	5
Kamptee	3
	9
On the march	1

The enteric fever stations were the stations which yielded the deaths from cholera in 1883, and the sanitary details already given for these stations are sufficient to indicate the probable local predisposing conditions of both diseases. It is worthy of remark, however, that one enteric fever station, Bangalore, escaped cholera.

We have no details as yet as to the extent to which cholera prevailed in the vicinity of any of the stations, so that the history is incomplete.

20. The only other death-causes which appear to require notice are dysentery and liver diseases. The former yielded three deaths, one at Kamptee and two at Rangoon. Hepatitis and abscess of the liver caused 17 deaths. Four of these took place at Madras and St. Thomas' Mount, three at Cannanore, one at Bangalore, one at Secunderabad, two at Kamptee, four at Rangoon, one at Tongboo, and one on the march.

21. These details appear to be sufficient for our purpose of tracing the relation of the health of troops to sanitary and personal conditions for the year under review, and the facts taken as a whole warrant the following conclusions:—

(1.) Making allowance for the fact that 1883 was not an epidemic year from fever, the history of the Madras European Army shows that its health has undergone great improvement concurrently with advances which have been made in sanitary works, in general administrative measures, and apparently in improved personal habits of the men.

(2.) As shown by the mortality from enteric fever and cholera, Kamptee, Bangalore, Secunderabad, and Bellary are the stations chiefly instrumental in keeping up the death-rates at present.

(3.) With regard to the three first of these stations, there are sufficient facts in the present Report on which to urge strongly the necessity for proceeding without further delay to provide Bangalore with good water. The new points raised in the Report as to the state of the Ulsoor tank in dry weather should be further submitted to skilled inquiry.

(4.) The facts regarding Secunderabad point to the necessity for more active sanitary supervision of all places frequented by troops, or for keeping the troops out of them. The question of drainage is also one of urgency.

(5.) No satisfactory account has yet been given of the reasons why Kamptee is so subject to enteric fever and cholera. The data in the present Report appear to point to undrained subsoil as a not improbable cause, which, at all events, might be inquired about.

Lastly,—The present Report has pointed out the stations to which high death-rates are due, and it would be most advisable to concentrate effort on their improvement.

10th April 1885.

No. 16.

Memorandum of the Army Sanitary Commission on the Medical History of the European Troops in the Bombay Command for 1883.

1. This Report, as its name implies, is almost exclusively devoted to departmental details, and, except in the statistical portions of it, there is little calling for remark.

The sanitary details regarding the more important stations have lately been fully described by the Sanitary Commissioner with the Government of Bombay, and his reports are, we believe, under consideration by the executive authorities, in whose hands the important questions which have been raised by Mr. Hewlett may be safely left. On some practical sanitary points there are differences of opinion with him in the present report, which are attended with obvious disadvantages to the public service. But a course of proceeding suggested further on for avoiding such differences would apparently be the fairest for all parties.

2. The outward-bound trooping service during 1883–84 was performed by 10 voyages of the usual troopships and by a company's steamer.

The following numbers arrived at Bombay during the season:—

Officers	635
Ladies	124
Children	101
Men	12,392
Women	433
Children	535
Female servants	31

The earliest arrival at Bombay was on the 22nd October 1883. The latest was on 5th April 1884; but by the beginning of February, which is about the latest safe period for arrival in India, the whole of the troops had arrived, except 151 officers and 3,083 men.

3. During the outward voyages, which may be taken at about a month's duration, there were 1,229 admissions to hospital from among the troops, of which 321 were for primary syphilis, 39 for secondary syphilis, and 271 for gonorrhœa and its consequences. The men are all supposed to have gone on board free of disease, and they had furnished, nevertheless, 631 admissions from different forms of venereal diseases, or more than half the admissions from all causes during a voyage of about a month's duration.

4. There were four deaths during the voyage, two of these were from drowning, one from rheumatism, and one from sunstroke. Among the admissions there were 197 cases of itch, an occurrence requiring separate mention.

5. Of 535 children embarked, 12 died during the voyages, and 7 of the deaths took place on board the "Euphrates," which made the voyage by the Cape. These casualties resulted from the usual infantile complaints. One woman died of bronchitis. "The sanitary condition of the various troopships was good, and the accommodation sufficient."

6. The return voyages were performed by the troopships and two other steamers, the first of which left Bombay on the 31st October 1883, and the latest on the 1st May 1884, conveying with them to England the following numbers:—

Officers	467
Ladies	147
Children	188
Men in health	8,297
Women	416
Children	925
Invalids, men	1,634
„ women	137
„ children	344
Insanes	93
Convicts, &c.	12[illegible]

Of invalided men, 997 left India after the beginning of April, and would arriv[illegible] weather.

7. We shall next abstract the statistical facts bearing on the health of troops serving [illegible]ombay stations in 1883, which were as follow:—

Average strength, 11,183.

Admissions	13,679	=	1223·2 per 1,000.
Constantly sick	631·87	=	56·50 „
Deaths	116	=	10·37 „
Invalids for change	332	=	37·65 „
Invalids for discharge	89		

These ratios show improved and improving health. The preceding four years' average ratios were for—

Admissions	1835·5 per 1,000.
Deaths	16·67 „
Invalids	49·79 „
Constantly sick	65·65 „

The most important admission causes were the following:—

	Admissions.
Paroxysmal fevers	4,234
Continued fevers	592
Digestive system	2,038
Primary syphilis	691
Secondary syphilis	224
Gonorrhœa	1,073
Sequelæ of do.	180
	9,032

To fevers, venereal diseases, and diseases of the digestive organs, 9 out of every 13 admissions to hospital were due.

8. The following were the death causes of the year:—

Diseases.	Deaths.
Small-pox	1
Enteric fever	15
Remittent fever	8
Other fevers	2
Cholera	9
Tubercular diseases	4
Other constitutional diseases	4
Nervous diseases	17
Circulatory diseases	7
Respiratory diseases	11
Digestive	13
Others	1
Poisons	3
Injuries	10
Total	111

Of the three deaths entered under the head of "poisons," one was occasioned by alcohol, one by delirium tremens, and one by stings of insects.

The last two death causes in this list do not properly belong to causes connected with the stations. They represent more or less constant quantities, and the time seems to have arrived for separating in

all the armies those deaths due to locality from deaths due to extraneous causes, and this is the more necessary because violent deaths would otherwise account for an increasing percentage of the mortality, while the deaths due to preventible disease were diminishing with the advance of sanitary work. Apart from this added ratio, the disease deaths in 1883 were only 8·75 per 1,000 for the Bombay European Army, and our present object is to try whether this disease death-rate cannot be further reduced by sanitary work at the stations. Deaths due to drink and to accidental causes, or to suicides, belong rather to the sphere of general army administration than to that of the sanitary administration, and, while the latter ought to be fully credited for the result of its proceedings, it should not be charged with deaths over which it has no control.

9. If the present disease death-rate were to become an average rate, the sanitary administration, instead of confining its attention mainly to reducing the mortality, would have to take up the question of inefficiency, as this is represented by the admissions, daily sick, and invaliding, and to [illegible] their reduction by dealing with the stations individually. No doubt this is to a certain [illegible] at present, but when an army presents a death-rate no higher than that due to the same [illegible] life, and yet has too many men not in the ranks but in hospital, it seems to be time [illegible] part of the question and to deal with it separately. Of course these remarks are [illegible] knowledge that all the elements of inefficiency are subject to considerable variations [illegible] the same stations, but there are stations which bear the stamp of unhealthiness [illegible]

[illegible] as an example. The average strength of troops at this station in 1883 was 621. [illegible]on-rate was 1471·8 per 1,000. The death-rate was 16·10 per 1,000. The previous 10 [illegible]erage had been for admissions 1877·9, and for deaths 17·44 per 1,000. Now it is obvious that there must have been something wrong in this case. But we must deduct from the admission-rate what may be called personal diseases, namely, those of the venereal type, which in 1883 accounted for no fewer than 202·6 per 1,000, and there would be left 1269·2 per 1,000, while we find that of this high rate no less than 389 per 1,000, or nearly a third of the whole, were due to fevers. Of these fevers 25 cases were diagnosed as "enteric" fever. The sanitary questions connected with these Karachi fevers, and with the general degradation of the health of troops, have been discussed year after year, and have been specially reported on by Sanitary Commissioner, Bombay, with the result that probably the safest and most economical way of dealing with the whole question would be to remove the troops to Ghizree.

With the well-known facts about Karachi before us, and which we have often reported on for the information of the executive authorities, what can be said about a statement such as the following in the present Report? "As regards the outbreak of this enteric fever at Karachi, no direct cause in "point of sanitation, &c. has been found, but the Medical Officer in charge of the station hospital is "of opinion that the rainfall has some connexion with this fever, and that it occurs some days after "rainfall." Of course the practical conclusion from such a statement must be that, as the executive authority cannot control the rainfall, nothing can be done. This is one of the cases to which we alluded at the commencement of the present Memorandum, and the contradiction might have been avoided by a brief conference with the Sanitary Commissioner before drawing up the Report.

11. Another case is even of more administrative importance. The Sanitary Commissioner for Bombay, Mr. Hewlett, was specially directed to report on the sanitary condition of Nasirabad, and his report gives a very complete account of the whole locality, indicating clearly what ought to be done with the question, and advising certain improvements in details. This report had somehow fallen into the hands of the Surgeon-Major at the station, and he, while concurring with some of Mr. Hewlett's proposals, objects to others. We are not concerned with the question which officer is right, although we have little doubt on the subject in any matters of sanitary experience, but the very obvious question presents itself as to whether this method is the best possible for dealing with a large and very important question, and whether it would not have been better to follow our home example in such cases in discussing the details with the officers on the spot, who, it must be remembered, are responsible before reports are finally completed. Reports of specially qualified officers, when sent in, are intended to afford materials for enabling the executive authority to arrive at practical conclusions, and ought never to be subject to contradictions such as these.

12. The extent to which enteric fever prevailed at the Bombay stations in 1883 is shown in the next abstract, and we have added the cholera mortality:—

Stations.	Enteric Fever.		Cholera.	
	Cases.	Deaths.	Cases.	Deaths.
Colaba	3	2	—	—
Deolalee	1	—	3	2
Aden	4	—	—	—
Karachi	25	2	—	—
Poona	3	2	2	—
Ahmednagar	5	1	5	4
Mhow	2	2	1	—
Nasirabad	1	—	2	1
Indore	3	1	1	1
Deesa	1	—	—	—
Quetta	13	5	—	—
Total	60	15	14	8

These figures show a mortality of 25 per cent. of the cases of enteric fever. Excluding a fatal case of cholera on the march, there were 14 cases and 8 deaths from cholera at these enteric fever stations, and these two epidemic diseases may be safely assumed as indices of the sanitary defects at them. Mr. Hewlett has in his reports given the results of special local inquiries made by him at several of them, and in our Memorandum on his Report on Bombay Presidency for 1893 we have abstracted his description of the barracks at Ahmednagar, which fully accounts for the occurrences in the preceding table.

13. At certain stations the liability of troops to fevers generally is much greater than at others. Thus, for example, Nasirabad yielded a fever admission-rate of 1,042·4 per 1,000, Neemuch of 1,032·4, Indore of 1,043·4, Mhow of 958·8, Baroda of 755·9, and Asirgash of 6·64 per 1,000. And at the other extreme of the scale, we have Belgaum yielding 99·1 per 1,000, Kolhapur 20·4, and Khandala 23 per 1,000. There are, of course, reasons, general or local, for these differences, and they can be discovered, and as far as possible removed by the sanitary service. As regards several of the feverish stations, the causes and remedies are both known.

As we have already suggested, it is by pursuing sanitary work in this direction that improved army efficiency is to be sought for, rather than in lower death-rates. As it is thoroughly recognized that fever, of all diseases, affects the stamina of troops most, we expect greater energy on the part of executive authorities in dealing with its causes.

14. *Venereal Diseases.*—These diseases prevail to a very considerable extent in the Bombay Army, although the proportion is apparently less in places where there are lock hospitals.

The following have been the admission-rates per 1,000 from primary syphilis and gonorrhœa (which may be assumed as showing the relative amount of infected cases), and excluding all secondary cases, during the last five years:—

Years.	Admissions per 1,000.	
	With Lock Hospitals.	No Lock Hospitals.
1879	207	284
1880	207	256
1881	161	284
1882	129	330
1883	133	278

These rates are favourable to the effects of lock hospitals, and it might be advantageous to compare the procedure at the Bombay lock hospital stations with that followed in other Presidencies where the results have not been so satisfactory. But, at the same time, all the facts of the case should be stated, otherwise there may be grounds of fallacy. On this account it appears to be desirable to quote the following annual totals, showing the admission-rate per 1,000 from all venereal diseases, primary and secondary, in the Bombay Army, since 1872, from Dr. Cuningham's Report:—

Years.	Admissions per 1,000 from all Venereal Diseases.	Years.	Admissions per 1,000 from all Venereal Diseases.
1872	176·4	1878	254·8
1873	215·6	1879	296·8
1874	202·2	1880	261·6
1875	200·2	1881	245·2
1876	207·8	1882	229·5
1877	293·1	1883	225·1

If we assume what may be called the general venereal infectedness of the Army, and apply the test of time to its amount, as is done in this abstract, it would appear as if the lock hospital comparison would have to be modified in its value. So that, even admitting the apparent falling off in primary admissions at lock hospital stations, the total amount of disease, unless otherwise accounted for, would apparently have increased since these hospitals were introduced. The fact merely shows the necessity of taking all the circumstances into account before arriving at a conclusion as to the value or otherwise of the present police system.

15. The most satisfactory statements made in this Report are those showing the improved health of all ranks in the Bombay European Army, of which the following brief statement contains the results:—

Classes.	Ratios per 1,000 Strength.			
	Ten Years.		1883.	
	Deaths.	Invalids.	Deaths.	Invalids.
Officers	13·85	83·10	5·90	61·95
Non-commissioned officers	19·07	50·58	13·59	43·05
Privates	14·27	49·41	9·94	36·92

It is impossible to overlook the significance of these figures, proving, as they do, not only what has been done, but what can still further be done, for improving the health and efficiency of the Bombay European Army. But their teaching reaches much further than to this result, for the argument is unanswerable that, if so much can be done for strangers to Indian climates and conditions of life, at least a similar result in its degree ought to be attainable for the Native population, and this, in its turn, would react on the health of every regiment in the Presidency. It is time that these violent epidemic outbursts which we have discussed in our Memorandum on Dr. Hewlett's Bombay Report should be taken in hand and dealt with. There is much to be done by the military executive before all epidemic disease causes have been removed at military stations. The causes are known, and their remedies, at least enough to justify present practical action; while, as regards the population groups, among which the troops are stationed, the causes are known, but the remedies have still to be applied by the civil authority. This deficiency, however, in no way detracts from the credit justly due to those who have brought the health standard of the Army to its present position.

Our conclusions then are:—

1. That very satisfactory progress is being made in the sanitary condition of European troops.
2. That the stational improvements advised by Mr. Hewlett, and the details supported by the opinion of the principal Medical Officer should be carried into effect as quickly as pecuniary reasons admit of.
3. That village improvements, especially of those in the vicinity of stations, should be taken in hand, and proper executive means for giving effect to them should be provided.

This will be found to be one of the most effectual methods for protecting the health of troops, especially during epidemic seasons.

6th August 1885.

No. 17.

MEMORANDUM of the ARMY SANITARY COMMISSION on REPORTS of FAIRS and FESTIVALS held within the PRESIDENCY of MADRAS during the latter months of 1883 and part of 1884.

These papers contain local reports of administrative and medical officers on the sanitary condition of places where fairs and festivals were held, together with notices of instances in which cholera appeared during the period of occupation.

The Reports give details regarding 12 festivals in 1883, and 129 in 1884. But the estimated attendance is stated only in 37 instances, and in these it amounted to 1,161,600 persons, besides the usual numbers of animals. We may safely estimate the attendance at all the fairs and festivals as about 2,000,000.

Of the 12 festivals held in 1883 cholera appeared at three.

At one of these, Karthagia, in South Arcot, 14 cases of cholera were reported from among 20,000 people; but, as there were no deaths, the diagnosis seems doubtful. At Mayavaram, in Tanjore, there were three deaths from cholera, but the attendance is not stated. At Tirupati, in North Arcot, there were six deaths from cholera from among 40,000 people. At Karthagia and Mayavaram the cleansing was reported as "insufficient," and at Tirupati "tolerable." But here the element of epidemic intensity has to be taken into account, for these three places are situated in districts which suffered most from cholera in 1883, and the epidemic was severe in the districts at the time when the fairs were held. The cholera death-rate for the whole Presidency was 1·2 per 1,000. In Tanjore it was 3·0 per 1,000. In South Arcot it was 3·1 per 1,000, and in North Arcot 1·4 per 1,000, while at the Tirupati festival the death-rate among 40,000 pilgrims was 0·15, or about a tenth part of the district rate. The facts are of importance, because this Tirupati festival, according to contagion views, has been a centre from which cholera has radiated.

We have no means of contrasting the deaths from cholera at fairs during the subsequent year, 1884, with the district rates, as these have not yet been reported. We can only discuss the facts by themselves, and these are as follow:—

In 1884 there were 129 fairs and festivals up to the dates of the Reports. At one fair cholera was in the town, but no pilgrims suffered. This town was Thai Pusam, in Madura, and its sanitary condition was reported not good. In another town, Denkanikota, in Salem district, the sanitary state of which was reported bad, cholera prevailed in town at the time of the fair, and there appear to have

been seven deaths among pilgrims. Besides these affected town examples, cholera deaths among pilgrims and other attendants took place at the following fairs:—

Locality and District.	Numbers present.	Sanitary Condition as reported.	Deaths from Cholera.
Chidambaram (South Arcot)	5,000	Not good	7
Yekadesi, Trichinopoly	5,000	Satisfactory	24
Tiruvangam "	Not stated	Not good	20
Manneargudi (Tanjore)	Not stated	Bad tank	19
Another fair (Tanjore)	Not stated	Bad tank	11
Tanjore	15,000	Insufficient	14
Tinnevelly	15,000	Indifferent	5

Including the seven deaths in the cholera affected town, Denkanikota, there were thus 97 deaths at these eight fairs. The history, however, as already stated, is incomplete without a knowledge of the local incidence of cholera in the districts during 1884; but the history of cholera during December 1883 appears to show that, in the districts where cholera affected fairs were held in 1884, cholera had passed over in considerable intensity from the preceding year's epidemic. Thus we find the cholera deaths in December 1883 for these districts to have been,—

	Cholera Deaths.
South Arcot	1,942
Trichinopoly	1,472
Tanjore	2,319
Tinnevelly	4,372
Salem	1,194

These districts which yielded all the festival deaths of 1883–84 were those in which the mortality from cholera was by much the greatest in December 1883.

It is highly probable, therefore, that local cholera intensity was a factor in these festival outbreaks, besides what may have been due to bad sanitary condition.

The facts may be summed up as follows:

Fairs and festivals, 1883–84	141
Escaped cholera deaths	131

Cholera appeared at 10. Arranged according to districts, the attacked localities of 1883–84 were situated as follow:—

Districts.	No. of Fairs.	No. where Cholera appeared.	Deaths from Cholera, 1883–84.
North Arcot	2	1	6
South Arcot	3	1	7
Tanjore	15	4	37
Trichinopoly	2	2	44
Salem	22	1	7
Tinnevelly	5	1	5
Total	49	10	106

The cholera outbreak of 1883–84 among pilgrims and attendants at fairs was hence confined to 10 fairs out of 49 which took place in six districts where cholera prevailed severely in 1883, and probably in part of 1884. It is necessary to bear this last fact in mind, because of the risk always present of blaming pilgrimages for spreading cholera, instead of blaming the bad sanitary condition of towns and districts for pilgrim attacks.

The remaining 131 fairs and festivals which escaped the disease altogether took place in 12 districts. In describing the sanitary condition of the places where these festivals were held, the terms "good" and "sufficient" are applied to nearly all of them; but it must be stated that the mortality from cholera among the population of these districts where the festivals escaped was very much less in 1883, at least, than it was in the districts where they suffered.

Taking the aggregate pilgrim population at two millions, the cholera death-rate among them would be 0·053 per 1,000, while the Presidency rate, on a five years' average, was 0·6 per 1,000, and for 1883 double this amount, or 1·2 per 1,000, or 23 times the amount of the pilgrim losses.

The general result of this experience is, that, although much life has been saved at these festivals, more vigour should be displayed in rooting out the known predisposing epidemic causes in the towns and villages of Madras Presidency. A study of these Reports shows that this can be done by simple and well-devised regulations under supervision for ensuring constant cleansing and keeping clean. This, with simple surface drainage and improved dwellings and protection of water sources, will do far more for the public health in small towns and villages than the execution of costly permanent works where trust is reposed in these for safety, and cleanliness is neglected.

REPORT.

I.—EUROPEAN ARMY OF INDIA.

Sickness and mortality in 1884.

The health of the European Army of India in 1884 was not so favourable as in the previous year. The admission-rate per 1,000 of an average strength of 54,996, according to the report of the Sanitary Commissioner with the Government of India, was 1,513 against 1,336 in 1883, the daily sick-rate 67 or 4 per 1,000 in excess of 1883, and the mortality 12·56 against 10·88. The loss to the army on account of invaliding was 32 per 1,000 or nearly 1 per 1,000 less than in 1883, making a total loss from death and invaliding of over 44 per 1,000, a ratio identical with that of the previous year, but 18 per 1,000 less than the average loss of the ten-year period 1870-79.

The following statement shows the sickness and mortality among the British troops of the three Presidency armies and of all India for 1884 and the previous year:—

Presidency.		Average Strength.	Ratio per 1,000 of Average Strength.		
			Admissions into Hospitals.	Daily Sick.	Deaths.
Bengal	1883	34,079	1,463	66	11·21
	1884	33,486	1,662	70	11·68
Madras	1883	10,498	1,013	59	10·19
	1884	10,785	1,109	57	8·53
Bombay	1883	10,948	1,249	57	10·50
	1884	10,725	1,455	65	19·39
India	1883	55,525	1,336	63	10·88
	1884	54,996	1,513	67	12·56

As will be seen from the above, sickness was most prevalent among the Bengal troops, while in point of mortality the Bombay portion of the army showed the worst results, which was due chiefly to the high cholera death-rate among the troops serving in Southern Afghanistan. The Madras troops were the most healthy, and the mortality among them (8·53 per 1,000) was the lowest on record.

The chief causes of admission into hospital in the Bengal and Bombay armies were malarial fevers; in all three Presidencies the ratios were in excess of the previous year, especially in Bengal, where the admission-rate rose from 486 per 1,000 of average strength to 683. Among the Madras troops malarial fevers caused an admission-rate of 166 per 1,000, being an increase of 38 on the previous year; and in the Bombay Presidency the admission-rate under this head was 504 per 1,000 against 436 in 1883. Venereal diseases, as usual, were a prolific source of inefficiency among the European troops, especially in Madras, where they headed the list of the causes of admission. As regards mortality, enteric fever again comes first, the death-rate for the entire army from this disease being 2·74 per 1,000, an increase of 0·34 on the previous year. Cholera also gave rise to a higher death-rate, viz. 1·95 against 0·92 in 1883, which was mainly due to the prevalence of the disease in the portion of the Bombay Army serving in Southern Afghanistan. But for this outbreak of cholera in Afghanistan the cholera mortality would have stood at 1·23 per 1,000.

Of the six groups of stations in Bengal, sickness was more prevalent than in 1883 in Bengal Proper, Meerut and Rohilkund, Agra and Central India, and Punjab, the exceptions being the Gangetic Provinces and Oudh group and Hill stations, and in all groups malarial fevers and venereal diseases were the chief causes of sickness. The same four groups also recorded a higher mortality, but the ratios of 1884 were in all cases below the average of the twenty year period 1860-79. In all groups excepting the Hill stations enteric fever gave rise to the highest proportion of deaths; the Agra and Central India group recorded the highest ratio from this cause, viz., 7·51 per 1,000, the next highest occurred in Meerut (4·19), Gangetic Provinces (3·96), and Lower Bengal (3·18). Cholera was more fatal in the Meerut and Gangetic Provinces groups, with death-rates of 4·19 and 3·17 respectively; it was less fatal in the Agra (1·75) and Bengal Proper (1·06) groups; while the Punjab and

Hill stations groups were exempt from the disease. The next diseases causing the largest proportion of deaths were hepatitis, respiratory diseases, and dysentery.

In individual stations of an average strength exceeding 200, which were occupied throughout the year, the highest admission-rates were recorded at Delhi (4,828 per 1,000), and Meean Meer (3,554); six other stations had ratios over 2,000 per 1,000. The highest mortality of any such station was recorded at Quetta, viz., 38 per 1,000 against a previous 10 years' average of 13·17, Hyderabad in Sind followed with 32·68, and at five other stations the death-rates varied between 20 and 31 per 1,000.

In the Hill stations of Bengal the troops, numbering 9,244, enjoyed better health than in 1883, the admission-rate having fallen from 1,454 to 1,201, while the death-rate fell from 6·33 to 5·91 per 1,000, which was the lowest on record since 1870.

Among the troops comprising the Rajputana, Malwa, Sind, and Aden group, the general health was on the whole good, though both the admission and death-rates were in excess of the previous year, but below the decennial averages of 1870–79. Of an average strength of 4,464 the admissions to hospital were in the ratio of 1,548 against 1,502 in 1883, and the death-rate 12·77 as compared with 8·32. The chief causes of death were enteric fever (2·02), apoplexy and sunstroke (1·79), cholera (1·12), and hepatitis (1·12). At the two largest stations of this group, Mhow and Aden, the admission-rates were 1,799 and 1,167, and the death-rates 6·69 and 8·51 respectively.

In the Deccan and Nagpur group (average strength 7,132) there was a little more sickness than in 1883, the admission-rate having increased from 1,001 to 1,171; still it compares favourably with 1,383 the average rate of the ten years 1870–79. The death-rate was only 8·83, nearly 2 per 1,000 less than in 1883, and 5·31 below the decennial average. Enteric fever gave rise to nearly one-fourth (2·11) of the deaths, other fevers following with 1·12, and hepatitis 1·68; from cholera the death-rate was 0·42. At Secunderabad, which is the largest military cantonment in India, the admission-rate per 1,000 of an average strength of 2,394 was 1,077, and at Poona, the next largest in this group, 1,129; their death-rates were 9·61 and 9·81 respectively.

The health statistics of the troops included in the Southern India group were also favourable. Of an average strength of 4,786 the admission-rate was 1,059 against 1,126 in 1883, and a 10 years' average of 1,235; while the death-rate, 7·73, was one of the lowest on record, and considerably below the average. The most fatal disease was cholera, which contributed 1·46 to the total mortality, while enteric fever, apoplexy and sunstroke, and hepatitis each contributed 1·04. Of the seven stations in this group, the two largest, Bangalore and Bellary, recorded admission-rates of 1,026 and 963, and death-rates of 4·07 and 7·15 respectively.

The average strength at the four stations in the British Burma group was 1,785; here the admissions were higher than usual, being in the proportion of 1,190 per 1,000 against 980 in 1883, and 1,092 the last decennial average; on the other hand the mortality was low, namely, 7·28 against 10·00 in the previous year, and a 10 years' average of 17·32. There were no deaths from enteric fever in this group; the chief causes of mortality were dysentery (1·68), hepatitis (1·12), and phthisis pulmonalis (1·12). In Rangoon, which is the largest station, the admission-rate was 1,586, and the death-rate 12·43 per 1,000, both ratios being greater than in 1883.

Among the small force of 757 troops located in the Hill stations of Madras and Bombay during 1884 the admission-rate rose from 1,059 per 1,000 in 1883 to 1,531, but the death-rate declined from 8·63 to 5·28, which was little more than a third of the average mortality of the 10 years 1870–79.

During the year 1,441 men, belonging mainly to the Bombay Army, were stationed in Southern Afghanistan, and among them the admission-rate was 2,056 per 1,000, and the death-rate 68·70, thus comparing most unfavourably with the Bombay Army as a whole. Malarial fevers were the chief causes of admission, but cholera gave rise to the greatest mortality, viz., 27·07, enteric fever following with 7·63, other fever 6·94, respiratory diseases 6·25, apoplexy and sunstroke 4·17, and dysentery 4·17, all being much higher than in the preceding year.

Cholera.

Cholera was more prevalent in the European Army of India in 1884 than in the previous year, the number of cases having increased from 82 to 150, and the deaths from 51, or 0·92 per 1,000 of average strength, to 107, or 1·95. The disease was of a more virulent character than usual, as is shown by the fact that the per-centage of deaths among those treated was 71·33 against 62·20 in 1883, and 62·24 in 1882. Of the total cases, 67 occurred in the Bombay army, of which 52 were fatal, but these unfavourable results, as already stated, were mainly owing to the prevalence of the disease among the troops stationed in Southern Afghanistan, where there were 49 cases and 39 deaths. In the Bengal Army, also, there was a greater number of cholera cases

under treatment than in 1883, namely, 71 against 48, while the fatal cases rose from 32 or 0·24 per 1,000 of average strength to 45 or 1·34. There were but 12 cases in the Madras Army, and of these 10 or 0·93 were fatal, the same number as in 1883.

Small-pox was less fatal among the European troops. There were in all 78 cases against 105 in 1883, and 8 deaths or 0·14 per 1,000 against 9 or 0·16. Bengal contributed 6 of the deaths and Madras and Bombay one each. Small-pox.

Intermittent fever was very prevalent during 1884, and gave rise to an admission-rate of 487 per 1,000, against 359 in 1883. This increase, however, was not accompanied by an increased mortality, for in both years there was but one death under this head. Remittent and continued fevers were also more prevalent, the admission-rate for the army as a whole having increased from 49 per 1,000 in 1883 to 60 in 1884, and the death-rate from 0·41 to 0·62 per 1,000. Still the admission-rate compares favourably with 162, the last decennial average. The increase mainly occurred in the Bombay Presidency, where the admissions per 1,000 rose from 31 in 1883 to 85, while in Bengal they fell from 62 to 60, and in Madras they rose from 30 to 36. Fevers.

Enteric fever continues to increase among the European troops. During 1884 there were 644 cases, equal to 11·7 per 1,000 of average strength, against 429 cases, or 7·7 in 1883; the mortality also rose from 133, or 2·40 per 1,000, to 151 or 2·74. All three Presidencies contributed to the increase in admissions, but the increase in mortality was confined to Bengal and Bombay, where the death-rates rose from 2·52 to 3·31 and from 1·55 to 2·05 per 1,000 respectively, while in Madras the mortality fell from 2·86 to 1·67. The statistics of newly arrived regiments in regard to this fever show most unusual results, the death-rate being only 2·33 of the total mortality against 8·95 in 1883. In other respects also the health of these troops was better than that of soldiers of longer residence in India. The year's statistics again point to the conclusion that young and unacclimatised soldiers are particularly subject to this fever. Among men under 25 years of age, the death-rate from this cause was 4·61 per 1,000, while between the ages of 25 to 29 it was 1·83. The relationship between enteric fever and length of service was also well defined, for while the mortality among troops during their first and second year's residence was 5·47, among those in their third and sixth years it was only 1·55. Enquiries were again made by medical officers during the year with the view of tracing the causation of the disease, but it is stated that in the great majority of cases no clue whatever could be found in any local insanitary conditions. The Army Sanitary Commission notice that the admission-rate from this fever in the Indian army (11·7 per 1,000) was ninefold that of the Home Army (1·3), and that the Indian death-rate (2·74) was twelvefold that of the Army at home (0·24). "The "contrast," they say, "is otherwise of importance, because it shows that, as both the "Indian and Home armies contain many young men, there must be some other factor "besides youth to account for this difference of liability to fatal fever. No doubt "heat and other climatic influences add to enteric fever liability in India, but the "amount of this liability cannot be estimated until we shall have freed Indian stations "from those local fever causes which we know from home experience to be connected "with liability to enteric fever in the colder climates of home stations. There is "plenty of evidence to show that these local causes are closely related to the subsoil "conditions under and around barracks in India, and that it would be very advisable "to deal practically with at least one enteric fever station on this ground. There is "also experience to show that enteric fever stations are liable to outbreaks of cholera, "and the relation of local insanitary conditions to the latter disease is proved by the "arrest put on it by the removal of troops. It is even not at all improbable that "change from an enteric fever station into a healthy camp might be of use."

Venereal diseases yielded an admission-rate of 294 per 1,000 against 270 in 1883, Each of the three Presidency armies shared in the increase, particularly Bombay, where the admissions rose from 218 per 1,000 in 1883 to 292. Madras, again, recorded the highest rate, viz., 307 against 289, and among the Bengal troops the rate was 291, or 10 per 1,000 higher than in 1883. In spite of police and lock hospital precautions, the admissions from these diseases continue to increase, and for the whole army have risen from a 10 years' average (1870–79) of 203 per 1,000 to 294 in 1884. "The whole subject," the Army Sanitary Commission state, "appears to be surrounded with insurmountable difficulties, for in every Government "the disease has advanced in the face of every means of prevention which have "been adopted." Venereal diseases.

Invaliding.

The invaliding rate for the European Army of India as a whole was 31·74 per 1,000 of strength against 32·66 in 1883. The proportions contributed by each of the Presidencies were remarkably even, that of Bengal being 31·84, Madras 31·82, and Bombay 31·36. Of the 1,757 men invalided, 41 per cent. were for discharge as unfit for further service, which is a higher per-centage than for the three previous years, and was due entirely to the large increase of 12 per cent. (33 against 21) in the Bombay Army, for in the Bengal Army the ratio was the same (45) as in 1883, and in Madras it fell from 40 to 36. In each Presidency the chief causes of invaliding were anæmia, debility, hepatitis, and phthisis pulmonalis. Young men under 25 years of age yielded the highest per-centage of those invalided, viz., 38·70, which was larger by 2·15 than in the preceding year. As regards the effect of length of residence in India upon invaliding, the largest per-centage (49·97) occurred, as usual, among men of two to five years' residence; among men under two years' service the per-centage was 24·19 against 18·94 in the previous year.

II.—NATIVE ARMY.

In the Native Army of India, the results of 1884 were on the whole favourable. Of an average strength of 114,827 the admissions into hospital were in the ratio of 1,042 per 1,000 against 923 in 1883, the daily sick 33 against 31, but the death-rate fell from 11·76 to 10·50, thus showing that the type of sickness in 1884 was of a less severe character. Including deaths among men absent from their regiments, the mortality for the year was 12·22 per 1,000 against 14·31 in 1883. Sickness and mortality in 1884.

The sickness and mortality of the various portions of the Native Army are given in the following Table:—

		Average Strength.	Ratio per 1,000.			
			Admissions.	Daily Sick.	Deaths.	Total Deaths, including Absentees.
Bengal Native Army	1883	40,932	985	32	10·55	13·98
	1884	40,850	1,198	35	10·97	12·56
Madras ditto	1883	27,703	737	27	10·76	12·51
	1884	28,050	836	31	10·02	11·82
Bombay ditto	1883	23,576	994	35	12·81	14·96
	1884	23,373	1,153	38	12·96	14·35
Central India Regiments	1883	5,197	595	19	7·89	10·16
	1884	5,082	644	20	5·90	7·23
Punjab Frontier Field Force	1883	10,438	1,419	45	21·46	23·35
	1884	10,458	1,262	36	10·71	14·00
Hyderabad Contingent	1883	6,983	572	20	7·59	9·31
	1884	7,014	574	19	4·56	5·30
India as a whole	1883	114,830	923	31	11·76	14·31
	1884	114,827	1,042	33	10·50	12·22

As will be seen from the above, in all three Presidencies there was an increase in the admission and daily sick rates, but a decrease in the total mortality compared with the previous year. Malarial fevers were, as usual, the chief causes of sickness, and accounted for 503·2 of the total admission-rate against 387·4 in 1883. Respiratory diseases caused the greatest mortality, viz., 2·97 of the total death-rate, against 3·91 in 1883, "a fact which," the Army Sanitary Commission observe, "suggests inquiry "regarding clothing and shelter, whether both are suited to the diverse climates where "the Native Army serves." The next highest mortality (1·80 per 1,000) resulted from fevers, and next in order came cholera (0·71).

In the Bengal Command sickness and mortality were more prevalent than in 1883, still, on the whole, the health of the troops was more favourable than usual. As shown above, the admission-rate was considerably greater, but the rise in mortality was very inconsiderable. Intermittent fever was the chief cause of sickness, the admissions from which rose from 398 to 595 per 1,000 of strength. Bowel complaints also caused more sickness, the ratio of admissions having risen from 67 to 99 per 1,000. Respiratory diseases were again the chief death causes, but it is satisfactory to learn that the mortality under this head continues to decline, namely, from 4·50 per 1,000 in 1882 and 3·20 in 1883 to 2·77 in the year under notice. Fevers, on the other hand, showed a considerable increase in mortality, from 1·32 to 2·40 per 1,000. Cholera and bowel complaints were also more fatal, cases of the former having risen from 38 to 41, and the deaths from 23, or 0·56 per 1,000, to 29, or 0·71. Bengal Native Army.

The principal statistics of the several groups of the Bengal Army were as follows :—

		Average Strength.	Ratio per 1,000.		
			Admissions.	Daily Sick.	Deaths.
Bengal Proper and Assam	1883	6,100	1,408	46	16·23
	1884	5,882	1,367	42	14·61
Gangetic Provinces	1883	7,315	970	34	8·17
	1884	7,500	929	32	6·00
Rohilkund and Meerut	1883	5,813	978	36	11·53
	1884	5,180	1,188	43	10·62
Agra and Central India	1883	5,028	906	31	5·77
	1884	4,722	1,312	37	7·84
Punjab	1883	15,279	830	24	10·80
	1884	14,728	1,083	29	8·49

In every group fevers were the chief causes of sickness, and only in the Bengal and Assam group were they less prevalent than in 1883. Bowel complaints occasioned more admissions in every group, and respiratory diseases were on the whole as prevalent as in the previous year. As regards mortality, the ratio of 1883 was exceeded only in the Agra and Central India group, which registered a death-rate of 7·84 in 1884 against 5·77 in 1883. Cholera was present in all the groups but the Punjab; in the Agra and Central India group the death-rate under this head was 1·06 per 1,000 against none in the preceding year, and in the remaining three groups the mortality was less. Fevers were more fatal in all the groups but the Gangetic Provinces, where there was a slight reduction. Bowel complaints gave rise to a higher mortality in the Rohilkund and Meerut, Agra and Central India, and Punjab groups than in 1883; in the latter group, however, the increase was very slight. The mortality from respiratory diseases was in all cases less than it had been in 1883, especially in the Punjab, where the ratio fell from 4·97 to 2·78.

Of individual stations in the Bengal Command occupied throughout the year, Dhuki and Gumbuz, with an average strength of 278 men, recorded the highest admission-rate, namely, 3,194 per 1,000, and 12 others recorded rates varying from 1,500 to 2,000. The highest death-rate (68·35) also occurred at the above station, and four others had death-rates exceeding 20 per 1,000. "It is not at all unlikely," the Army Sanitary Commission observe, "that skilled sanitary inquiry would find some "reason for these rates."

There was a satisfactory reduction in sickness and mortality among the troops comprising the Punjab frontier force. The chief causes of sickness were, as usual, fevers, which contributed more than one-half of the admissions; respiratory diseases came next, but with a much smaller ratio than the previous year, namely, 72·5 per 1,000 against 109. Altogether there were 112 deaths in this force, of which 54, equal to 5·16 per 1,000 of strength, were from respiratory diseases. In the preceding year the deaths from this cause numbered 148, or 14·18 per 1,000. This force was exempt from cholera during the year.

The health of the Central India Regiments was again very favourable. Sickness was somewhat more prevalent, compared with 1883, but the mortality, which was very low, fell from 7·89 to 5·90. The actual number of deaths was 30, of which 12 resulted from respiratory diseases. There was only one cholera case in this force and this proved fatal.

The statistics of the Hyderabad Contingent were, as usual, extremely favourable. The admission-rate was identical with that of 1883, but the death-rate (4·56) was 3 per 1,000 less. Respiratory diseases were the chief causes of mortality and yielded 9 of the total 32 deaths. Cholera was fatal in two out of three cases.

Madras Native Army.

The health of the Madras Native Army as a whole was again very favourable. Sickness was slightly more prevalent, the admission-rate having increased from 737 per 1,000 in 1883 to 836 in 1884, and the daily sick-rate from 27 to 31 per 1,000; but the death-rate declined from 10·76 to 10·02, or including absent deaths, from 12·51 to 11·82. Intermittent fever accounted for the largest number of admissions, and

respiratory diseases for the largest mortality, namely, 48 deaths (or 1·71 per 1,000) out of a total of 281. From cholera there were 80 cases and 41 deaths, or 1·46 per 1,000 of strength, against 173 cases and 81 deaths, equal to 2·92 per 1,000 in 1883. Fevers yielded 44 deaths, or 1·57 per 1,000, and bowel complaints 31, or 1·11 per 1,000. Small-pox cases numbered 100, but only 6 proved fatal.

The most unhealthy of the large stations in this Command was Secunderabad, which recorded an admission-rate of 1,416 per 1,000, but the highest mortality was recorded in Toungoo (22·88), and the next highest at Secunderabad (18·55). Of the 64 deaths at the latter station, 27 were due to cholera, whilst in Toungoo there were no deaths from this disease. At Bangalore, which is the largest station, the total deaths were 22, or 6·27 per 1,000, and of these two resulted from cholera.

Bombay Native Army.

The Bombay Native Army was not quite so healthy in 1884 as in the two previous years, sickness being more prevalent and the mortality somewhat greater. As in the other branches of the Indian Army, fevers stand first as causes of admission, and were in the proportion of 570 per 1,000 of strength against 399 in 1883. The deaths in hospital numbered 303, or 12·96 per 1,000, of which 105, or 4·49, were due to respiratory diseases, 42, or 1·80, to fevers, and 40, or 1·71, to dysentery and diarrhœa. Of the various portions of the Bombay Native Army, sickness was most prevalent in the stations occupied in Southern Afghanistan and the Persian Gulf. At Dhuki, Gundakindoff, and Bolan Pass the admission-rates were 4,433, 3,257, and 3,073 per 1,000 respectively. The highest mortality (42·84) was also returned from the first of these stations, respiratory diseases being the chief causes of death, and numbering 13 out of a total of 29. Amongst individual regiments, that of the 12th Bombay Native Infantry, at Pishin and its outposts, recorded the highest mortality, namely, 66·19 per 1,000 of an average strength of 753.

III.—GENERAL POPULATION.

Vital Statistics.

Registration of vital statistics in India makes but slow progress; in some few provinces there has been a marked improvement, but on the whole registration is still very imperfect. At present it is impossible to arrive at any satisfactory idea of the birth-rate, as in Bengal, with a registered population of 66,163,884, births during 1884 were registered only in 47 of the principal towns, having a population of 1,685,651. The total population under registration in eleven provinces, including Calcutta, in 1884 was 198,146,858, and the actual registered deaths numbered 5,239,218, or 26·44 per 1,000, exceeding the number of the previous year by 638,570; but then 1883 was an exceptionally healthy year, while 1884 was comparatively unhealthy, owing chiefly to an abnormal dryness in the summer, followed by excessive autumnal rains. "The "entire year's increase and more," the Army Sanitary Commission remark, "was due "solely to epidemics, and this fact affords the only clue to the required remedies. "The epidemic and local causes in India are quite well known, but up to the present "time the epidemic statistics show conclusively that little or no reduction of them has "been made by the sanitary executive, where there happens to be one."

The following table shows the mortality from the four chief diseases, and also that from all causes in the different provinces during 1884 as compared with the death-rate of the previous year:—

Provinces.	Cholera.		Small-pox.		Fevers.		Bowel Complaints.		Deaths from all Causes.		
	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000 of Population under registration.	
										1884.	1883.
Bengal, excluding Calcutta	134,421	2·03	18,533	0·28	966,228	14·60	58,576	0·88	1,378,610	20·83	18·82

Bengal.

Registration of births in Bengal continues to be confined to selected towns. In the year under review, 47 towns situated in 20 districts returned 39,640 births, equal to 23·51 of their population, which is an advance of 1·43 per 1,000 on the ratio of 46 towns in the previous year. The registered deaths for the whole province numbered 1,378,610, or 20·83 per 1,000, against 1,245,676, or 18·82, in 1883. As usual there were great diversities in the death-rates of individual districts, ranging from 10·93 in Durbhanga to 39·60 in Nuddea. "Taking the year's results as a whole," the Army Sanitary Commission remark, "they show that considerable progress is being made "with the important work of registration of deaths. The Government is quite alive "to the importance of the work, and may be safely left to do the best that can be "done with it."

From all the chief diseases more deaths were registered than in 1883. Cholera was very prevalent, and the deaths rose from 90,439, or 1·36 per 1,000, to 134,421, or 2·03. All the districts were affected, and nearly 11 per cent. of the total 227,615 villages. The disease was specially severe in the Orissa division, and considerably more so than in the other three divisions of the province. On the whole there were 17,988 fatal cases in Orissa, or at the rate of 4·95 per 1,000 of population in 20·86 per cent. of the villages against 6,631 deaths, or 1·82 per 1,000, in 8·26 per cent. of the villages in 1883. The three districts of Cuttack, Poori, and Balasore, comprising this division, returned cholera death-rates of 4·16, 3·52, and 7·79 respectively, the latter being the highest district death-rate of the year. The Army Sanitary Commission remark that

" nothing new in the history of cholera has been revealed by the experience of 1884. " It is the old history repeated year after year of great numbers of population groups " scattered over the surface of Bengal living under very bad sanitary conditions and " a cholera epidemic, whence coming no one knows, but swooping down in a most " irregular manner on certain of these groups, and leaving others of them until a " future season, and the practical conclusion is simply that had these attacked groups " been in a healthy condition they would have almost, if not altogether, escaped " the epidemic of 1884." One noteworthy feature in the cholera history of the year was the exemption of fairs from the disease. Only in a very few instances did cholera manifest itself, which was attributed to the sanitary measures adopted.

Small-pox caused nearly twice as many deaths as it did in 1883, namely 18,553, or 0·28 per 1,000, against 9,714, or 0·14. As usual children were the chief sufferers, no less than 72·27 per cent. of the mortality having occurred among those under 12 years of age. All the districts were affected but Darjeeling and Julpigoree, but all the deaths were returned from less than three per cent. of the total villages, the mortality being thus essentially local in its incidence.

The fever mortality was the greatest on record, and the deaths numbered 966,238, or 14·60 per 1,000, against 913,766, or 13·81, in 1883. In 1871 the registered fever mortality stood at 169,505, or 2·56 per 1,000, and since then the deaths have steadily increased year by year, making great strides of late years, during which the Sanitary Commissioner, Dr. Lidderdale, says, more care has been accorded to registration, while no circumstances have occurred which justify the belief that the province generally is getting more feverish than before. As regards the incidence of fever in different districts, it is satisfactory to learn that the mortality has diminished very considerably in some of the worst localities, notably in Burdwan and Birbhum, where the fever death-rate has fallen from 28·86 and 27·62 respectively in 1882 to 18·81 and 19·53 in 1884. In discussing the fever history of the year the Army Sanitary Commission notice the relation of fever prevalence to sanitary defects, and while admitting that good sanitary work was done during the year, they urge that greatly increased activity is necessary, especially in villages. " If the villages are improved as they ought to be," they say, " the fatality of fever will become less year after year, but the amount of fever is " connected with the subsoil water, which in its turn is dependent on the drainage " outlets, and it will continue pretty much as it is until they, too, are made efficient."

From bowel complaints the mortality was somewhat greater and pervaded a more widespread area. The registered deaths rose from 55,270, or 0·83 per 1,000, in 1883 to 58,376, or 0·88; but it is believed that the deaths under this head are generally under-estimated.

The year 1884 was exceptionally unhealthy in Calcutta, and the deaths rose from 12,325, or 28·44 per 1,000, in 1883 to 13,256, or 30·59. The city was visited by a severe outbreak of cholera in March, April, and May, causing 1,616 deaths out of a total mortality from this disease of 2,272. Small-pox also prevailed to an unusual extent causing 478 deaths against 73 in 1883; and fever deaths rose from 3,442 to 3,618.

Madras.

The steady rise of the birth-rate in the Madras Presidency which had marked the preceding five years was continued; in fact more births were registered during 1884 than in any year since 1869, and they numbered 827,381, or 29·3 per 1,000, against 791,774, or 27·7, in 1883. By districts the birth-rates ranged from 17·1 in Nilgiris to 41·4 in Chingleput; and in all districts, excepting Godavari, Tanjore, and Tinnevelly, births were in excess of the deaths, the average excess amounting to over 6 per 1,000. The comparatively low rate in Nilgiris is attributed partly to imperfect registration, " but " I am credibly informed," the Sanitary Commissioner, Mr. Bidie, states, " that it is " common for low country natives living on the hills to send their wives to the " plains to be confined."

On the whole the year was an unhealthy one. The rainfall was above the average, but the rains were unseasonable and unequally distributed, and there was a falling off in the crops; still food grain was plentiful, and, except in some few instances, the common sort was generally cheap. The registered deaths numbered 650,335, or 23·1, against 541,930, or 19·0 per 1,000, in 1883, the increase being ascribed partly to improved registration, but mainly to the prevalence of epidemic disease. That there is still room for improvement in death registration is shown in the district death-rates, which ranged from 14·5 in Nellore and in Ganjam to 35·7 in Tanjore.

Cholera was largely prevalent during 1884, causing 75,476 deaths, or 2·67 per 1,000, against 36,284, or 1·27, in 1883. The disease was present in all the districts except South Canara, and its incidence in Ganjam, Vizagapatam, Kurnool, and the Nilgiris

was very slight. Nearly a third of the cholera deaths (23,671, or 11·1 per 1,000 of population) occurred in Tanjore district; the mortality under this head was also very high in Tinnevelly, viz., 9·6; South Arcot following with 4·4, Trichinopoly with 3·7, and Madura with 3·5 per 1,000. The high mortality at Tanjore caused much anxiety to Government. Surgeon-General Furnell, M.D., paid a special visit to Tanjore, and was of opinion that the cause of the continued prevalence of cholera in the district was most probably owing to the peculiarly contaminated water-supply upon which the people were dependent. He further believed "that the habits of the people and their "mode of life in the delta portions of the district largely contribute to the upkeep of "cholera in their midst. They live in the midst of irrigated lands, and, when the "rivers have dried up, take very little care of the drinking water supplies. While the "district is a wealthy one regarding its agricultural produce, the actual labourers "are very poor and live in wretched hovels built on a damp porous soil." In his concluding remarks on this epidemic the Sanitary Commissioner states: "The general "death-roll of the Presidency will show how much has yet to be done to protect the "people of Southern India from epidemic disease, and that our efforts must not be "confined to periods when sickness is prevailing, but be continuous and systematic. "Fortunately, too, the sanitary precautions which have been found most effectual in "warding off cholera are equally valuable for the prevention of other diseases." "In "this statement," the Army Sanitary Commission observe, "the necessities of the "case are fully recognised, and a great change would soon come over the public health "of the Presidency if sanitary work in some degree corresponded to them."

Small-pox was also unusually prevalent, and the deaths rose from 37,975, or 1·33 per 1,000, in 1883 to 61,247, or 2·17 per 1,000. This was the highest death-rate that had been recorded for 14 years excepting the famine year 1877, when there were 88,321 deaths from small-pox. Every district suffered, but the disease was most severe in Kistna and Godavari, which recorded death-rates of 6·7 and 6·3 per 1,000 respectively. Of the total small-pox deaths 11,781 occurred among children under one year of age, and 27,511 between one and 12 years, together numbering 39,292, or 64 per cent. of the total small-pox mortality. The disease was very destructive in Madras town, where the death-rate was 2·9 per 1,000 of population; so serious was the epidemic that Government appointed a special health officer as a temporary measure and passed an Act rendering the vaccination of children between the ages of 3 and 12 compulsory. No less than 74 per cent. of the small-pox deaths in Madras town occurred among children under three years of age. "As might be anticipated," Mr. Bidie states, "it raged with greatest severity in the most crowded and dirtiest "quarters of the town." In the opinion of the Army Sanitary Commission "the "history as a whole leads to two conclusions; 1st, that there is a high degree of "epidemic susceptibility to the action of small-pox, and 2nd, that much improvement "is required in the vaccination service."

From fevers the deaths rose from 203,786, or 7·04 per 1,000, in 1883 to 215,977, or 7·66, a ratio identical with the last quinquennial average. In 10 districts out of 22 the fever mortality ranged from 15·1 to 9·0 per 1,000, and in the other districts the ratios varied from 7·7 to 1·9 per 1,000. No information is given as to the local conditions accompanying these high fever death-rates, but the Army Sanitary Commission again point out that it is only by strict attention to sanitary matters that we can expect reduction. "The measures required are purely practical," they say, "and our desire for information might admit of an answer that there had been quite "enough reporting already, but far too little effective sanitary work."

Bowel complaints were also widely prevalent, and caused 28,775 deaths, equal to 1·02 per 1,000 of population, against 22,098, or 0·77 in 1883. "When cholera is "epidemic," the Sanitary Commissioner remarks, "bowel complaints are more frequent "than usual, but at the same time there cannot be a doubt that some deaths due to "cholera are registered under the milder term."

The public health of Madras city during 1884 was very unsatisfactory, the deaths having increased from 15,882, or 39·8 per 1,000 of population, to 20,123, or 50·48. Of the total deaths, 4,074 were from small-pox and 1,358 from cholera, both of which diseases were present in an epidemic form, and exceeded the mortality of the previous year by 2,117 and 1,189 respectively. The mortality among the infantile population was very great, more than a third of the total deaths having taken place among infants under one year of age, and nearly a fourth of the children in the city under five years of age died during the year.

Bombay.

Important changes in registration were made in the Bombay Presidency during 1884. The compilation of vital statistics were from the 1st of July of that year

entrusted solely to Deputy Sanitary Commissioners, an arrangement which brings them into direct communication with every village in their districts. Certain registration districts were also re-arranged, and the areas of the new districts have been made conterminous with collectorates in which the same language is spoken.

The health of the Presidency during 1884 was on the whole good, though fever was more fatal than usual, which the Sanitary Commissioner (Mr. Hewlett) attributes to the late and unseasonable rainfall. The registered births of the year amounted to 534,723, or 32·50 per 1,000, a higher ratio than in any year since 1874, and 2 per 1,000 in excess of that of 1883. By districts the birth-rates ranged from 43·43 per 1,000 in Dharwar to 16·91 in Hyderabad, thus showing the defectiveness of registration. The registered deaths fell from 420,198, or 25·53 per 1,000, in 1883 to 408,409, or 24·82, which was made up of death-rates varying between 15·55 per 1,000 in Thar and Parkar and 35·15 in Broach. It is hoped that these extreme ratios will be more equalized under the new registration arrangements. A little over 45 per cent. of the total deaths occurred among children under five years of age.

Cholera was considerably less prevalent than in 1883, the deaths having fallen from 37,954, or 2·31 per 1,000, in that year to 13,804, or 0·84, in 1884. The disease prevailed over the whole Presidency, but its incidence was very irregular, and less than 6 per cent. of the total 24,536 villages suffered. The disease was most severe in Dharwar, which returned a death-rate of 5·27 per 1,000, and in this district 33 per cent. of its villages were affected. In discussing the cholera mortality of the year the Army Sanitary Commission trace the connexion of the disease with localising influences, and they arrive at the conclusion "that the future safety of the people depends on the "extent to which efficient sanitary work is done or neglected to be done. What the "rural districts require is an efficient sanitary executive."

Small-pox accounted for 14,438 deaths, or 0·88 per 1,000 of population, against 13,404, or 0·81, in 1883. In spite of the effective vaccination service which Bombay has had for some years, small-pox appears to be on the increase, as is shown by the fact that the mortality in 1884 was more than four times as great as the average of the five preceding years, viz., 0·21. Of the total deaths, 3,723 were registered as under one year of age, and 5,413 between the ages of one and 12, about two-thirds of the mortality having thus taken place among young children.

Fever was generally prevalent over the entire Presidency, and yielded 276,989 deaths, or 16·83 per 1,000, against 266,741, or 16·21, in 1883. From bowel complaints the registered deaths numbered 35,983, or 2·19 per 1,000, which is a decrease of 691 on the mortality of the previous year. It is noticed that the same districts which suffered most from cholera, Belgaum and Dharwar, also returned the highest death-rates from bowel complaints, namely, 5·43 and 5·33 per 1,000.

The city of Bombay was more healthy in 1884 than in the previous year, the total number of deaths being 22,542, or 27·29 per 1,000, against 23,530, or 29·12, in 1883. The decrease was chiefly under cholera and small-pox, the deaths from the former having declined from 1,027 in the previous year to 576, and from the latter from 1,461 to 112. Fevers, on the other hand, caused 6,830 deaths, or 30·30 per cent. of the total mortality, against 5,903 in 1883.

Since the commencement of 1884 registration of vital statistics in the Punjab has been carried out by Civil Surgeons of districts under the orders of the Local Government. The results bear evidence of considerable improvement, the registered births having increased from 734,912, or 39 per 1,000, in 1883 to 809,912, or 42·98, in 1884. The increase was general throughout the province; only four districts recorded birth-rates below 34 per 1,000. In all the districts but six the births exceeded the deaths. A further sign of improvement in registration is revealed in the results obtained in the 49 large municipalities, the average birth-rate of which equalled 42 per 1,000. Punjab.

The year was somewhat unhealthy. The registered deaths numbered 660,298, or 35·04 per 1,000, exceeding the mortality of 1883 by 134,557, or nearly 10 per 1000. This large increase was attributed partly to improved registration, but mainly to the great prevalence of fever during the autumn months. The highest death-rates were returned from the districts of Ludhiana, Karnal, Umballa, Delhi, Ferozepore, Hoshiarpur, and Gurdaspur, and ranged from 40 to 65 per 1,000; while only in seven districts was the mortality below 25 per 1,000. Young children were the chief sufferers, more than a half of the total deaths having occurred among those under five years of age.

Of the chief diseases cholera was less prevalent than usual, and caused 614 deaths, or 0·03 per 1,000 against a previous five years' mean of 0·36. The disease was

confined to a few districts, and only in Kangra did it appear in an epidemic form causing 526 of the total cholera deaths. Out of a total of 35,972 villages in the province the entire mortality was returned from 97. The Sanitary Commissioner (Dr. Bellew) reports that the history of the disease at Kangra was not available.

Small-pox was much more prevalent than in 1883. The deaths numbered 16,416, or 0·87 per 1,000, against 12,103, or 0·64, in 1883. All the districts were affected, Karnal recording the highest death-rate, viz., 4·20 per 1,000; but this rate was exceeded in some of the towns, in two of which, Jagadhri and Shahabad, the mortality reached 5·77 and 5·87 per 1,000 respectively. Of the total deaths, 4,713 occurred among children under one year of age and 10,772 between the ages of one and twelve.

More than two-thirds of the total deaths of the province were registered under fevers. These amounted to 465,556, or 24·71 per 1,000, a greater number than in 1883 by 159,371, or 8·46 per 1,000. The fever mortality of 1884 was also greater than in any previous year, excepting the scarcity year 1879, and was attributed chiefly to the excessive rainfall. The districts most affected were Ludhiana, Umballa, and Karnal, which recorded death-rates of 52·95, 45·12, and 40·38 per 1,000 respectively. The city of Karnal suffered most severely, and returned the enormous fever death-rate of 70·42 per 1,000 of its population numbering 23,133. The Deputy Commissioner reported that hardly an inhabitant escaped fever, and that death must have visited almost every family. In these trying circumstances, it is reported, the Civil Surgeon and his staff did good work in administering medical relief, and great services were rendered by the Deaconness and ladies of the Zenana Mission, who won the gratitude of all by their indefatigable exertions and ready sympathy. "The practical teaching of the year's experience is," the Army Sanitary Commission state, "that more activity is required in improving the sanitary condition "of villages, including the draining and general improvement of village sites, and "that these district fever-rates should be studied with reference to the influence of "drainage defects on the public health, and the means of their removal, so far as this "may be practicable."

From bowel complaints 18,346 deaths were registered, equal to 0·97 per 1,000 of population, against 14,607, or 0·77, in 1883. The mortality was generally diffused over the province, but its incidence was local, for only 11 per cent. of the villages returned deaths.

North-Western Provinces and Oudh.

Each year witnesses to an improvement in the registration of births and deaths in the North-Western Provinces and Oudh. General registration was introduced into the provinces in 1879, when the recorded birth-rate was 28·69 per 1,000; since then the ratio has been gradually increasing, until, in 1884, it stood at 43·77 per 1,000, the number of births registered being 1,930,961 against 1,801,401, or 40·84, in 1883. The improvement seems to have been general, for only three districts, Dehra Dun, Kumaun, and Allahabad, showed imperfections. These three districts also returned the lowest death-rates.

The year 1884 was, on the whole, an unhealthy one, which was due to a considerable extent to an excessive rainfall during the autumn months. The deaths were more numerous than in any year since 1870, excepting the famine year 1879, and in 1884 numbered 1,555,342, or 35·26 per 1,000, against 1,216,297, or 27·57, in 1883. So high was the mortality in some parts of the provinces that nine districts returned death-rates in excess of the birth-rates. Nearly a third of the total deaths occurred among children under one year of age.

Cholera was more prevalent than in 1883, and the deaths rose from 18,160, or 0·41, in that year to 30,143, or 0·68 per 1,000 in 1884. All the districts suffered with the exception of Garhwal and Lalitpur, but the disease was epidemic only in the trans-Jumna districts of Hamirpur, Banda, Jalaun, and Jhansi, especially in the two first. The Sanitary Commissioner (Dr. Planck) observes that "this epidemic prevalence may, perhaps, be "considered a continuance of that recorded in Banda during the years 1883 and 1882, "which appeared to take its origin from the Allahabad Kumbh fair of the year last "mentioned." But the Government of India in their Orders on the Sanitary Commissioner's Report point out that from the facts adduced in Dr. Cuningham's Report for 1882 it appears clear that no such foundation exists. "The sanitary condition of "the towns and villages of Banda," they say, "coupled with scanty and bad water-"supply during certain seasons of the year, is sufficient to account for the persistence "with which the disease has clung to this district during the last three years. The "true safeguard is the removal of these localizing influences."

The mortality from small-pox was greater than in any year since 1876. No less than 202,541 people perished from the disease or in the proportion of 4·59 per 1,000 of population, against 138,641, or 3·14, in 1883. The epidemic was spread over the entire province, but its severity was mainly confined to the districts of Oudh, five of which yielded death-rates ranging from 19·35 to 10·69 per 1,000. The Lieutenant-Governor in his Orders on the Sanitary Commissioner's Report says: "The liability "of Oudh to small-pox epidemics is without doubt due to the failure to extend "vaccination in that province. It may be hoped that this state of things will now "be remedied. Signs are not wanting that the severe mortality of the last two years "has had some effect in increasing the belief in the efficiency of vaccination, and very "commendable efforts have been made in some districts to further the operations of "the Vaccination Department."

From fevers the registered deaths amounted to 1,074,097, or 24·35 per 1,000, against 830,258, or 18·82, in 1883. The mortality appears to have been very high in irrigated districts, 12 of which returned an average death-rate of 35·33 per 1,000. The Government of India notice that Dr. Planck reiterates his statements "that irrigated districts "afford higher death-rates from fevers than others; but as he adds that this difference "is especially marked 'in years characterized by plentiful autumn rainfall,' and thus "renders it uncertain how much of the fever-inducing cause may be separately "attributed to either condition, he has been asked to confine his attention to the "discovery of any direct relationship which may exist between canal irrigation and "the prevalence of fevers."

Bowel complaints accounted for a larger number of deaths than in the previous year, namely, 76,508, or 1·73 per 1,000, against 66,530, or 1·51, in 1883; but the mortality was not excessive when compared with a previous five year's average of 1·79.

Central Provinces.

The vital statistics of the Central Provinces for 1884 show that 368,086 births were registered during the year, being in the ratio of 41·75 per 1,000 of population, against 357,864, or 40·59, in 1883. In no district was the birth-rate below 37 per 1,000, which indicates improvement in registration; and everywhere births were more numerous than deaths, the excess for the province being 14·4 per 1,000. The registered deaths fell from 304,763, or 34·56 per 1,000, in 1883 to 240,714, or 27·30, a decrease of 64,049, which the Sanitary Commissioner, Dr. J. H. Loch, attributed to the general healthiness of the year. Nearly a third of the total deaths occurred among children less than a year old and more than half among children under five years of age.

Cholera was remarkably little prevalent, there being only 149 deaths registered during the year, which is a great decrease on 16,235, the number recorded in 1883, and a smaller mortality than in any year since 1874. Of the total deaths, 84 occurred in Nimar district and 29 in Chanda, the rest being spread over six other districts. Only 40 of the total 27,674 villages of the province were affected. At the two great fairs of the province, Birman and Ramtek, cholera was present only in the former, where there were five cases and four deaths among the pilgrims.

Small-pox, on the other hand, was more prevalent than usual, and gave rise to 4,882 deaths, or 0·55 per 1,000, a higher ratio than in either of the three preceding years, but considerably below the mean of the previous five years ending 1883, viz., 1·04 per 1,000. The disease prevailed in every district of the province, and it affected more than 7 per cent. of the villages. Of the total deaths, 1,968, or 40 per cent., occurred among children under one year of age, "a result which appears to show," the Army Sanitary Commission remark, "that too small a proportion of the children born is "vaccinated within the year."

From fevers 145,342 deaths were registered, equal to 16·48 per 1,000 of population, against 175,119, or 19·86, in 1883. In nearly every district the death-rates were lower than in the previous year, and in several instances the decrease was large. The highest district ratio was 25·28 in Narsinghpur and the lowest was 6·66 in Nagpur.

The deaths registered under bowel complaints amounted to 21,991, or 2·49 per 1,000, against 26,623, or 3·02, in 1883.

Berar.

The new system of registering vital statistics which was introduced into Berar on 1st January 1883 is reported to be working well and efficiently. It is, however, still defective in several towns, but measures have been taken to ensure improvement. In 1884 the registered births numbered 108,725, or 41·3 per 1,000, as compared with 105,921, or 40·3, in 1883. In every district the birth-rates exceeded the death-rates, the excess varying from 14·2 per 1,000 in Akola to 19·3 in Buldana; the average for the province was 16·7 per 1,000.

The year 1884 was exceptionally healthy and had the effect of causing a considerable diminution in the death-rate. Coming after a year of great mortality this is a matter for congratulation. Deaths were registered to the number of 64,508, or 24·63 per 1,000, being 70,273, or 26·7, less than in 1883. Young children were again the chief sufferers, no less than 55·4 per cent. of the total mortality having occurred among those under five years of age. From all the chief diseases there were fewer deaths, a sure indication that the year, on the whole, was a healthy one.

It is satisfactory to note that cholera in an epidemic form was absent from the province during the year. Only 87 deaths were registered from the disease, against 27,897, or 10·60 per 1,000, in 1883, and these were confined to 19 villages in the districts of Ellichpur, Akola, and Buldana. In his remarks upon the various theories in regard to the cause and spread of cholera the Sanitary Commissioner says: "These "variations in the intensity of cholera outbreaks from year to year occur everywhere "throughout India, as may be seen from the Sanitary Reports of the various "provinces, and would indicate that something beyond the cholera bacillus, a con- "taminated water-supply, or human intercourse, is necessary to explain this difference "between the results of different years . . . . Whatever these conditions or "influences may be which originate and favour the spread of cholera, they still remain "to be discovered, or the cause explained why one season should be healthy and "another unhealthy. We know, however, that much can be done beforehand to ward "off the ravages of cholera when it does come, by attention to the sanitary condition "of our towns and villages, for experience has shown that as dirt invites and fosters "cholera, so, on the other hand, a good sanitary state greatly lessens the liability to "attack."

Deaths from small-pox also show a considerable decrease, the registered number for 1884 being 615, or 0·2 per 1,000, against 3,853, or 1·46, in 1883. The disease prevailed in every district and through each month of the year, but it was fatal only in 202 villages out of 5,501. Of the total deaths, 212 occurred among infants under one year of age, and 384 among children between one and ten years. Statistics show that the mortality from this disease has greatly diminished since vaccination was introduced and extended, "but the large death-rates at the younger ages show," the Army Sanitary Commission observe, "that it is not sufficient to have a high general "vaccination rate, unless it can be shown that the high rate is due to operations "performed in the first year of age."

Fever deaths were less numerous than the average for the previous five years and less by 23,044 than in 1883, the number registered in 1884 being 30,551, or 11·6 per 1,000, against 53,595, or 20·37, in 1883. According to districts, Wun, as usual, recorded the highest fever death-rate (15·8), and the minimum mortality (6·9) was registered in Basim. No explanation is given why these two districts should persistently return the highest and lowest fever death-rates. The Army Sanitary Commission suggest that the matter should be inquired into. "All that can be done with the case as it "stands," they remark, "is to point out the probability of local drainage defects "leading to local causes of malaria, as influencing the amount of fever."

Deaths registered under bowel complaints were 9,319, or 3·5 per 1,000, against 19,044, or 7·24 per 1,000, in 1883. There was the same diversity in the rates of the different districts as from fevers.

Assam.

Satisfactory progress was effected in the registration of births and deaths in Assam during 1884, especially in the latter, but the results are still far from accurate. Births were registered to the number of 120,483, or 26·61 per 1,000, against 108,269, or 23·91, in 1883. The ratio for the year under notice was made up of extremes varying from 19·38 per 1,000 in Lakhimpur district to 41·65 in Goalpara. The registered deaths numbered 132,992, or 29·37 per 1,000, against 122,932, or 27·14, in the previous year. In all districts but Cachar the deaths exceeded the births, the provincial excess amounting to 12,509, or 2·76 per 1,000. "It would hence appear," the Army Sanitary Commission remark, "that the registration of deaths is better done than that of births, and not "that the population has diminished." The results obtained in the tea gardens also indicate improvement in registration, the birth-rate having risen from 26·70 per 1,000 in 1883 to 31·66 in 1884, and the death-rate from 30·07 to 40·91. This, however, is a very high rate of mortality compared with that of the general population of the province, and is attributed to the coolies being almost entirely imported, and accordingly, subjected to climatic conditions, often differing considerably from those to which they have been accustomed in their native places. In the opinion of the Sanitary Commissioner, Dr. Eteson, the high mortality was partially due to preventable

causes. This subject, the Government of India state, should receive careful attention.

Nearly three-fourths of the excess mortality of the year was contributed by cholera, the disease having been unusually prevalent during 1884 and the death-rate the highest on record. The deaths from cholera numbered 22,276, or 4·92 per 1,000, against 14,908, or 3·29, in 1883. Every district suffered, but the disease prevailed with special severity in Nowgong district, which returned a cholera mortality of 8·95 per 1,000. The coolies in the tea gardens also suffered very severely from cholera, the death-rate (8·3 per 1,000) being nearly double the provincial rate. The tea planters ascribed this prevalence to newly imported batches of coolies, while at the same time they admitted that the coolies left the steamers in good health, that the disease was prevalent generally in the district, and that some time elapsed before the coolies became affected. "The "facts appear to show," the Army Sanitary Commission observe, "that there are "causes of some kind in the tea gardens themselves which predispose the coolies to "attacks of cholera during epidemic seasons, and we would suggest that rigid inquiry "should be made into the conservancy arrangements, water-supply, and drainage of "the localities where the workpeople live." The immigrant coolies on board river "steamers appear to have been remarkably exempt from cholera compared with the general population, the death-rate being 2·6 per 1,000, which was the lowest on record. This Dr. Eteson attributes to the improved arrangements at Dhubri depôt, to the avoidance of overcrowding on board the steamers, to the introduction of an accelerated service of mail steamers, whereby the voyage has been shortened from sixteen to four or five days, and to improved sanitary arrangements on board.

Small-pox was less prevalent than in 1883, the registered deaths having fallen from 6,162, or 1·37 per 1,000, to 4,781, or 1·05. Darrang and Cachar districts again recorded the highest death-rates, namely, 1·35 and 2·37, but both showed a decrease compared with the previous year. Of the total deaths no less than 3,365 were of children under 12 years of age. It is stated that the propagation of small-pox in Assam is largely due to the general practice of inoculation. Dr. Eteson, however, thinks that the statistics of the year furnish indications that vaccination is repelling the disease in some localities.

The mortality from fever was also less than in 1883, the number of deaths having decreased from 67,494, or 14·90 per 1,000 to 66,527, or 14·69. In the more populous districts the death-rates ranged from 8·81 per 1,000 in Lakhimpur to 38·03 in Goalpara; but in such a climate as Assam these figures, in the opinion of the Army Sanitary Commission, only show the state of the registration and not the fever prevalence. The high fever death-rate of Goalpara district is again attributed to the prevalence of the fever locally known as *kala azar*, described in Vol. XVII., p. 16. During the year under report the attention of the Chief Commissioner of the province was directed to the water-logged condition of tracts specially affected with sickness in this district, and measures were being taken to ascertain the facts by a professional survey. There was a marked absence of any connexion between the rainfall of the year and the prevalence of fever. The Army Sanitary Commission notice that "in Goalpara district, with a "rainfall of 65·25 inches, the fever death-rate averaged 38·03 per 1,000, while in "Sylhet, with a rainfall of 144·11 inches, the fever death-rate was 11·64 per 1,000, "affording a clear indication that the amount of fever depends on other factors than "the amount of rain." The Sanitary Commissioner states: "The body of registrars "name fever as a cause of death simply because there has been a symptomatic "increased temperature sensible to an ignorant observer. Nearly half the deaths of "the province are put down to fevers. Perhaps one-third of these are climatic or "malarial, and due to natural causes under which the people must live and die for "generations to come: a third is probably due to the habits of the people, their "insufficient clothing and bedding, their exposure, their food, and privations; and the "remaining one-third would, under a more perfect system of registration, be entered "under other classes of disease."

The number of deaths ascribed to bowel complaints was the largest on record, namely, 16,157, or 3·56 per 1,000, against 14,474, or 3·19, in 1883; but the Sanitary Commissioner considers registration under this head very imperfect, "which we must hope," the Army Sanitary Commission observe, "to be the truth of the matter, for the "year's statistics give a death-rate among the coolies from bowel complaints of 10 "per 1,000."

The results of the registration of births and deaths in British Burma for 1884 were again very unsatisfactory. A new system of collecting vital statistics was, however, British Burma.

introduced in some districts late in the year, and in others from the commencement of 1885, and better results are expected. Births were registered during 1884 to the number of 82,783, or 22·66 per 1,000, against 83,735, or 22·92, in 1883; and the loss to population by deaths amounted to 69,234, or 18·95, against 53,583, or 14·67 per 1,000. The imperfectness of registration is further shown in the very great difference between the urban mortality (36·65) and the rural mortality (16·61).

From all the chief diseases more deaths were registered than in the previous year. Cholera prevailed with great severity, and gave rise to 5,515 deaths, or 1·51 per 1,000, against 2,186, or 0·60, in 1883. The towns suffered more than the villages, the death-rate of the former being 2·68 per 1,000 and of the latter 1·36. But although the disease was very prevalent it was confined in area, for only 227 villages out of a total of 14,811 were affected. The general result of the year's experience, the Army Sanitary Commission remark, "may be said to be that, during cholera periods, two "factors are included, the epidemic, over which we have no control, and local insani-"tary conditions, which we can remove or mitigate. It is the same experience which "is reproduced in every outbreak of cholera, and it carries its lesson with it."

From small-pox 6,102 deaths were registered, equal to 1·67 per 1,000 of population, which was the largest number on record, and exceeded the mortality of the previous year by 5,427, or 1·49. The disease was most fatal among children, no less than 84 per cent. of the total deaths having occurred among children under 12 years of age; it prevailed, also, with greater severity in the towns than in the rural circles, for the former yielded the high death-rate of 4·86 per 1,000, while the ratio of the latter was 1·25.

To fevers were ascribed 29,514 deaths, or 8·08 per 1,000, against 26,283, or 7·19, in 1883. In discussing the influence of climate on fever, the Army Sanitary Commission compare the mortality in each of the four divisions of the province with the average rainfall of the year. "At first sight," they say, "it would appear that the more rain "the more fever was the rule in Burma; but this is really not so, and the causes of "fever mortality must be sought elsewhere. There are whole districts of country in "which the fever-rate is remarkably low, that is, if the registration could be depended "on, and it is not improbable that some of the mortality may be due to the usual "local insanitary conditions as well as to malaria."

Bowel complaints yielded 3,719 deaths, or 1·02 per 1,000, against 2,781, or 0·76, in 1883, and the entire mortality is reported to have been returned from 131 villages, less than one per cent. of the total number.

IV.—JAILS.

The health of the prison population of India during 1884 was, on the whole, more favourable than in the previous year. Sickness was somewhat more prevalent, the admissions into hospital having risen from 996 per 1,000 of average strength in 1883 to 1,025, and the daily sick rate from 36 to 37 per 1,000; but the mortality fell from 31·37 to 29·11, which is the lowest death-rate on record, and less by 7·13 per 1,000 than the average of the five years 1872–76, and 3·39 below the average of the years 1877–81. This satisfactory diminution in mortality, the Army Sanitary Commission observe, "has co-existed with reduction in the prison population, which means less crowding "and more ventilation." Sickness and mortality in 1884.

Dysentery and diarrhœa were the chief death causes, yielding 9·73 of the total death-rate; respiratory diseases and phthisis followed with 7·38 and fevers with 2·97 per 1,000. From cholera the death-rate was 1·43 per 1,000, against a previous 10 years' rate of 3·46. "This reduction in the midst of a severe cholera epidemic," the Army Sanitary Commission remark, "affords evidence of good work done in many "jails."

The following statement gives the leading facts in connexion with the health of the jails of the various provinces of India for 1884 as compared with 1883:—

Provinces.	1884. Ratio per 1,000 of Average Strength.			1883. Ratio per 1,000 of Average Strength.		
	Admissions.	Daily Sick.	Deaths.	Admissions.	Daily Sick.	Deaths.
Bengal	1,420	50	50·41	1,498	50	52·21
Madras	765	29	20·55	861	32	29·87
Bombay	702	26	34·91	734	27	34·33
Punjab	1,131	27	28·04	951	22	29·11
North-Western Provinces	681	26	20·86	563	23	18·76
Central Provinces	932	32	42·02	979	36	76·97
Berar	486	11	8·72	558	14	8·49
Assam	2,109	56	81·19	2,125	56	43·12
British Burma	936	37	30·28	1,159	39	28·94

The vital statistics of the prison population of Bengal were, on the whole, more favourable in 1884 than in the preceding year, and the death-rate was much below the average. The admissions into hospital were in the ratio of 1,420 per 1,000 against 1,498 in 1883, the daily sick rate was the same, 50, and the mortality 50·41, or nearly 2 per 1,000 less. Both in 1883 and in the year under report, much was done to improve the condition of the jails and of their inmates. There are, however, it is stated in the Government Resolution on the jail report, many predisposing causes to "sickness against which no measures taken by Government or the Inspector-General can "adequately provide without the help of careful and intelligent supervision by super-"intendents of jails. Now that so much has been done in the way of providing "improved accommodation, good water, ample food, and sufficient clothing for our "prisoners, Sir Rivers Thompson thinks that unremitting watchfulness and care on "the part of these officers will have more effect in reducing the sickness and mortality "than any further measures which the Government can adopt." Bengal.

Among the convict class the death-rate was 59·4 per 1,000 of average strength against 53 in 1883. These prisoners suffered chiefly from dysentery, diarrhœa, fever, general debility, and respiratory diseases. Cholera was not exceptionally prevalent, but accounted for 57 of the total 691 deaths, being in the ratio of 4·1 per 1,000 of average strength. Twenty-four jails out of 45 were quite exempt from the disease, while in the outside population it caused great havoc, and in 29 jails there were no cholera deaths. The jails which suffered most were Rajshahye (11 deaths), Gya (9), Monghyr (6), and Alipore (5).

Although showing an improvement on previous years, the Bengal jail death-rate still continues very high. To some extent this would appear to be due to the bad state of health of prisoners on admission. The Inspector-General reports that "there were "1,084 prisoners in jail awaiting trial on the 1st January 1884, and 28,830 were "received during the year. The daily average number in jail was 1,170, and each,

" on an average, was in jail only 14·86 days, and yet 49 died before their cases were " decided. These deaths can hardly have been due to any of the conditions of prison " life. However injurious they may be, they could hardly kill in 15 days." He further states that "out of 720 prisoners who died during the year only 274 were " considered on admission to be in good health, and 212 were positively bad."

Of the 45 jails in the province the following 18 recorded death-rates above the general average:—

Jails.	Death-rate per 1,000 of Average Strength.		Jails.	Death-rate per 1,000 of Average Strength.	
	1884.	1883.		1884.	1883.
Rungpore	283·4	196·9	Bhagulpore, *District*	71·5	45·0
Julpigoree	162·6	261·9	Balasore	70·1	—
Mymensingh	153·0	56·5	Monghyr	66·3	59·2
Bogra	134·5	148·0	Dacca	63·1	78·8
Purneah	115·3	37·8	Midnapore, *District and Central*	58·1	104·5
Rajshahye, *District and Central*	110·8	63·2	Furreedpore	57·6	31·2
Singbhoom	102·2	16·6	Backergunge	54·2	53·6
Burdwan	80·7	47·6	Nuddea	53·3	118·3
Dinagepore	79·7	107·6	Alipore	51·1	47·6

Regarding the high death-rate at Rungpore, the Inspector-General notices that it is based on a daily average population of only 230, and therefore every death which occurred represents more than 4 per 1,000. And in Singbhoom the death-rate is calculated on a daily average population of less than 75, and represents 9 deaths, each counting as 11 per 1,000. Of the first seven of the above jails, Rungpore, Julpigoree, and Bogra appeared in a similar list in the previous year. Out of 59 deaths at Rungpore 33 were due to bowel complaints and 5 to fever. At Julpigoree 10 out of the total 17 deaths were due to bowel complaints and 2 to cholera. Bowel complaints were also the principal death causes at Mymensingh, contributing no less than 33 of the total deaths; and the remaining four jails of the first seven suffered in a similar manner. It is again noticed in the Resolution of the Bengal Government on the Jail Report that the primary cause of the high rate of mortality in the jails of Eastern Bengal "is the diseased condition of the low class of people to which the prisoners " generally belong, and that no known preventable causes exist in the jails. Every " sanitary precaution has been and will continue to be taken for preserving the health " of the prisoners, and although this has not been hitherto always attended with " decided success, the Lieutenant-Governor still hopes that, with perseverance and by " utilizing the knowledge obtained from special inquiries, a real improvement is " gradually being effected in the health of the prisoners."

Madras.

The general health of the jail population in the Madras Presidency during 1884 was good. Among all classes of prisoners the death-rate was in the proportion of 20·55 per 1,000 of average strength against 29·87 in 1883. In eight jails out of 33 there were no deaths, but in seven, all being district jails, the mortality was still above 40 per 1,000. Although cholera was prevalent in all the southern districts of the Presidency, the only jails affected were Trichinopoly, Tanjore, and Cuddalore; altogether nine deaths were recorded from this disease. The highest death-rate from all causes was recorded at Tanjore jail (60·81), which had long been unhealthy; the construction of the new cellular jail was reported to be completed, and it was hoped that before long the old jail might be entirely evacuated. In Trichinopoly jail, which was the subject of a special inquiry in 1882, there was an immense improvement in the health of the convicts, the death-rate having declined from 176·77 in 1882 and 55·14 in 1883 to 23·21 in the year under review. This jail is now under the charge of a medical officer.

Among the convicts there were 149 deaths, equal to 20·70 per 1,000 of average strength against 29·49 in 1883. Bowel complaints contributed 36 to the total deaths amongst this class of prisoners, anæmia and general debility following with 26. From cholera there were only 7 deaths against 13 in the previous year.

In discussing the health statistics of the Madras jails (Appendix, p. 167), the Army Sanitary Commission notice the small mortality from epidemic disease as compared with that of the civil population. "Our object in introducing these comparisons," they say, "is simply to call attention to the fact that 7,000 inhabitants out of the population

" of the Presidency have had their sanitary surroundings so improved as to have nearly " escaped epidemics, showing that the work of improvement is a practical one, and to " raise the question why it is that the remainder of the population not in jails suffer so " greatly, and why so little effort has been made to improve their sanitary surroundings."

Bombay. The general health of the prison population of the Bombay Presidency during 1884 was also good, the ratio of admissions to hospital and of daily average sick being smaller than for many preceding years, while the death-rate showed a slight increase from 34·33 to 34·91 per 1,000 of average strength. This increase of mortality was chiefly due to the exceptionally high death-rate (107·9) at Nara district jail. On two occasions during the cold season of the year this jail, which was of a temporary structure and movable, was destroyed by fire, including all the warm clothing; consequently the prisoners were greatly exposed. The jail has since been reconstructed on a different principle, and various improvements connected with its re-organization and sanitary arrangements have been carried out, which it is hoped will lead to better results in the future. The total deaths in the district and central jails during the year numbered 249, all but one having occurred among the convict class. Of the chief death causes, respiratory diseases were more fatal than any other, the deaths numbering 58, or four more than in 1883; dysentery and diarrhœa followed with 50 against 43; while from fevers the deaths fell from 33 in 1883 to 26, and from cholera from 15 to 4. As usual, nearly half the deaths occurred among convicts in the first six months of their imprisonment. In almost all the jails of the Presidency the ratio of mortality showed very favourable results, excepting those in Sind province, which contributed more than a half of the total deaths.

Punjab. In the Punjab jails sickness was slightly more prevalent and more widely spread in 1884 than in the previous year; but it was of a less severe character, as shown by the decrease in mortality from 29·11 per 1,000 of average strength in 1883 to 28·04, a ratio which compares favourably with that of the free population during 1884, namely, 35 per 1,000. In 19 out of the total 36 jails, however, the mortality was greater than in 1883, the greatest increase being in the Delhi jail, where it rose from 24·39 per 1,000 of average strength to 74·41. On the other hand, there was a decrease of mortality in 16 jails, while in four there were no deaths. "The very low death-rate of the " Rawalpindi jail (10·17)," the Inspector-General reports, "is worthy of note. This " jail has, in former years, suffered from most destructive epidemics. Last year it " was one of the healthiest in the province, a result which, I believe, is in some measure " due to the efficient supervision of Surgeons-Major Massy and Bennett, who have " bestowed the greatest care on all arrangements that affect the health of the prisoners." All the jails which exhibited the greatest sickness and mortality lie between Lahore and Delhi, and were visited, it is reported, by one common epidemic of malarious fever, which was equally, sometimes to a greater extent, prevalent among the free population, and which was attributed to special climatic causes. The chief causes of mortality in the Punjab jails were respiratory diseases, chiefly pneumonia, from which there were 89 deaths, or 17 less than in 1883. From intermittent fever the admissions were nearly one-half more numerous than in 1883, but the deaths from it fell from 55 to 27; on the other hand, dysentery and diarrhœa caused 65 deaths, or 25 more than the number of the previous year. Deaths from anæmia and general debility also rose from 24 to 30; but both numbers are considered very small for the population, "a fact which " indicates a satisfactory state of health of the prisoners." There was very little cholera in the province during the year, and there were only two cases in the jails, neither of which proved fatal.

Among the convicts the deaths numbered 312, equal to 28·87 per 1,000 of average strength against 29·82 in 1883. Nearly a third of the deaths occurred among convicts who had been less than six months in jail.

North-Western Provinces and Oudh. There was more sickness among the prisoners of the North-Western Provinces and Oudh than in 1883, and there was also an increase in the proportion of deaths, though the death-rate, on the whole, continued low. The admissions into hospital among prisoners of all classes rose from 563 per 1,000 in 1883 to 681 in 1884, and the death-rate from 19·76 per 1,000 of average strength to 20·86. The increased mortality was entirely due to bowel complaints, from which the number of deaths amounted to 152, or 46 more than in 1883. Among individual jails the highest mortality was recorded at Banda, namely, 150 per 1,000, which was attributed to dysentery and other sequelæ of fever, the prisoners being predisposed to illness by the scorbutic taint which largely

prevailed in the preceding year. The Almora jail also returned a mortality of over 100 per 1,000 (102), and in nine other jails the death-rates exceeded 30 per 1,000. It is satisfactory to learn that "in a number of the jails that have had a reputation for "unhealthiness measures have been taken for the improvement of their sanitary "conditions by increasing the accommodation, removing obstacles to ventilation, and "arranging for a better water-supply; and these improvements will, it is hoped, "maintain the very creditable position that has for some time been held by the jails "of these provinces as the healthiest in India." Although cholera was generally prevalent in the province all the 52 jails but three were exempt from the disease. There were 13 cholera deaths, 11 of which occurred in the Meerut central prison, and one each at the Agra and Banda jails. Of the total 451 deaths from all causes all but 30 occurred among the convict class.

Central Provinces.

The vital statistics of the Central Provinces jails for 1884 show that, on the whole, the prisoners enjoyed better health than in the previous year. The number of admissions to hospital were much fewer, the daily average sick less, while the number of deaths (145) had decreased by nearly one-half the total of 1883. This reduced mortality was mainly due to the great decrease in the deaths under bowel complaints from 160 to 56. Another satisfactory feature was the entire exemption of the jails from cholera during the year, and their freedom also from small-pox and enteric fever. In 1883 the most unhealthy jail was Raipur, which recorded 112 deaths, or 145·0 per 1,000, but in the year under notice the mortality had decreased to 35, or 58·7 per 1,000. There were 138 deaths amongst the convicts, equal to 42·40 per 1,000 of average strength against 274, or 73·2, in 1883. Of the six jails in the province with an average population exceeding 100, Sambalpur jail recorded the highest convict mortality, namely, 62·18 per 1.000; but the greatest number of deaths took place in the three jails of Jubbulpore, Nagpur, and Raipur, together yielding 108 of the total 138 convict deaths. In these jails the average population exceeded 500.

Berar.
